has just been defeated by trickery and fraud; but she is rising in her might, and bids fair to overthrow the giant before many months have passed. Are you, my friends, whose eyes rest on these pages, ready to show the courage of David in olden times, and declare as he did, "Thou hast defied the armies of the living God"?

"WHERE THIEVES BREAK THROUGH AND STEAL," ETC.

Mr. A. I. Root:—Greetings to you in Jesus' name. I am a regular reader of GLEANINGS and also a preacher beekeeper. Two years ago I took off a little over 2000 lbs., part extracted and part section honey, from 16 colonies, spring count, but last year the drouth hit us so that I got no surplus at all; and instead of the 22 colonies with which I started out in the spring I had only 12 left. Something happened to me last fall that was enough to make "even a preacher" feel a little cross. Some rascal of a beekeeper got into the place where I had my bees, and stole the three best colonies out of fifteen that I was getting ready for winter. They were two-story high, and weighed at least 100 lbs. each. That is worse than stealing honey. I offered a nice reward, but never got any trace of them.

I read with interest Our Homes and Health Notes in GLEANINGS. I see that you have trouble to get your hands clean after getting black auto grease on them. My boys are just now manufacturing a hand-cleaner that I believe will solve this problem for you much more pleasantly than you are now trying to solve it according to yours in GLEANINGS for March 15. I am sending you a 1-lb. 10-cent box to-day. Use it according to directions, and see how easily the grease can be removed from the hands. We are making it from our own formula, and it is the best thing out for such purposes.

My oldest son is now attending Western Union College at Lemars, Iowa, preparing himself for the ministry. The other two are still at home attending high school. What they make out of the soap proposition will be used to put them through school. If after a thorough test you can say a good word for this article I am sure it will be appreciated.

My bees came through the winter finely. When I set them out two weeks ago, several of the colonies had a few young bees hatched out, and every one of the twelve had patches of brood in from one to three frames. This is the first time I ever had hatching brood in the cellar.

Geneseo, Ill., April 1. GEORGE A. WALTER.

The soap is certainly ahead of anything else I ever got hold of. When I am in a hurry it is certainly a great help. But what you say about thieves stealing your bees just to get the *honey* worries me. If, in answer to your reward offered, he should be caught and punished, the good to the world would not *compare* with getting him converted, say, by Billy Sunday or some "beekeeper preacher." "He that converteth a sinner from the error of his way, shall save a soul from death, and shall hide a multitude of sins." My good brother, have not you and others permitted *saloons* to flourish unhindered in your midst?

HIGH-PRESSURE GARDENING

EARLY OHIO POTATOES DOWN IN FLORIDA, ETC.

Up here in the North my favorite potato for years past has been the Early Ohio. A year ago I had trouble about getting seed. I finally got some for a big price, but it was poor seed at that. They were planted in our garden right under the irrigation-pipe, and made a magnificent growth; but potatoes had been grown in this garden for years past. Besides, it has been heavily manured with stable manure. We had a good yield; but they were the scabbiest lot of potatoes I think I ever saw. The garden was plowed before I returned from Florida, and was plowed when it was wet. The potatoes squeezed themselves into all sorts of shapes and among the lumps and clods; and after I got our overhead irrigation, as you may remember, the potatoes took a second growth. Mrs. Root suggested we should give them all to the pigs and chickens; but when we found the *quality* was so much better than any nice smooth potatoes we could buy, we finally decided to use them for the table, paring off the scab and the knobs that had started out with a second growth. Well, these Ohio potatoes, notwithstanding their forbidding looks outside, cooked up so dry and floury that we decided to take a peck with us to Florida. I think they were dug just before leaving, about Nov. 1. As we had other new potatoes, some of the Early Ohio, brought from Ohio, did not get used till January 1; and to our surprise some little sprouts had started; and Mrs. Root suggested that we plant them and see what the *Florida* crop would be. I cut them to one eye so as to make them go as far as possible. They came up very promptly; and from their great luxuriance they attracted the attention of visitors all winter, and along in April they were ready to dig. They made a slow growth because of the frequent cold rains; but it was one of my happy surprises to find the cleanest, smoothest, handsomest Early Ohio potatoes I ever got hold of.

Let me repeat what I have said several times. In Florida, at least in Manatee County, there is no such thing as potato bugs. They have not been "invented" there yet; and there is also no such thing as the flea-beetle that disfigures and eats holes through the potato leaves all over the North. And there is also no such thing as the potato scab—at least not the same kind of scab we have here in the North. I took a basketful of the potatoes up to our Bradenton groceries, and everybody who caught

a sight of them wanted them. The quality was quite equal to the looks. But there was one drawback. The largest ones were more or less hollow. I suppose this was owing to the rapid growth. I think that this can, perhaps, be corrected by planting them so close that they will not grow very large.

Now just one thing more and I am through with my potato story, for the time being. These Early Ohio potatoes were dug about the middle of April. We brought some of them with us; and just now, May 18, some of them show evidences that they are going to sprout; and I think I am warranted in saying we can dig potatoes here in the fall, carry them down to Florida, and by the first of January they will be ready to plant. Perhaps I should explain that they stood on a north porch—the coolest place we could find, through November and December. Well, the potatoes grown in Florida may also be *brought north*, and, if exposed to light and warmth, they will be ready to plant again in thirty days or more, thus getting two good crops in one year by moving them from the North to the South.

One thing more: The poor scabby potatoes grown here in the North, if planted in the loose soil in Florida, will give a nice clean crop. There may be some danger, it is true, of introducing the scab in the Florida soil; but if necessary the treatment with formalin would correct this.

Now just one thing more: A neighbor of mine said he had planted potatoes in Florida in September, and had a nice yield. Well, I have planted them from November 1 to along in February, and had a satisfactory yield; and I am told that potatoes planted in April often give good yields in Florida; and I think it quite likely, when we *learn how*, we can plant Irish potatoes in Florida *every day in the year, and harvest* them every day in the year, as we do with the dasheens.

MAKING TWO TREES GROW WHERE NONE GREW BEFORE; SOME GOOD NEWS IN REGARD TO JAPANESE CHESTNUTS.

Dasheens, no doubt, are all right; but don't you think a few words on trees and arbor culture occasionally would help a worthy cause? To make two trees grow where none grew before is a part of my mission in life.

If the old adage be true, that "he is a benefactor of his kind who causes two blades of grass to grow where but one grew before," what shall we say of him who causes two trees to grow where none grew before?

Some one has said it would pay any state to hire a forceful man to go up and down the same, and simply say to every man he meets, "Don't plant soft

maples," to which might be added, North Carolina poplars, and other quick-growing and short-lived trees.

The beekeeper should plant, for sturdy beauty, sweet bloom, and large yield of honey the European linden—a hardy tree, and a joy to look upon; also the American tulip-tree, miscalled the tulip poplar, fairly rich in honey, and it bears much pollen—one of our most majestic trees, and pure American—the only relative being a species in Japan.

And then when you think of the boys and girls, do not forget the nut-bearing trees, including a few of the Japanese chestnuts, which are not affected by the blight, which is rapidly destroying the chestnut groves in this part of the country.

For decorative and formal effects plant the "gingko," the sacred tree of India and Japan. This is a rapid grower, known also as the "maiden-hair," because of the shape of its leaves. To my knowledge it thrives perfectly as far north as Newburgh, N. Y. For the same purpose the bald cypress should not be overlooked.

Now, brother farmers and bee-lovers, get busy and adorn that long lane or stretch of road, in which you are interested, with trees, and future generations will rise up and call you at least a lover of your kind.

C. H. GUBBINS.

Philadelphia, May 7.

The single statement in the above, that Japanese chestnuts are not affected by the terrible blight that threatens to destroy the American chestnut, is indeed good news if true. Will those who know something about it please give us further information? In years past I have mentioned my fondness for chestnuts, and I want to say now that I have enjoyed them after I have finished both breakfast and dinner, almost continuously since the new crop came in last fall. Just as soon as I get a lot of chestnuts they are put into an oven and roasted enough to destroy the chestnut weevil. This generally also prevents any tendency to mold in such a climate as that of Florida. But to make sure against mold as well as the weevil, we give them another roasting some time during the winter. With this protection I think I can have them almost if not quite all the year. In fact, I have a few now, May 11. Some of you may object because they are hard on the teeth. Well, I have a dentist, at least once a year, or oftener, look after my teeth, and see that they are in good trim. I have not had the toothache for years, and do not expect to have it. Well, when I get up from the table to go over the garden or out among the poultry, I put a handful of chestnuts in my left-hand coat pocket; and, no matter how hard they are, by taking time I can chew them until they are just a delicious creamy mass in my mouth, as Terry, Fletcher, and others have described, and in this way I greatly enjoy them. I am sure they are very healthful. Of course so much chewing calls forth an extra supply of saliva. Notwithstanding the blight last season, the price of chestnuts went away down in the Cleveland markets;

in fact, there was almost a "glut" at one time, in chestnuts. I bought a couple of quarts when first on the market, and then, later, put in a full supply for winter. I have planted a good many chestnut-trees already; but if what is said above in regard to the Japanese chestnut is true I intend to plant more; and this reminds me that I have both chestnut and pecan trees in bloom in our Florida garden for the first time this spring.

DASHEEN TUBERS ACROSS THE GREAT WATER NOT A FAILURE AFTER ALL.

It seems it is not a very difficult matter to send tubers, if properly seasoned and packed, to foreign nations after all. See the following letter from one of our missionary friends:

AMERICAN BOARD MISSION IN SOUTH AFRICA.
RHODESIA BRANCH.

Dear Friend, Mr. Root:—In response to your suggestion in GLEANINGS for Jan. 1, 1915, p. 41, that I let you know how I packed the amadumbe or dasheen tubers that I sent you, I will say that I too am forgetful, and cannot feel quite sure that I remember; but I think it was like this: I chose very small tubers (I think they had been dug some time), and wrapped each in enough paper so that several thicknesses, say five or six, should separate them from each other when packed. Then I packed them in a pasteboard box lined with corrugated pasteboard such as Burroughs, Wellcome & Co. place their bottles of tabloids in, and then wrapped this in paper.

I may remind you that you also succeeded, at least once, in sending dasheen tubers across the seas, for you sent some to me which arrived in fine condition, and their offspring are now doing well in my garden. So far I fail to see any difference between those that you sent to me and those that I sent to you; but we have not compared them very thoroughly, perhaps, as yet.

I am interested in what you say of cassava, Jan. 15, 1915. I have ten varieties of manioc growing in my garden. I wonder if any of them are identical with your cassava. Some of mine are sweet and some very bitter.

W. L. THOMPSON.

Mount Silinda, Melsetter, S. Rhodesia, March 17.

The amadumbe mentioned is growing finely in our Florida garden; and while it looks a little different from the Trinidad dasheen, the tubers when baked are substantially the same thing. Right near the South African dasheens is a queer-looking plant sent by a missionary from South America. It always attracts the attention of visitors because of its rapid growth and queerly mottled leaves. The manioc cuttings were received, and planted in our Florida garden. While we are considering the cassava and its value as a food product the following letter may prove to be of value.

CASSAVA HONEY, ETC., IN PARAGUAY, SOUTH AMERICA.

Dear Mr. Root:—When I read your remarks in GLEANINGS for January 15 on cassava as a food it occurred to me that you might be interested to hear about the ways in which that plant is used in Paraguay. The cassava (or, as it is called in this

country, "mandioca") is the staple food of the Paraguayan, whether he be Indian or mixed Indo-Spanish, and is, consequently, extensively grown all over the country. Of it the native makes his bread, his tapioca, and his starch, and on it he feeds his horses, cattle, pigs, and poultry, and even his dogs and cats. The ordinary method of cooking mandioca is to boil it after carefully removing all the thick peel; and so cooked it is a perfect substitute for the potato when eaten with any kind of meat. It can also be baked or roasted, as you describe, without peeling; and when peeled, cut in thin slices, and fried in deep fat, it is just as good as potato chips. Cold boiled mandioca also, cut up and fried, is delicious—much more so than potatoes so cooked—at least my husband and I think so now after five years' experience. You say that the plant you tested was of two years' growth. Here it is seldom left longer than one year, as after that time it does not cook soft and mealy, but assumes a waxy or soapy consistency after boiling. If you wish to taste mandioca at its best you should dig up some that has been planted only one year. I think perhaps even Mr. Root would admit that it was at least equal to potato then. It should be peeled carefully, washed, and put into boiling water with salt, and boiled for 20 to 30 minutes. As soon as it is cooked the water must be strained off and the vegetable allowed to dry. The water it is boiled in must be thrown away, as it is said to contain a strong solution of prussic acid. I do not know if this is true, but I have no wish to test it practically. Of the many other ways in which mandioca is cooked here I will give you one or two which I have tried myself.

1. Peel and wash the mandioca; cut it into pieces of a size to go easily into the meat-mincer, and grind it as fine as possible, first placing a cup or bowl under the handle end of the machine to catch the milky juice which comes out freely as the vegetable is ground. After grinding, unscrew the machine from the table without taking apart, and add the liquid still remaining in it to that in the bowl. If this is allowed to stand for a few minutes the starch (which is really *tapioca*) will be found to be precipitated with a clear yellowish water on the top. This water should be thrown off and fresh poured on, stirring up well, and again allowing the mixture to settle. In a few minutes more this water also can be thrown off, leaving the white starch, which may either be dried by evaporation in the sun, but *not* on the stove, as this turns it to a kind of gelatinous substance, or used at once as follows: To two tablespoonfuls of the wet starch add enough cold milk to mix to a thin paste, putting the remainder of one pint of milk on to boil, with a little salt, and sugar to taste. When boiling, pour in the starch and boil until it thickens, stirring all the time. When thick enough, take it off the fire and add a beaten egg. Pour into a deep pie-dish or shallow bowl and bake until done. This is very nice with fruit pies and puddings, stewed fruit, jam, or even by itself.

2. To make a tapioca pudding the starch must be quite dry and powdery. Boil the milk in a saucepan, with a little salt, and sugar to taste, and when boiling sprinkle in the starch slowly, from the hand, stirring all the time. When the tapioca is transparent take it off the fire, add one or two beaten eggs, pour all into a deep dish, and bake till nicely browned on top. Of course one can add any flavoring to either of these before baking.

Of the mandioca that has passed through the mincer, very nice fritters can be made in the same way as those of raw grated potato, adding sufficient well-beaten eggs to make them nice and light. Flour may also be added at discretion. But the principal use to which I have put this "afrecho," as it is called here, is to make bread of it.

3. Flour, owing to several causes, has been very expensive for many months, thus raising the price of bread; and as we eat a good deal of bread it

became necessary to find some material which would "reduce the cost of living." So I experimented with this afrecho, with flour in various proportions, and found it very satisfactory, if mixed in the proportion of 3 to 1—i. e., $\frac{3}{4}$ lb. of flour to $\frac{1}{4}$ lb. of mandioca. This is for baking-powder, or sour-milk-and-soda bread. I do not use yeast at all. I have also mixed maize meal with the above, using $\frac{1}{2}$ lb. flour and $\frac{1}{4}$ lb. each of the other ingredients. Proceed as in ordinary biscuit-making, and bake either in small cakes or in a loaf. The latter requires one hour to bake. Cold cooked mandioca, well mashed, can also be used to make "scones" in the same manner as cold potatoes are used. It can be ground in the mincer; but before doing so the stringy substance in the center must be removed.

In a former number of GLEANINGS you mentioned the fact of Mr. and Mrs. Terry using a gallon and a half of honey in a year, implying that this was a record. What will you say when I tell you that my husband and I (and our cat) eat *thirty* gallons of honey in one year? I mention the cat because it is ravenous for honey, eating mouthfuls of bread and honey "turn about" with my husband. It sits beside him, sharing his chair; and if he neglects to give it some as soon as he has reached that stage of the meal, it bites his hand gently, or puts out a paw to intercept the coveted sweet on its way to its master's mouth. If these methods fail it jumps on to his shoulder and proceeds to lick his hair, holding the head steady meanwhile with its claws, and this performance always results in a big piece of bread and honey being given to the spoiled animal. We have no children, so that the example does no harm, and only amuses us.

We use honey as a substitute for sugar in nearly everything, even in tea and coffee, and in jams, jellies, and marmalade, in all of which it is very satisfactory. I have also used it in frying meat and vegetables. It gives them a delicious flavor, if too much is not used. A tablespoonful is quite enough, as a rule.

I may add that I enjoy reading GLEANINGS as much as my husband does, though I have nothing at all to do with the bees; and I always read *Our Homes* and hope you will be spared to write that part for many years to come.

GERTRUDE M. BROWN.

Villarica, Paraguay, March 27.

The cassava grown in Florida is one of the easiest plants to grow I have ever gotten hold of. Along in February or March we cut the canes in pieces about as large as corn-cobs. These are bedded close together like sweet potatoes. When warm weather comes in April almost every cutting will make a nice little plant if grown in good soil. These are then planted out four feet apart each way; and with very little care they will crowd out the weeds and everything else; and they make a very fair growth on the Florida sand without any fertilizer; but of course they do better on well-worked fertile ground. On page 85 I made mention of a root as long as my leg and nearly as big; but this was the growth of two winters. We cooked some of this big root, but did not see but it was just as good as the little tubers say a foot or two long and an inch or two in diameter. We now have a vegetable-cutter for grinding the roots for poultry. It came from Sears,

Roebuck & Co., and cost only \$3.40. The chickens take it a little more readily in this shape—especially the smaller ones. The ground roots can be easily chopped up with middlings so as to make a mash.

"JABOTI CABA," A NEW SEMI-TROPICAL FRUIT FROM BRAZIL.

Last fall one of our California friends wrote me about a wonderful new fruit that they were just then introducing in California. He said the price then was pretty high, but it promised to be something of great value. Not long afterward I saw a description and photograph of the tree in an issue of the *Technical World*. Its peculiarity that distinguished it from all the rest of the trees of the world is that the fruit, instead of being borne on the end of the branches, is on the trunk and branches like a cluster of grapes. The tree grows to a height of forty feet or more, and commences to bear when about the size of a common currant bush. In order to get information at first hand I wrote to the Department of Agriculture, Washington. In response they sent me two little trees. Below is the printed matter that we copy from the label attached.

Myrciaria Cauliflora. Jaboti caba.—From Rio de Janeiro, Brazil. Collected by Dorsett, Shamel, and Popenoe. Remarkable fruit-tree 40 feet high. Popular among Brazilians. Maroon-purple, thick-skinned fruits resembling grapes with delicious, vinous, white pulp, borne on trunk, branches, and twigs in such numbers as at times almost to conceal them. May stand light frosts.

On the opposite side of the label it reads as follows:

This plant is entrusted to your care for experimental purposes. The Department wishes your assistance in determining its possible value.

You may be sure I regard these two little trees as a prize. They were sent by mail with soil attached like a potted plant. For quite a time they did not seem to make any growth, and I began to be worried about them. Finally some tiny pinkish leaves appeared on the under side of the branches, clear out of sight, and they grew pretty well until we had a prolonged drouth for something like a month. When I left my Florida garden, about May 1, I feared they would die in spite of the careful watering I was giving them. Watering is all right if applied judiciously; but it does not take the place, especially in the South, of cloudy weather and gentle rains to make things grow. You may imagine how it rejoiced my heart when I got the following letter from our friend Wesley:

Mr. Root.—We had a fine rain on the 9th of May. It rained all day and night, and since then it has

been raining; the ground is good and wet, and in fine condition.

The jaboti caba is just as pretty as can be, and just as green as grass. They are beautiful.

I've got a job with Mr. Seller in the tomato-field. The chickens, ducks, and everything are getting along finely. The cactus that you paid \$1.75 for has two buds, and the other has from four to five leaves.

Manatee, Fla., May 14.

WESLEY WELCH.

Later.—I have just received a letter, dated May 17, from my near neighbor, M. C. L. Harrison, who says, "The feterita is heading, and looks fine."

ANOTHER GREAT AND GOOD MAN GONE.

We make two clippings from the *Rural New-Yorker*, just at hand, as below:

DEATH OF PROF. VAN DEMAN.

Professor Henry E. Van Deman, well known to readers of *The Rural New-Yorker* as a frequent and valued contributor, died at his home, Washington, D. C., April 28. He was born at Concord, Ohio, his early life being spent upon his father's farm, where he gained his first knowledge of fruit-growing, both his father and grandfather being practical orchardists. Professor Van Deman excelled as a judge and student of varieties. He knew fruit as few other men do. What the opinion of a justice of the Supreme Court meant at law, a decision by Van Deman meant at a fruit show.

Later.—We clip the following from the *Nut-grower* for May in regard to Professor Van Deman:

Professor Van Deman was a native of Ohio. He served through the civil war with the volunteer troops of that state. His services as a judge in fruit exhibitions were greatly in demand, and his work along this line covered nearly every state in the Union. He served for a number of years as Chief of the Division of Pomology.

For many years past, when reading an article in regard to the progress of fruit, horticulture, etc., I have been in the habit of looking to see if I could find who the writer was, and what was his authority. Whenever I have found the name of H. E. Van Deman I have always felt sure the article was sound and reliable, and no doubt others have felt the same way. I have not been able to learn as yet what his age was when death stopped his work; but I think he must have been somewhere in the 70's.

About a year ago I read with great interest an article in the *Rural New-Yorker* from Prof. Van Deman in regard to the possibilities of the papaya. Among other things I think it stated that some specimens had borne fruit inside of a year from the time the seed was planted. I cut out the article and submitted it to my good friend Reasoner, of Oneco, Florida. He replied that there was no question but that the statements were exactly true, coming from such good authority; and I have the promise of some of the improved varieties as soon as they can be had. The trouble with the papaya

is that the seed may or may not produce fruit like the parent; and until quite recently no one has been able to disseminate the improved varieties by grafting. Professor Van Deman, however, informed us that it was then being done satisfactorily at the Government station in Miami, Fla.

The picture on page 400, May 15, was from a seedling that just *happened* to produce that sample of large, beautiful, luscious fruit.

GOOD NEWS FROM FLORIDA: "GOD'S KINGDOM COMING."

While a boy in my teens I studied geometry, and to get some practical as well as theoretical knowledge of surveying I went around several days with our county surveyor, good old Zacary Deane. I distinctly remember a little story he told me of a certain people somewhere that never seemed to know when they were whipped. He said they were so stupid that *they kept right on fighting*, and by and by licked the other party. The experience of the Anti-saloon League down in Florida brings the matter to mind. During the past winter we tried to make the great city of Tampa dry; but the big giants (the liquor party) whipped us once more, and, as the world looked at it, disastrously. But my good friend C. W. Crooke was like the people in the story—he did not seem to know he was whipped, or forgot it, for he went right on with the fight, and finally the Davis bill "won out." It is too long to give it a place here in full: but the following, clipped from a letter just received, covers the ground pretty well:

The liquor men of Florida are *stunned*.

The saloon must die September 30.

There will be left only liquor-stores selling in sealed packages.

Profits will be cut so small that 200 of the 291 saloons will die.

County-option elections will likely kill the other 91.

The Davis bill (enclosed) passed by 2 to 1 in both Houses.

The liquor lobby cannot live under the Davis bill. The Tallahassee *Democrat* says: "The cause of prohibition and good government are immensely indebted to C. W. Crooke for his effective work during the present session of the legislature."

Hon. D. C. McMullen writes: "I wish to commend the work done by the Anti-saloon League, and by yourself in particular, in passing the Davis bill, which I believe will effectually break the power of the liquor traffic forever in Florida."

Florida *Metropolis* says: "Open saloons in Florida will be abolished five months from Friday."

Tampa *Tribune* says: "If enforced, the Davis bill means state prohibition."

The *Times-Union* says: "The Prohibitionists have won out at this session. The Davis bill went through like a flash."

C. W. CROOKE,

State Superintendent Anti-saloon League.

Jacksonville, Fla., May 1.

HARRIS W. JENNINGS, SPRINGDALE, CT.—
LOOK OUT FOR HIM.

I clip the following from the *Rural New-Yorker*:

I see under the heading of Publisher's Desk of November 28 that W. K. R. is another victim of Harris W. Jennings, Springdale, Ct. I received an earnest quick order for 50 complete Langstroth hives. He seemed so honest and sincere I trusted him. Well, to this day I have not heard from him. What do you think can be done? He is the first man I ever dealt with who proved dishonest. I have learned my lesson. W. K. R. is fortunate that he lost only \$5.

H. J. G.

New York.

Nothing can be done except, perhaps, a lawsuit, but the amounts involved are not large enough for that expense. The attention of the Postoffice Department should be called to the matter.

On asking our manager if he knew anything about the man, I was informed that the A. I. Root Co. is out over one hundred dollars by this same Harris. I hope it is true there are *few* such cases among bee-keepers. And this gives me the opportunity to say that if any of our readers have lost any money by those advertising queens, bee-supplies, or anything else in our line, if they will give a brief account of the transaction, and direct it to A. I. Root personally, I will do all I can to help you get your money. If nothing can be done, the person should have his name in print so others may not be robbed of their hard earnings in a like manner.

"A CORNER IN HONEY."

On page 414 of our issue for May 15 our readers may have noticed something that looks like "a pretty big yarn." As soon as I saw it I made investigation, and called for the letter written by friend Muckle. In giving the date, 1914, his figures were so indistinct that a mistake was made. Very likely he meant to say 1913; but even if he had a whole year his record was a wonderful achievement. I have written him, and he will doubtless give us the full facts in regard to the matter.

A KIND WORD FROM THE MOTHER OF A FAMILY OF FOURTEEN.

I cannot give up that paper. Everything is good in it. I wish everything Billy Sunday says could be in every paper. I like to read it. A. I. R. does much good by his writing about how to live long and be happy while we do live. Everything he hears he writes about to help others. My family of 14 like his writing.

Wanatah, Ind.

MRS. S. P. HOWELL.

DASHEENS MAILED TO NEW ZEALAND RECEIVED IN GOOD ORDER.

Very many thanks for dasheens, which arrived in perfect order, one actually starting to grow. I wish you every success.

Coromandel, N. Z., April 7.

STEPHEN ANTHONY.

THE COAST LINE TO **MACKINAC** DETROIT CLEVELAND, BUFFALO, NIAGARA FALLS TOLEDO, PT. HURON. ALPENA. ST. IGNACE.

A LAKE TRIP FOR REST AND RECREATION.

Have a real vacation on the Great Lakes, the most enjoyable and economical outing in America. The cool lake breezes, the ever-changing scenes along the shore and the luxurious steamers operated by this Company are positive guarantees that you will enjoy every minute of the trip, and return home refreshed and glad you went.

TAKE A D. & C. BOAT WHEN YOU GO AFLOAT.

Daily service between Detroit and Cleveland and Detroit and Buffalo. From June 10th to September 10th Steamers City of Detroit III and City of Cleveland III, the "Two Giants" of the Great Lakes, operate daily service on the Buffalo Division; you can't afford to miss the pleasure of a ride on these floating palaces. **FOUR TRIPS WEEKLY** from Toledo and Detroit to Mackinac Island and Way Ports. Mackinac Island, the Historic Summer Resort of the North Country, is becoming more popular every season with the Tourists seeking quietness and repose. Excellent Hotel and Boarding House accommodations at reasonable rates. **TWO TRIPS WEEKLY BY SPECIAL STEAMER**, Cleveland to Mackinac Island; no stops enroute except at Detroit and Alpena. **DELIGHTFUL DAY TRIPS** between Detroit and Cleveland, during July and August four trips weekly. **DAILY SERVICE** June 14th to September 10th between Toledo and Put-in-Bay. **RAILROAD TICKETS AVAILABLE FOR TRANSPORTATION** on D. & C. Line Steamers between Detroit and Buffalo or Detroit and Cleveland either direction. Send two-cent stamp for illustrated pamphlet and Great Lakes Map. Address L. G. Lewis, G. P. A., Detroit, Mich. NO. 12

EDITORIALS

SO FAR as we can learn, all the best grades of comb honey have been sold, and there is a strong demand for the new crop. The market is well supplied with extracted, and producers will do well to run largely to comb honey this season.

WE call attention to four notable articles in this issue which we hope every one of our readers, especially those of the specialist class, will read and read carefully. We refer to the articles by J. E. Hand, R. F. Holtermann, E. F. Atwater, and J. A. Green. We may not in all cases agree with them, but we may be able to pick out some ideas that we can incorporate in our own beework.

WE understand that the Minnesota Legislature has cut the appropriation for the University of Minnesota by \$600,000. All departments of the University will be affected, of course; but the division of bee culture is expected to go on as originally planned, thanks to President Vincent and Dean Woods. This speaks well for the comparatively new branch, and speaks volumes for the good work done under the direction of Prof. Francis Jager.

Minnesota Beekeepers, Take Notice

THE State Inspector of Apiaries of Minnesota, Chas. D. Blaker, of Minneapolis, requests that all beekeepers communicate with him, if they have or suspect they have disease in their apiaries. Mr. Blaker fears that many do not know who the inspector is.

Honey in the Ice-box

ONE seldom hears of a dispenser of soft drinks keeping his ice cream where the hot sun can get at it, yet the opposite and equally foolish practice of refrigerating honey seems to be fairly common. An eastern provision dealer of good sense in

other lines is reported to be showing his honey in a glass case kept cold by ammonia-pipes.

There is no need to tell beekeepers that honey should be kept in a warm dry place — never in the ice-box. Not only is it an absorber of moisture, but continued cold is likely to granulate both comb and extracted. Where merchants through ignorance are found to be handling their stock in this manner a kindly and explanatory word from beekeepers should open their eyes.

A Bee's-eye View of Canadian Apiculture

THE value of Canada's work for beekeepers is about to be increased by the erection of an apicultural laboratory fitted with every requisite for research. This new building is to be located in connection with the experimental apiary at the Central Experimental Farm, Ottawa, where the problems of beekeeping are being investigated. Notice of the improvement is given in Exhibition Circular No. 18 by F. W. L. Sladen, Dominion Apiarist.

Another feature of the recent bulletin is its almost complete directions for beginning beekeeping, together with a sketch of the craft and its bearing on fruitgrowing, all within the compass of four pages. The matter is handled so concisely and yet so thoroughly that one could begin beekeeping on a small scale with no other information than that in the folder.

Langstroth on the Hive and Honey-bee in Spanish

GUSTAVO GILI, Barcelona, Spain, has just published a Spanish translation (*La Abeja y la Colmena*) of Langstroth's classic, revised by Dadant, in which the translator, M. Pons Fábregues, has carefully followed the English original, with only occasional slight changes and explanations necessary

for the better understanding of the Spanish beekeepers. M. Pons Fábregues is a well-known beekeeper of Spain, an indefatigable advocate of the modern system of beekeeping, and formerly editor of the Spanish bee-journal *El Apicultor*. He has published a number of other works on beekeeping, among them a book on the honey-bearing plants of Spain (*Flora Apícola de España*), probably the first of its kind ever published in the Spanish language.

"La Abeja y la Colmena" is attractively bound in cloth, and sells for 10 pesetas (about \$2.00), and will, no doubt, prove of great interest to Spanish and Latin American beekeepers.

A Correction

GEORGE W. YORK, in acknowledging his thanks for our editorial writeup of his political career in *GLEANINGS* for May 15, page 391, makes a couple of corrections which we deem only fair to place before our readers.

For example, we made the statement that when he became a member of the city council at Sand Point, Ida., he "initiated a movement to clean out the undesirable element of the town." He protests that he did not "initiate a movement," but he did back up the mayor.

We made the further statement that, while he "bore the Republican label, he was still a Prohibitionist at heart." This might be construed to mean that, while a third-party Prohibitionist, he sailed under Republican colors, and, therefore, was not sincere. In regard to this he says he went in with the Republicans in good faith—worked as a Republican, because that party had put prohibition in its platform. As some wet Republican newspapers might try to make capital out of this, we gladly make this correction.

Direct Advertising for the Honey-producer

ADVERTISING, like the discourse we studied in Cæsar, can be divided into two classes—direct and indirect. The latter casts bread upon the water in the hope that in due time it will turn up. Judicially inserted, carefully written advertisements in daily and weekly newspapers on streetcars and on billboards undoubtedly have a heavy pulling power, which could well be studied and utilized by the honey-producer.

The direct form of advertising sharp-shooting aims to capture the attention of the individual prospect by any one of the thousands of different means. The well-

known envelope sticker "Eat Honey" is too familiar to need description. In this case the mere suggestion calls to the mind of the recipient the thought of honey, and its own instinctive reaction is relied upon to do the rest.

The envelop enclosure is another form not too expensive, which apparently has been employed by none but the most extensive honey-distributers. A small leaf, folder, or booklet, just large enough to fill the envelope, is inserted along with the letter, and goes within the one ounce carried by Uncle Sam for two cents. If the matter is interestingly worded and attractively printed it is bound to catch the attention of the one to whom the letter is addressed.

A small blotter is something of use in every home. A neat calendar finds its place on every wall. These, if they convey the information that So-and-so has his honey on sale in every grocery store, will keep pounding it into the brain of every prospect every day he sees it. It is refreshing to receive frequent little advertisements of this nature full of good will and business-like optimism. It shows that the honey-producers are alive to the opportunities in this kind of advertising.

Co-operation in Massachusetts

MASSACHUSETTS apicultural work is all centered in one office, several phases widely different in scope coming together at one point, even though supported by many different appropriations, according to Dr. Burton N. Gates, writing in a recent number of the *Journal of Economic Entomology*.

First in the centralized organization of beekeeping as a whole are the courses of the Massachusetts Agricultural College in entomology and beekeeping. A practical museum and a beekeeping library are maintained in connection, as well as the laboratory, an apiary of fifty colonies. The work of the Entomological Experiment Station and of the extension service goes on side by side with that of the school.

The features of the college interlock with those of the inspection service as well—by no means a small part of the state work for beekeepers. A slightly different inspection policy obtains in Massachusetts. The inspectors start with well-known centers of infection and canvass every apiary, slowly widening out in circles until the limit is found. This plan seems to get results, for the beekeepers are becoming more satisfied and prosperous, and, according to the inspectors' report for 1914, many parts of the

state are approaching a disease-free condition. Dr. Gates is now looking forward to the time when the state will be relatively rid of infection altogether.

That the activities of the states for the benefit of beekeepers are tending in every case toward a centralization similar to the policy of Massachusetts is the belief of GLEANINGS. Only by concentrating efforts in this manner can each department realize the full benefit of co-operation with every other department and the complete efficiency we all look forward to in beekeeping be attained.

Death of Prominent People in the Bee-supply Line

SINCE our last issue, three people prominently connected with the bee-supply business have died. The first was Mrs. H. G. Acklin, in charge of the A. I. Root branch at San Francisco. The next was Mr. O. E. Mayfield, of the Toepperwein & Mayfield Co., San Antonio, Texas; and the last, Mr. W. T. Falconer, of the W. T. Falconer Mfg. Co., Falconer, N. Y. It is not often that three people so prominently connected with the business have passed away in so short a period.

Referring to the San Francisco office, a competent person is in charge there, and the business will continue as heretofore. The Toepperwein & Mayfield Co., when Mr. Mayfield became indisposed on account of overwork, installed a manager, and the office has been in good hands for some time back. Its policies will be continued as heretofore. The W. T. Falconer Co. is a strong organization; and even though it has lost its founder, after whom it was named, it goes without saying that there will be no change in its policies.

We will try to have a more elaborate sketch of the persons named in our next or subsequent issues. It only remains for us to say that our sympathies go out to all the friends and relatives of the parties named.

Aster Stores not necessarily bad for Wintering

WHILE this subject is, perhaps, a little out of date, yet because the discussion of it is so fresh in our minds it may be proper to call attention to some new developments just now brought to the surface which may be forgotten or overlooked.

There has been a general consensus of opinion to the effect that aster stores, while not necessarily bad, are undesirable for winter, to say the least. There has been

considerable conflict in the testimony. A careful analysis of the reports goes to show that when bees winter poorly on the aster there is usually something else mixed with it. That "something else" may be goldenrod or swamp-milkweed, or both. The combination is evidently bad. Unfortunately one or two of our yards had aster, swamp-milkweed, and goldenrod all together. One beekeeper reported that a combination of goldenrod and aster was very bad. This last year he had the combination and lost heavily. In some previous years he had only aster, and his bees wintered nicely. At one of our yards we had considerable milkweed with the aster, and the bees showed signs of dysentery as early as February.

Mr. A. C. Ames, of Peninsula, Ohio, one of our state foul-brood inspectors, was located near the aster swamp. He had neither goldenrod nor swamp-milkweed, and yet his bees wintered well.

We shall be glad to hear from any of our readers on this proposition. We will hold the reports when they come in for fall discussion. If it is shown that a combination of aster and goldenrod is bad, then the remedy is to extract before the bees go into winter quarters, and feed sugar syrup or some honey of good quality, and then use this combination of aster and goldenrod or swamp-milkweed, or both, for spring or summer feeding.

Freaks of the Weather

SOME two or three weeks ago it was getting to be very dry in and about Medina. Some days it would cloud up, and we could hear rumblings of distant thunder, but nary a drop of rain at Medina. Sometimes the dark clouds would be north of us, and at other times south; but every time we seemed to be missed. The tables are now turned. Every time there is rain anywhere along the central and eastern states, Medina gets a dose. The United States Weather Bureau maps to which we referred on p. 349 of our May 1st issue that are coming in to us every day, show some peculiar freaks of the storm-bound area. They are now showing that Medina for the last few days has been on the edge of the areas of precipitation. Sometimes we are in the center of it; but we always get it if any place does.

The weather maps show that Dame Nature has a way of equalizing. If any particular spot has been "neglected" or skipped, there come times a little later when that neglected spot will get rains if any place within 200 or 300 miles gets it at all.

We only wish we could take our subscribers and have them look over our shoulder at the U. S. weather maps, and see how the rains spread over certain areas of the United States. Apparently the rains fall in a sort of haphazard way; but a little study shows that the deficiency at one time is fully made up at another. If there is a long drouth in early spring it will be followed by a heavy precipitation in late summer or early fall. In the same way, a very cold winter is apt to be followed by a hot summer. Of course, there are exceptions to these general rules; but it is wonderful how Nature sooner or later equalizes her "showers of blessings."

In like manner an abnormal hot spell in early spring will be followed by cold and frosts. In April of this year we had two weeks of "awful hot weather." A few days after, we had cold and frosts.

Danger in Sending Old Comb by Parcel Post

WE have repeatedly advised our readers that we cannot accept shipments of old combs to be rendered into wax. We should be glad to do this were it not for the fact that our home apiary is located within a stone's throw of the railroad station, and sooner or later a box would come in bad condition—honey leaking out on the platform. If those combs came from hives containing foul brood, such leakage would be a source of very great danger to our bees.

The carelessness that some beekeepers show in sending old comb by parcel post is beyond our comprehension. Pieces of comb containing honey (and thin honey at that), and dead bees, are sometimes wrapped with a *single thickness* of paper and sent to us by parcel post for examination to see whether the comb contains foul brood. We have mentioned this matter in these columns repeatedly, but we presume these instances of what might almost be called criminal carelessness are caused by ignorance on the part of beekeepers who do not read GLEANINGS nor any other bee-journal. Nevertheless, we wish to repeat again that *we do not make examinations of suspected samples of brood*. All such should be securely packed in a wooden or tin box and sent to Dr. E. F. Phillips, in Charge of Bee Culture Investigations, Department of Agriculture, Washington, D. C. Dr. Phillips will even send government franks on request, which will save the cost of the postage.

It is because of this same danger that we cannot accept parcel-post, express, nor

freight shipments of old combs to be rendered into wax. As mentioned above, if our home apiary were not located so close it would be a different matter; but under existing circumstances the whole proposition is a dangerous one.

About a month ago we received a package of old combs by parcel post from a point so far distant that the postage on the package amounted to more than the wax was worth.

Honey-crop Conditions and Prices—Clover Prospects Good

Up to this writing, June 10, it has been rather cool in the clover districts; but there never was a time when clover looked better in most of the clover regions in the northern and central states, as there have been nice rains in most of the territory.

Clover is promising in Iowa, Minnesota, Wisconsin, Ohio, Michigan, and parts of Illinois and Indiana. Winter losses and a lack of rain, frosts and freezing, will cause a light crop in New York and Pennsylvania. From New England, reports are somewhat scarce; but from what we have received no large yield is promised. There are almost no reports from the eastern sections of the country. This would rather indicate that the beekeepers are in a state of don't know, and, therefore, are saying nothing.

Mr. J. J. Wilder, of Georgia, who is largely engaged in the business, says the reports from the South are somewhat discouraging. In the northern Blue Ridge region he says the situation is better; but further down in the Red Hills an average crop has been secured.

In northern Florida tupelo is a failure, and the yield from palmetto and other sources in the state was not large.

In Texas the prospects were good earlier in the season; but continued unfavorable weather and a severe drouth have cut down the yield, in *southern* Texas at least. A letter just received as we go to press says the crop will be thirty days late. This is generally true of the North and East also. In the famous Uvalde region there will be an almost entire failure.

In Colorado there will probably be a fair crop of honey. The shortage of snow in the mountains was made up later by falls of snow and later by rains. Prospects are also good in other alfalfa and sweet-clover producing states.

In California the situation is somewhat uncertain, and the yield from mountain sage, orange, and alfalfa is reported light, although there will probably be some fa-

vored sections. In Oregon there has been too much rain.

In Canada there were considerable winter losses, and the prospects earlier in the season were not at all flattering. It is our opinion, however, that there should be at least a light crop of clover in southern Ontario. We base this prediction on the weather maps.

If the weather warms up in the clover districts, there will be a big yield of white-clover honey in many places. It would seem that this cool weather cannot continue indefinitely. In our section of the country we never saw more white clover in *spots* than we have seen this year. The basswoods are all looking well, with plenty of buds. Indeed, we never saw our basswood grove have more buds in June than now. A well-known Michigan correspondent says there is a large basswood crop in prospect there, with clover also promising well.

Taking everything into consideration it would seem that the north-central parts of the United States, including the alfalfa districts, will yield the larger part of the honey this year. At this writing (the 12th) it looks as if there would be a good crop of honey, both comb and extracted, from white clover, alsike, and a normal yield from alfalfa in the West.

Last year there was a large crop of southern honey, and almost no market for it on account of the war. The shortness of the southern crop this year should improve the market; and as there is always a good demand for the best table honey from clover and alfalfa, prices ought to be firm, even if the yield should be large.

J. E. Hand on the Long Idea Hive and the Swarming Problem. Exploiting New Hives before they have been thoroughly Tested

In this issue Mr. Hand replies to our article on page 143 of the current volume on the subject of the Long Idea hive as used by O. O. Poppleton, of Florida. Our correspondent denies that he is a user or a supporter of the Long Idea principle as used by the Florida man. In this we stand corrected. While he does not deny that the convertible principle that he recommended on page 906 of last year is old, he goes on to show that it is good nevertheless, which fact we are quite ready to concede.

Mr. Hand is one of the oldest beekeepers in the country. He has studied this and other problems connected with the industry

very carefully, especially the one of swarming and of wintering. There are many things in his article that are true, and perhaps several others on which the veterans will take issue.

* Mr. Hand's argument would be stronger if he had not made some radical changes in hives during the last six or eight years. He first cut loose from the regular standard Langstroth hive and adopted the shallow divisible-brood-chamber principle similar to that advocated by Mr. James Heddon in 1885. This he continued to use with slight modification until five or six years ago. Then he went back to the regular Langstroth hive and frame, using the same, or, rather, a pair of them, on a double bottom-board with a mechanism to force the bees from one hive to the other to control swarming. After using the Langstroth ten-frame hive for two or three years he abandoned it for the 16-frame hive; and now he has abandoned the 16-frame hive and uses only the 14-frame hive. One who has followed all these changes will wonder if he will not yet come down to the 12-frame hive, and finally back to the 10-frame Langstroth.

Mr. Hand's argument would be stronger if he had used his big hive for more than one or two years. If one year's use of the 16-frame has convinced him that it is too large it is not impossible that next year he will decide that the 14-frame is too big. While these changes would seem to weaken his argument, we must confess that there is a thread of consistency throughout all of these various changes. First, last, and all the time he has been trying to control swarming, and has succeeded to a greater or less extent. As we understand it, he is still an advocate of his switch lever bottom, which he will use in connection with his 14-frame hive. We hope, therefore, the reader will go over his argument very carefully, because Mr. Hand shows that he understands the swarming problem; and however we may or may not like his present departure in hive construction, we must not forget that he is still clinging to much the same principles in swarm control that he has been working on for years.

In regard to the wintering problem, Mr. Hand says that winter packing is practically worthless seven months in the year, and worse than useless at other times, because the sun cannot penetrate the double packed walls. On this proposition we can not quite agree. In our queen-rearing operations we can get earlier and more continuous breeding all through the summer in double-walled packed hives than in single-walled. Often there are times when we

have cool nights and chilly days right in the midst of summer; and in our cell-building operations, at least, we find it better to use the double-walled hive throughout the year. This is not a theory with us, but a demonstrated fact. Even in a comb-honey super we find that bees will do better comb-building in a protected super, taking our weather conditions as we find them, than when there is only a single thickness of wood between the bees and the weather.

=====

Resistant Strains of Italians, and How they Make for the Reduction of European Foul Brood; Some Difficult Points Cleared up

THE Provincial Apiarist, Mr. Morley Pettitt, Guelph, Ontario, Canada, in charge of the Apicultural School and experimental work at that point, has sent out a bulletin detailing "some results of co-operative experiments on races of bees to determine their power to resist European foul brood." It seems that he sent queens from some of the best breeders of resistant strains of Italians to beekeepers throughout Ontario. He instructed each recipient "to introduce the queen to a good average colony that is affected with European foul brood. Sometimes there are colonies that seem to be immune to European foul brood for a while. Do not use these for experiment. If you have treated your bees by the shaking method, introduce the queen to a good colony that was diseased before treating."

The replies after the lapse of a year or two are exceedingly interesting and valuable. Naturally enough in one respect at least they show just what we should expect to find—that a vigorous leather-colored strain of Italians are much more resistant to the disease than the common black bees—better than Carniolans, and in most cases better than the extra yellow bees bred for color, although there is one exception where the goldens seem to be more resistant than the darker strains.

The replies in some instances are not clear on one point; and that is, whether merely introducing a queen without shaking or dequeening accomplishes a cure or not. But it would appear in most cases that the colonies were either shaken or dequeened prior to the introduction to the resistant strain of Italians. In a few cases it was very clearly shown that where blacks or hybrids continued to be used, that European foul brood came back after shaking, and continued to do so, and that the introduction of Italian blood after the last shaking finally affected a permanent cure.

It is shown also that all Italians are not proof against the disease; that a strain that is resistant in one apiary where European foul brood holds sway is not necessarily resistant in another. But this is explained by the fact that European foul brood, after it has been in an apiary or a colony for a few years loses its virulence. At the end of that time it yields more readily to treatment. It follows, then, that if an apiary has recently contracted European foul brood it will give its owner more trouble in the handling of the disease, and that when it does break out in a yard for the first time the owner should rely on all known means to hold it in check. First of all, it is of prime importance to introduce a strong vigorous strain of Italians—preferably those of the leather-colored type. The inspectors of New York have for years made this emphatic, and they ought to know. Dequeening for a certain number of days prior to the introduction of a vigorous strain may be sufficient; but it may be advisable to shake as well as requeen; and it may be necessary to shake again until the disease begins to lose some of its virulence.

Mr. Pettitt is to be commended for his enterprise in starting an inquiry that involves so large a territory, and for bringing together a mass of testimony that is so convincing on a problem on which there has been such a difference of opinion. If it is a fact that European foul brood, after four or five years, loses its virulence (and that fact seems to be now pretty well established), then it explains *why* a mild treatment in one case effects a cure while in another it seems to be entirely ineffective, and *why* there has been such a conflict in testimony. Every beekeeper, whether he has European foul brood or not, would do well to secure a copy of the above-mentioned bulletin. We presume that all Americans, at least, will have to pay, say, ten cents. Certainly every beekeeper in Canada should get a copy at once; for even if he has no European foul brood it will save him hundreds of dollars against the time when it may come among his bees. In the mean time, as a preventive means, if he has not already done so, he should get rid of his blacks and hybrids at once, and introduce in their stead a vigorous strain of Italians. European foul brood, unlike the American type, is disposed to break out again after treatment. Prevention is better than cure. While good Italian blood will not keep it out necessarily, it will help, and, what is of considerable importance, make the problem of cure much more simple if it does break out.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

MAY 24 was wet, and bees were thick on the grass in the asparagus bed—no bees on grass elsewhere. A barrel of salt had been spread on the bed. Strong proof that bees do like salt.

G. M. DOOLITTLE's discussion of winter confinement, p. 441, says nothing about difference between cellar and outdoors. With best conditions in cellar I should expect bees to stand a good bit longer confinement than outdoors.

WESLEY FOSTER says, p. 436, that opening a hive seems to aggravate drifting. Exactly. So when we set a hive on its stand we not only do not open it, but we close its big entrance down to a square inch or less. During the years since we began that we have never had a drift.

SPEAKING of making a swarm stay in a hive, p. 464, it is said, "With frames and starters of foundation they will not come out . . . and they will not come out if there is a big noise about." I wonder, now, whether either of those things have the least effect in holding a swarm.

SPEAKING of our "national crime-breeding partnership," A. I. Root says, p. 468, "We men who cast our votes are to blame—every one of us." Speak for yourself, Bro. Root. I plead not guilty. If all "we men" had voted with me in the last 40 years there wouldn't be a saloon in the land.

FIRST bloom on white and also alsike clover found May 27. But day after day it's cold and wet, seldom above 50, and bees stay close in their hives. But clover is plentiful, and if it will only honey there may be a good crop. [White clover began to come out in this locality during the last days of May; and to-day, June 4, the bees are just beginning to work on it. While clover does not seem to be abundant, yet what there is of it seems to be yielding a little earlier than usual.—Ed.]

T. J. QUAIL, p. 453, thinks I must be mistaken about bumblebees working on alfalfa. Possibly; but they looked the same as when working on red clover. I know it's the rule that alfalfa doesn't honey east of the Mississippi; but at other times I've seen enough honeybees on it to warrant the belief they were getting something. Moreover, there have been (I think in GLEANINGS) reports of bees working profitably, I think, on alfalfa in New York and Wisconsin.

[As a rule alfalfa does not yield nectar in the East; but we have had reports of its yielding in New York and Wisconsin as you say. Mr. S. D. House explains it by saying that alfalfa has to be in a locality for a considerable length of time before it yields honey.—Ed.]

E. G. CARR, p. 466, I should say that a colony with European foul brood to be "strong" enough for treatment should have bees covering five or six frames of brood, and there should be a large proportion of young bees. Your question's a fair one. Here's another just as fair. Just how many bees do we mean in general when we speak of a strong colony? I don't know; but I'll start the ball by saying not less than 50,000. [We estimate from 4500 to 5200 bees to the pound. Let us call it 5000 for the sake of an even figure, for it will be about 5000 when the bees are not filled with honey. Then 50,000 bees will mean 10 lbs. One of the biggest swarms we ever hived contained 9 lbs. of bees when placed on the scales. Your 50,000 mark, then, is not far from right, as a few bees would be left at home. For the production of extracted honey we are not sure but we should like to have the colony even stronger than that. Something however, would depend on the size and shape of the hive. An ordinary comb-honey colony probably would not have much over 35,000 bees. A ten-frame brood-nest could contain about 4 lbs. of bees. The supers might contain 3 lbs. more, or in all 35,000 bees on the basis of 5000 to the pound.—Ed.]

W. S. M'NAIR, I'm a good bit in sympathy with you about the classes of queens, p. 414. It's a perplexing question, and perhaps we ought to have a commission sit upon it. Take "select untested." If that means anything it means that he who buys simply "untested" gets something inferior. As you say, you can't tell a queen by her looks, unless there be something wrong about her, in which case all the selecting that should be done should be to select out the bad and smash their heads, and that before they're mated. Then as to testing, we're learning to put less reliance on color. Isn't the real test the performance of a queen rather than her color? And you can't know the performance of a queen till she has lived through a full season. But perhaps I'd better leave the rest for the commission to settle. [One who buys "untested queens"

Continued on page 483.

J. E. Crane

SIFTINGS

Middlebury, Vt.

We find our weak colonies wintered better in cellar than out of doors.

Bees appear to have wintered fairly well in western Vermont; clover the same.

Our bees have shown the greatest loss in wintering where they gathered the least during August, with one exception, and that was where a large number were molested by thieves.

Adam Leister's prophecies, page 326 and 327, are certainly very comforting, and we hope they will be fully realized. Last year it was very wet through April, with drouth later. Clover is very abundant hereabouts.

I quite agree with J. L. Byer as to the value of those ten-pound pail feeders, page 194. I have used them for years, and know of nothing cheaper or better. If they were made of better tin they would last longer, however.

We have found steam from a kettle for use with a steam uncapping-knife most excellent for softening and toughening the corners of one-piece sections when putting them together. They go together very much better than when water is used.

Louis H. Scholl tells us, page 222, March 15, how to keep down the swarming fever, and then as a clincher says, "After all, the secret is to begin to prevent swarming before the desire to swarm has ever awakened in the colonies. Remember that." Good advice, surely.

I can well believe what John W. Love tells us on page 324, April 15, about the yield of honey from banana blossoms. I have taken several drops from a single flower. I should think it would be a bee paradise in Central America, where so many are grown.

We have found that an excellent way to strengthen very weak colonies is to shake a lot of young bees from a strong colony, selecting a comb where they are hatching fast. Any old bees on the comb will return to the hive from which they were taken, while the baby bees will remain to cheer and strengthen the weak colony.

One of our yards of 98 colonies where they get enough honey during August to keep up brood-rearing and supply them for winter, wintered without the loss of a single colony, proving what has seemed for a long time true, that our success in wintering depends a good deal on the previous season!

The Quinby number for April 1 seemed to me a great success. I feel as though I had never fully appreciated this great man. In reading of Quinby and Langstroth the thought comes home to me anew with renewed force, how few are those who do the hard thinking for the world! It is much easier to do what some one tells us than to think for ourselves.

We fed last fall some 15,000 lbs. of sugar syrup without the addition of a drop of anything to prevent granulation. It was made two parts sugar to one of water by weight. A good deal was fed after Oct. 15, and much of it to weak colonies. I presume 4000 lbs. or more remained in the combs unsealed; yet I find very little granulated this spring—less by far than when wintered on their own stores.

I am glad to learn from GLEANINGS for March 15 that the A. I. Root Co. is going to use Mr. Poppleton's old yard at Pompano for rearing bees and queens. I see no reason why bees should not breed there freely the year round. I spent nearly a month in the yard in March and early April, and had swarms almost every day. Pollen was very abundant, and the bees bred rapidly, although little honey was coming in at that season.

Mr. T. Rayment on page 151, Feb. 15, tells us of his feeding experiments. I notice that those colonies fed on candy of sugar and honey required but little more than half as much as hives fed on honey alone, while those fed on sugar and egg ate less than half as much and had more brood. One lot he fed on pure sugar wintered well, but required a little more than when fed on pure sugar candy with honey mixed with it. Some years ago I had some colonies short of stores the latter part of winter or early spring, and bought a quantity of domino sugar and laid it on the frames and found the bees ate it without difficulty. The fact that Mr. Rayment's bees consumed the least food, and did the best when it contained

some egg with it, would go to show that some nitrogenous food is desirable in their winter food. We are looking for more light.

It seemed good to me to see Mr. O. O. Poppleton in *GLEANINGS* for Feb. 15, as I was with him for some time three years ago. What is said in praise of his hive is not overdrawn. I had the care of his yard at Pompano for some time, and I believe that, if I were going into keeping bees in the South, and extracting honey, I should adopt that style of hive in preference to any other. One of the beauties of the hive is that one can always get at the brood-nest without lifting off a heavy super right in the honey harvest.

It may be well for us who are engaged in the production of human food to remember that we are doing a strictly partnership business. We may plow, sow, and reap; we may care for our flocks and herds, our birds or bees, and we do well, for if we did not we should all starve. We should just as surely starve if our Partner did not do his part by giving the rain and warm sunshine, the fertility of the soil, and, above all, endow the plants and animals, the birds and bees, with that mysterious something we call life. It is just grand to feel that we have such a Partner to work with us, and make our efforts a success.

Mr. Henry Stewart's idea of "pumping" up potash from the subsoil by use of sweet clover is a good one, page 319, April 15. I have become very much interested in this plant, and firmly believe it is to play a very important part in the beekeeping industry of this country. Some thirty acres will be sown in this vicinity this season—not much of it, I fear, within range of my bees, however; but I am pleased to see farmers waking up to appreciate its value. I believe it has qualities that will commend it more and more to practical farmers. The valley of Lake Champlain, lying to the east of the Adirondack Mountains, is very much subject to drouth, and the strong long roots of sweet clover will help to produce good crops of forage when other shallow-rooted crops would prove a failure.

There has been a good deal of discussion during the last year or two as to the best winter nest for bees. This is well enough; but I have been more interested in the best spring nest for bees, especially the weaker colonies. It doesn't matter so much about

strong colonies, as they can get along without much difficulty; but the weaker ones—can we help them improve their nests? I notice the bees themselves hold different views on the subject. Some will start in one corner of the hive, another at one side, while another will begin in the middle of the brood-chamber, while still others will start their brood, little patches of it, at one end of the chamber in several combs. Now, how can we help them to push their brood forward most rapidly—by changing their nest? or are they the best judges of conditions or the best prophets of future results?

On page 199, March 1, Mr. E. S. Miles tells us that after keeping bees for some years he stumbled on to the greatest fact in beekeeping. He says, "This great fact is, the variation in bees." * * It took several years to convince myself that my imagination was not playing me a trick." Do we beekeepers make enough of this great fact? It is this fact that has made the keeping of fowls so profitable; that has enabled the American Merino sheep to produce nearly or quite three times the weight of wool its ancestors did seventy-five years ago; the Morgan horse to trot a mile in two minutes (or is it two minutes and half a second)? It is this fact that makes the sugar beet so profitable at the present time, and potatoes yield such superior crops of tubers; our fruit and seed catalogs so fascinating, and one colony of bees do so much better than others with the same care.

I was talking with a man a few days ago who has a cow that gave him some six hundred pounds of butter fat in one year. Now, the most interesting and important thing is that these variations are transmissible from one generation to another, and we can, if we will, greatly improve our bees and increase the pleasure and profit of keeping them.

Stray Straws

Continued from page 481.

is supposed to get a standard quality. In like manner he who buys "select untested" secures something a little above the standard so far as appearance is concerned. No one can absolutely determine in advance by her looks what a young laying queen will do. But appearance gives an indication. A full-bodied queen—that is, one well developed in size—will probably do better work in egg-laying than one whose abdomen is a little smaller. But this is not necessarily true, for there are exceptions.—ED.]

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas.

"A young queen is half the battle, both in fighting disease and in securing surplus," says P. C. Chadwick, p. 96. Is this not only true in a sense? I have seen many young queens that were not as good as older ones. Perhaps it would be better to say "young *good* queens," and better hit the mark. Nothing goes further toward good results in beekeeping than good queens.

Many times have I called attention to the mistake of extracting too close after the honey harvest, and leaving the bees short of stores during the winter months and the breeding season in the following spring. It is too risky, and many beekeepers have lost bees as a consequence. It is a too common practice that should be abandoned. The few dollars' worth of honey that may be "robbed" then would be worth more to the bees and their owner in larger returns later.

The divisible-brood-chamber hive has proven most excellent in swarm control this spring, just at a time when it seemed that every colony would cast not only one but more swarms. In the apiaries we were enabled to manipulate properly by interchanging the halves of the brood-chambers at the right time. We "knocked swarming in the head" in fine shape. Due to the preceding heavy rains, floods, and bad roads, we were not able to visit all the apiaries; and the result was that we had swarming galore at those not manipulated at the proper time. Breaking up the brood-cluster and relieving the congested condition is the secret of swarm prevention. But this must be done before the bees actually have the swarming fever already on.

The question has been asked me as to what to do with a colony that already has the swarming fever developed to such an extent, and queen-cells already built, that the mere manipulation of the hives and interchanging of combs and breaking up the brood-nest will not abate swarming. Colonies in such an advanced condition very often swarm in spite of the fact that their brood-nest and the entire hive has been torn up by manipulations seeking to alleviate the swarming fever. The best procedure, therefore, is to help them along in the matter by shaking them into a new hive on the old stand after the old hive has been moved to

one side. Only enough bees are carried with the old stock to a new location in the apiary as are necessary to care properly for the brood. Care is taken to set one comb, with one or two fine queen-cells and adhering bees, into the hive to be moved away, without shaking at all, so as not to injure the inmates in the cells. Better still, give a laying queen to the old colony and thus prevent delay in the progress of the colony.

In answer to another question by one of our readers, I wish to say that one can double the number of his colonies and have two strong ones in place of one in those localities where the honey-dew comes later in the season. Very often the early mesquite and horsemint flows fail to come in our section. If we have done our duty we have had our colonies built up to good strong ones that would have been ready for any early flow. It is often impossible to tell whether mesquite will or will not yield, so it is well to make the preparations just the same. In the event the early flows fail to come, our attention may be immediately turned toward making a good amount of increase without interference with the later flows. Increase properly made at this time will result in the new colonies being as strong as the old ones. Often the new colonies, owing to the fact that these are headed by prolific young queens, outstrip the others in surplus production. We have frequently doubled the number of colonies in some of our apiaries, and harvested twice the amount of surplus over yards that were in practically the same kind of location where we made no increase.

It may be well here to give my method of procedure in making increase in the spring when we have early honey-flows. The reader will bear in mind that we leave a super of shallow extracting-combs, more or less filled with honey, on the hives in the fall for winter stores and additional breeding room in the spring. Shortly before the early honey-flows come we slip on our comb-honey supers with full sheets of thin-super foundation, after raising the extracting-super up. This method is an excellent one to get bees started in the comb-honey supers rapidly.

More or less brood is contained in the extracting-supers at this time; and after the bees are well going on the foundation they can be removed, with the bees in them, to

Continued on page 485.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

If I were taking students to train in bee culture I would first have them read Langstroth's original work. It is a splendid foundation for the thoughts of a beginner.

Dr. Miller, in commenting on my remarks regarding chilled bees, makes a good suggestion. But the fact that we lose many bees that are not frozen but chilled and lost in the field remains unexplained.

The picture of granulated aster honey in the comb, page 329, April 1, bears very much resemblance to the product from bluecurl in California. This honey often granulates solid, even where sealed.

Louis H. Scholl recommends small stones to indicate the condition of colonies. I have used this method for years as a kind of from-day-to-day record, but am now keeping a book record for permanent information.

At this writing, May 30, the weather has reached a normal point, with the button sage nearly out of bloom in this locality, the white variety just coming in, and wild alfalfa at its best. We are getting a slow flow, the amount of which will remain uncertain for the time being.

Prospects are for a short crop in the orange and sage belts. When the button sage has its off years it matters not whether it rains by the foot or the inch. It will have its rest any way. That much has been plainly proven this season. From now on it will remain a fixed fact to me.

With an empty super, a bee-escape board, and a large wire-escape cone fit to the board instead of the little Porter bee-escapes, one can get the bees out of a super in about half the time that is required with the Porter escapes, and run very little risk of bees and honey getting too hot.

Chilled brood in colonies having swarmed during the past cold weather was not uncommon. The loss of bees from all colonies was greater than I had thought could be possible. I had colonies hived on full sheets of foundation six weeks ago (now May 28)

that drew their foundation the first week or ten days after being hived, that now have many less bees than at that time.

Dr. Miller says, page 393, May 15, that if he had my locality or bees (he wonders which it is) he would suffer no two-year-old queens except a few extra good ones. It is not the bees. I have tried stock from all over the United States, and the result is the same. I requeened most colonies last season and will make a clean sweep this year of all queens one and two years old. I cannot afford to have even ten per cent of my colonies with poor queens in the busy part of the season.

An orange-grower a few days ago said to me he was afraid the set of fruit would be small, owing to the fact that bees could not reach the bloom during the greater part of the blooming period. A few growers realize the importance of the honeybee in fruit-growing; but the majority let others do their thinking to about the extent that is done in other lines of business. In this connection I give the following clipping from the *Kansas City Star* of May 19:

SAYS "KEEP A BEE."

A. D. Wolfe, secretary of the Missouri Apicultural Society, talked at the meeting Saturday and recommended the keeping of bees in every orchard, home or commercial. Mr. Wolfe did not talk from theory, but made his speech largely a series of citations from the experiences of fruit-growers and beekeepers. Three essentials were necessary to grow fruit, he said—weather, spraying, and bees.

If a stand or two of bees is kept in each orchard the fruit will be larger, better-flavored, better-colored, more abundant, and of better keeping quality, he said. Apples and cucumbers particularly are benefited by bees, while strawberries near the hives frequently produce fair crops that would have been failures without bees. For example, he cited a fifteen-acre strawberry-field that lost practically all its first blossoms by frost. The second blossoms that came on, naturally, were weak and would have set little and poor fruit had not the bees pollinated them in seeking honey.

Beekkeeping in the Southwest

Continued from page 484.

a new location for increase. Set on a bottom-board, each given a caged queen, covered up, and the entrances closed with green weeds or grass, they will take care of themselves. After the queens have begun laying these nuclei may be strengthened by simply setting another of these supers on each one. This second lot of supers will come from colonies that had not yet begun work in the comb-honey supers sufficiently when the increase was made,

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

BEGINNING IN BEEKEEPING.

"I am about to start in beekeeping. How many colonies should I start with, and about what should be the outlay? At what season of the year would it be best to begin?"

The spring is the best time to begin beekeeping, and May or the first part of June the preferable time. Then the bees should be in a condition in all northern localities, so that "spring dwindling" will be past. If a good colony is selected on the first of June, it will be ready, usually, to take advantage of any honey harvest which will come after that. If you have on hand a surplus hive and super for each colony purchased, you will be in good condition for a successful outcome from your first venture with bees.

As to the number to start with: If you have never kept bees, nor had any schooling with some good apiarist, my advice would be to purchase not more than from two to five colonies; otherwise your increase at the start may become out of proportion to your gain in knowledge, and thus you may make a failure and become discouraged through your knowledge not keeping up with the number of colonies. One of our best beekeepers, who has accumulated quite a fortune from his sales of honey, once told me that he began with only two colonies, and that he considered that number as the best, and so advised all who appealed to him regarding the matter. This was the number of colonies I started with in 1869, so I quite agree with him in this matter. He told me that his start with bees cost him \$25. I paid out \$35 for my start; and after that I never paid out a dollar later until I had sold enough from the bees themselves to purchase those dollars.

But perhaps I should tell regarding an addition to this start which cost me nothing save my labor. Passing through a piece of woods one day in March, 1870, I saw dead bees on the snow under a tree; and on looking up I saw bees going in and out of a hole. I obtained permission to cut this tree, and in May I secured a fairly good colony, transferring the combs and bees to a hive I had made in April for them. In 1871 I set aside as many full combs of honey as I could obtain without robbing the bees I had. Then in the fall, wherever I could hear that any one was going to take up his bees, as they used to in those days by

killing them in order to get the honey, I would offer to take the bees alive and give them the honey. Of course the farmer was out what honey the bees gorged themselves with in the drumming-out process; but as most farmers are tender-hearted they liked the idea of not having to kill the bees. I got several good colonies in that way.

I remember that one farmer had two small colonies or second swarms he was going to kill with burning brimstone, and he was glad to let me have them. He offered me all the empty comb there was in addition to the bees. I put the bees from the two hives together. As all after-swarms have young and vigorous queens which are liable to breed a little later than an old queen, this colony was composed of bees of the right age for wintering to the best advantage, while the queen would be at her best the following season. The result was that this colony gave me two good swarms the next year, and I sold honey from them to the amount of \$18.76. When I jingled that money in my pocket I considered I had cleared that much, and added three colonies of bees to the apiary, besides saving the bees from brimstone torture and death.

"Do you think it profitable to save the bee-journals as they come, and pack them away? My wife does this with her magazines; but the papers I take generally go into the waste-basket."

If you do not follow your wife's example with your magazines you will show poor qualifications for a successful outcome with the bees. And, remember, you're not to allow those bee publications to lie packed away till you don't know the year dated on the first volume you have. I have nearly every issue of every bee-journal published in the United States, and most of them bound, and at my fingers' end whenever I wish to refer to them. I prize them very highly. I have had a chance several times to part with them, but have always refused. These papers have been very largely the means of making me what I am as a beekeeper to-day. They have walked with and talked to me all along down through the weeks, months, and years for a generation, giving me good advice and wholesome doctrine regarding our beloved pursuit. In fact, I have grown up with them and they with me, and to part with them would be like parting with one of the family. I am continually getting new thoughts out of them as I handle them over.

GENERAL CORRESPONDENCE

ON THE BRINK OF OWEN'S VALLEY

BY GEORGE M. HUNTINGTON.

The first illustration of my beeyard, taken Sept. 1, 1913, shows the hives before the supers were removed. The hive at the right, without any super, is empty. The season of 1913 was started with five colonies and four nuclei, and ended with ten full colonies and a crop of 17 cases of comb honey of 24 sections each.

The bees were flying about nearly every day up to Jan. 1, 1914, which was very pleasant. They had a playspell during the warm part of the day; but winter commenced that night and lasted till Feb. 1. A few days later I gave them graham flour and bran to work on as a pollen substitute. The bees had commenced to look over the alfalfa-blossoms in the haystack, hunting for pollen. I put the graham and bran in an empty hive with some pieces of glass, partly covering the top of the hive. In another hive I put a pan of water with excelsior in it with pieces of glass partly covering the top so as to give some circulation of air. The hives would become too warm if fully covered. The bees also used the top for exit. Nearly all entered at the regular hive-entrances.

Brood-rearing commenced at once. Early in April I had to take frames of brood from the strongest colonies and give some full sheets in order to hold back swarming or to check the queen's activities. Hive No. 8 had used nearly all their stores in brood-rearing. Three frames of brood were removed, and one empty comb, one comb of honey, and one frame of foundation given to replace the frames of brood. Then a super with twelve cull sections of honey was placed on the hive. On May 5 two more frames of brood were taken away, and two frames of full sheets given.

The super with the twelve sections was removed on May 12, nicely filled with fruit-bloom honey. Another super was placed on the hive with four bait sections. My record shows that this full super was taken June 1 with wild-buckwheat honey and some sections from mixed sources. This stand of bees, No. 8, can be identified in the four pictures of Nov. 1st as the one with twelve supers, showing how it would appear with the season's crop all on, 335 filled sections and one bait section with comb fully drawn but no honey in it. Out of the 335 sections

G. M. Huntington's apiary, looking across Owen's Valley toward the White Mountains.

Twelve supers containing 335 filled sections, the season's harvest from one hive.

there were thirteen that would grade as culls an account of not being fully capped over. All of the rest were No. 1 sections. Some were a pound, and nearly all above 13 oz. net.

In one of the pictures I am standing next to No. 8 for a comparison of heights, my height being 5 feet 10 inches. Each hive requires a stone on the cover to keep it from making journeys. As you will see, nature has provided lavishly of these necessary articles, and there are spare stones for more hives, but no places to locate any more hives.

The next hive with comb-honey supers to the left is my first swarm of the season, cast May 5. It produced 196 sections. The next to the left of it, in front of the honey-house, produced 103 sections and 101 lbs. in brood-frames filled with full sheets. The second swarm was cast May 6. In the distance are the Sierra Nevada Mountains. My other increase (three colonies), produced 72 sections, 71 sections, and 73 lbs. in ten new brood-frames. The 1914 season's production from the ten stands as shown in the Sept. 1st, '13, picture was five colonies increase, or 50 per cent, and 81½ 24-section cases of comb honey and 30 new brood-combs filled with honey. These brood-combs are for spare stores to replace some old combs which I may wish to cull out in the spring if any stretched cells or drone-cells

are found. Every inch of my brood-combs must be working, and contain worker-cells.

The view across Owen's Valley shows in the foreground the trees where swarms cluster to be hived. I climb down instead of up, as is the usual manner of getting to the clusters—down on my knees. Seen in the distance are the White Mountains, elevation over 12,000 ft. In another view (cover picture) the Sierra Nevadas rise in the distance with snow-covered peaks over 14,000 ft. in elevation.

The nearest alfalfa in this location is 1¾ miles away, and not more than 200 acres within a two-mile circle, all on the side toward the White Mountains. The Owen's River Valley is here about 14 miles wide. In some of these pictures two hives are shown that were moved in at the close of the season from a neighboring apiary.

I am inclined to credit my season's success to a correspondence course in beekeeping which I finished about two years ago.

The diploma I received, and the crop produced, have promoted me from the A B C class to a fairly good start in the Division of Agricultural Education Correspondence Course No. 15 of the University of California. This calls for some brushing up of the botany on which I had never done any reading. But I hope to live through it, even if do have to make sketches of bees' tongues.

Bishop, Cal.

EFFICIENCY OF THE FOURTEEN-FRAME HIVE

BY J. E. HEND

On page 148 the editor accuses me of using the Long Idea hive, and quotes Mr. Poppleton as saying that the convertible principle of wintering bees is very old—a statement which the editor seems pleased to emphasize. He might have added that it is also very efficient, a fact that I am especially pleased to emphasize. It matters little whether the convertible hive is new or old, so long as it is thoroughly competent.

Profits in beekeeping are not governed by the amount of honey produced, but rather by the cost of production. Proper beehive architecture is virtually a matter of decreased cost of honey production by economical methods. The value of a hive is measured by its solution of problems inseparably associated with honey production—namely, the breeding, the swarming, and the wintering problems. A hive that solves these problems is thoroughly competent. Efficiency consists of fitting the hive to the principle, regardless of size, instead of trying to cram a great big principle into a little hive. The idea of recommending a hive simply because one man can handle it easily is like recommending a horse that one man can hold by the traces. The twelve-frame hive is uneconomical for reasons just given. "So near, and yet so far."

THE BREEDING PROBLEM.

Since horizontal expansion of brood-chambers and vertical expansion of supers is generally recognized as the correct principle, a competent breeding hive must be large enough to accommodate prolific queens. It has been ascertained that 14 Langstroth frames are the limit of expansion consistent with queen fertility;

hence 14 frames is the limit of practical expansion, and 20 x 24 inches the dimensions of a competent breeding hive.

THE SWARMING PROBLEM.

While large hives do not prevent swarming, they are important factors. Swarming is not a premeditated act, but the fulfillment of a natural impulse in which restricted breeding room or diminished queen fecundity, or both, are the active forces. Unlimited breeding room and undiminished queen fecundity means little swarming. Requeen before the zenith of fertility merges into broodiness, for broodiness begets supersedure cells; and supersedure cells beget swarming, on conditions. Broodiness in queens, as in hens, is a period of temporary exhaustion of fecundity during which the ovaries are speedily developing another batch of eggs. During this period of broodiness which varies in duration with

More stones, and a substation of the Southern Sierra Power Co.

different queens, the mother-instinct predominates, and the queen will lay eggs in queen-cells, and at no other time. Hence cells built with a laying queen present are always supersedure cells resulting in supersedure of swarming according to the condition of the queen, colony, and honey-flow.

When we understand bee nature and the laws that govern the swarming impulse we can prevent it intelligently and economically by the following method: At the beginning of clover bloom make all colonies strong by uniting and equalizing, and take two combs covered with bees, including the queen, from each fourteen-frame hive, substituting empty combs and a ripe queen-cell in a cell-protector. The two combs and queen are placed in a thin-walled wintering-chamber for increase at the close of the basswood harvest.

THE INCREASE PROBLEM.

Ordinary methods of forming increase are objectionable on account of the labor involved in building up nuclei by stimulative feeding and by peddling combs of brood. Hence a more rapid and economical method is imperative when much increase is desired. A competent hive contains all the material for 100 per cent increase in full-sized colonies simply by utilizing extra combs and bees on hand at the close of the harvest. Here is the method: At the close of the basswood harvest, after the honey crop is secured, the hives are literally overflowing with bees and brood, and this is the time to form increase economically. Cage the queens in the nuclei mentioned under swarming, and take six combs containing brood covered with bees from each fourteen-frame hive, placing them in each nucleus hive which now holds 8 combs, and the parent colony will also have 8 combs, and both have laying queens. I regard 8 frames as a practical wintering colony, and give no more except in case of an unusual fall honey-flow. In this way a competent hive solves the increase problem with the utmost economy, securing 100 per cent increase and a full crop of surplus honey while paving the way for an economical solution of the wintering problem.

THE WINTERING PROBLEM.

Ordinary methods of outdoor wintering consist of enclosing hives in winter cases with suitable packing between. Winter cases are idle seven months of the year. The thick inner walls and thin outer walls are poor protection. In a northern winter sunny days are scarce, and chilling winds are the general rule. It is advisable to make the outer case of thick lumber and

the inner case of thin material that the heat may penetrate the packing and maintain an even temperature in the inner chamber, which should be contracted to the fewest combs required to hold sufficient stores. The convertible principle makes a competent hive serve as a winter case providing perfect winter protection with no extra equipment except a thin-walled inner chamber 12 inches wide inside and 12 inches deep, made from old packing-boxes. These are used in summer for nuclei, increase, etc., and are not idle capital. Since half the colonies are already in their wintering chambers these are placed on the floor inside a regular fourteen-frame hive lengthwise, and the frames at right angles to their accustomed position, and at right angles with the entrance which is at the end. This creates a space of $2\frac{1}{2}$ inches surrounding the inner chamber except the front end, which is pushed up tight against the hive with a heavy sheet of insulating paper between. The extra depth of the inner chamber (12 inches) provides a space of $2\frac{1}{2}$ inches under the combs, while a full-sized upper story holds 8 inches of packing on top of the inner chamber. The whole is kept snug and dry by a three-inch water-proof cover. The parent colonies are treated in like manner, and all are snug and cozy in their winter nests at a cost of 25 cents for equipment as useful in summer as in winter.

With an outer case $\frac{7}{8}$ inch thick, and an inner chamber $\frac{1}{2}$ inch thick protected with heat-retaining packing, the temperature on both sides of the inner walls will be practically the same, especially with extreme contraction of the winter nest, which is the key to successful outdoor wintering. Moisture will not condense, but is conducted out through the entrance after every particle of heat is utilized to maintain a normal winter temperature without extra consumption of food. Heat is generated by the oxidation of food and vital energy expended in muscular exercise. To allow heat to escape from the winter nest by upward ventilation through porous packing, erroneously called an "absorbent," wastes bee energy. Sealed covers on the inner chambers under the packing preserve the heat. This principle is thoroughly scientific, and requires extreme contraction in a well-protected hive with an entrance $\frac{3}{8} \times 10$ or 12 inches to conduct away humidity by diffusion with the circulation of air in the deep air-chamber under the combs. I began with a sixteen-frame brood-chamber, but soon discovered that while bees, if crowded for room, will adapt their work to existing hive proportions, they have a decided preference

FIG. 1.—First position in reversing the comb. This commences a continuous sweep of the frame, which never allows the comb to be held flat, unsupported by the frame.

for vertical expansion beyond a certain limit of horizontal expansion. The outside combs of the brood-chamber were entirely neglected. I moved filled combs to the outside, an inconvenient manipulation with a brood-chamber under a heavy super. Hence I reduced the size of brood-chambers to 14 frames which I now regard as the limit of expansion consistent with queen fertility, and the limit of contraction for the solution of problems.

Viewing it in this way the Long Idea principle cannot well be combined with the supering method, and exclusive horizontal expansion is contrary to bee nature; hence excessive frame manipulating is required in moving filled combs to the outside, substituting empties in the center to insure good

work and prevent swarming; for bees will swarm from a 24-frame Long Idea hive with one-fourth of the combs empty.

The solution of problems is possible only with correct principles of beehive architecture consisting solely of 8 inches of horizontal expansion added to an ordinary ten-frame hive. Eight inches of horizontal expansion, at a trifling cost, changes a practical nonentity to a degree of efficiency hitherto unrecorded in beehive methods.

The method of increase outlined in the foregoing demonstration is for a clover and basswood location. In locations where the main harvest comes in August and September it is advisable to form increase in June by the method given.

Birmingham, Ohio.

HOW NOT TO DO AND HOW TO DO.—III

Beginning in Beekeeping; Handling Combs

BY R. F. HOLTERMANN

Perhaps there is no operation in beekeeping which is conducted in such a diversity of ways as the fundamental manipulation of the hive—viz., the handling of the combs, and there is no work in connection with beekeeping which has to be done more frequently. The most of our labor is done in order to secure fruit from it, and that being the case we do not wish to expend any unnecessary exertion upon it.

When a piece of work is not done very often, we are apt to think the expenditure

of the minimum of energy is a matter of no importance; but let me say it is of very great importance. Individual acts put together become habits; habits in time become principles, be they right or wrong; and the result is they become the basis of action in our lives. If my training has been neglected I have to correct that training; and if I cannot do it in my own strength I can draw on an exhaustless store outside of myself.

It may justly be said we are born with

certain tendencies. That is undoubtedly true; but much can be done as to fitness, before the world's eyes, by training in the right direction. One must do work constantly in the right way until it becomes almost an involuntary act with him.

Fig. 1 illustrates my favorite position when examining a hive. The cover is taken for a seat. There is a cover for every hive. It should be convenient, and it should be just the right height. Each hive should have a quilt or honey-board under the cover. I believe that, in the United States, this is quite often not the case.

There is one other position which I sometimes assume, but only when I am very tired—"played out;" but, on account of pressure of work, I cannot afford to stop working; that position is to get down on my knees by the side of the hive; but that is not a good position under normal conditions.

FIG. 2.—Raise the end in the left hand, bringing the frame to a vertical position.

With the elbows resting on the knees, as in Fig. 1, the weight of the comb is supported by the knees, and relieves the arms during examination. After the one side of the comb has been examined (note the top-bar on the upper side), to examine the other side I have a regular circling and sweeping movement of the comb to bring to view the other side. In no case is the comb to be held flat as in Fig. 6.

In hot weather a heavy comb will break out when so held, even if it is fairly well wired. If the comb is not wired and not well fastened at the bottom and at the ends, it is almost sure to break out. If the reader will take a comb in his hand, make a circling motion, following 2, 3, 4, and 5, he will get my method of turning a comb. In Fig. 5 he will see the comb with the top-bar at the bottom. When possible the sun should be behind the one manipulating the hive, allowing its rays to strike

FIG. 3.—Twirl the comb with the top-bar as a pivot, the comb being supported by the end-bar.

into the cell where eggs are looked for. To find the eggs I sometimes have to step out from the shade of a tree and allow the sunlight to shine into the comb-cells. The same advice holds good in looking for the scale on the lower side of the cell. The light should then be allowed to shine on the lower side wall of the cells in the comb.

If the work is always done in that way a beekeeper is not likely to forget the proper way to hold a comb and hold it as in Fig. 6.

Make a system of handling combs and it will become a habit which will not require much study to maintain. But as a rule the

people who forget the most, dislike system, although they need it the most. They would

prevent much discomfort to people connected with them.

Brantford, Canada.

FIG. 4.—As the other side comes into view, lower the left hand. The comb rests on the top-bar.

NET-WEIGHT LAW A STEP IN ADVANCE; CURRENT COLORADO COMMENTS

BY J. A. GREEN

The law requiring the marking of net weight on sections of honey seems to be causing a great deal of trouble and much apprehension among some beekeepers. While there may be some undesirable features about the law, it is in the main a very good one, and requires practically nothing more than many beekeepers have been doing for years. It will tend to enforce better methods of honey production as well as grading, both of which have been very much needed. The one who has carefully followed the grading rules established by the Colorado Honey-producers' Association will find it easy to go the step further required by the new law. The apiarist must adopt methods that will result in sections as uniform in weight as possible, and then assort them according to weight so that there will be little variation in weight between the sections in any case. It then becomes an easy matter to stamp every section of that case with a minimum weight that will fairly represent what the purchaser receives.

I am glad to see on page 922, Dec. 1,

1914, that R. A. Burnett is now ready to recommend grading by individual weights. When I advocated this in GLEANINGS some years ago Mr. Burnett was inclined to poke fun at me for going to the trouble of "weighing the honey for the retailer," but I felt well repaid for it in the higher price I was getting for my honey. "All things come to him who waits," and it is pleasant to see one after another of the things we old timers worked for in the past come into use now, even if we do not get the credit for it.

Before I leave this subject I wish to say again that it is a great pity that the majority of honey-producers still cling to the 1 $\frac{7}{8}$ -width section. Many years of experience in comb-honey production, much of this time using both sizes of section, have convinced me that the narrower section, seven to the foot or thereabout, will give more honey, nicer honey, and more uniform weights than the wider section which was adopted and continued in use merely because it happened to fit the hives and su-

pers then used, with a little less complication than a section that suited the requirements of the bee better.

The net-weight law should give the finish to the old idea that the regular $1\frac{7}{8}$ section is a "pound section," and there is really no other reason for continuing it except the inertia of beekeepers, and especially of supply-dealers, and the slight expense of changing the old supers to accommodate a narrower section.

I honestly believe that the use of the $1\frac{7}{8}$ section, instead of one better adapted to the nature of the bee, has cost the beekeepers of this country thousands of dollars annually. I wish I could prevail on them to test the matter themselves on a scale large enough and for a time long enough really to know for themselves.

THE ARMY-WORM AND CLOVER.

The statement on page 745, October 1, 1914, that the army-worm does not eat the clovers, is certainly wrong in this locality—at least so far as sweet clover is concerned. The army-worm was not very bad here last summer, but it was here in sufficient numbers to give a good idea as to its habits. One thing that impressed itself on me was

FIG. 6.—In no case is the frame to be held flat, the comb left unsupported, as in this illustration.

that it evidently preferred sweet clover to alfalfa, or, in fact, almost anything else. They could be found in considerable numbers on the sweet clover along the irrigation ditches bordering the alfalfa-fields before they attacked the alfalfa at all; and

FIG. 5.—The comb is supported by the top-bar at the bottom. It exposes for inspection the side opposite to the one in view in Fig. 4.

I believe that, in many cases at least, they never entered the alfalfa-fields at all at such points.

YELLOW SWEET CLOVER.

Does any one really know anything as to the value of yellow sweet clover as a honey-plant? I should like to know. I used to think it must be very valuable, but for several years I had three or four acres of yellow sweet clover close by an apiary of about 50 to 75 colonies. They worked on it most vigorously. It sounded like a swarm of bees anywhere between the apiary and the clover-field, and there were few other bees in the vicinity. Yet there was very little show of honey in the hives. Perhaps they used it all in brood-rearing, but it seemed to me that the same acreage of white sweet clover, later in the season, would have shown more surplus in the supers.

FOUNDATION SPLINTS.

If Jacob Alpaugh, after sawing his thin boards as described on page 940, 1914, will dip them into hot beeswax, pressing them closely together until it is cold, he will find it much better than the glue he uses. This is the plan I have always used, and which I described in GLEANINGS several years ago. I dipped the thin boards into the hot wax separately, piled them up, and put them into a press before the wax got cold. As soon as the wax cooled, this block of boards could be sawed up just as though it were a solid piece, yet the splints would separate as soon as they were put into hot wax. Mr. Alpaugh's description of the

way he inserts splints makes one wonder how long it takes him to prepare a hundred or a thousand frames. I do not use splints any more. One of my greatest objections to their use was the time it took, even when they were put in in the ordinary way. I consider that the plan of painting the foundation with hot wax, after it has been put into wired frames, gives better results with less labor.

DOES BOILING ALWAYS STERILIZE?

In addition to what I said on page 975, Dec. 15, 1914, I should like to add a warning against relying too much in high altitudes on boiling to kill foul-brood bacteria.

One thing that must be remembered, when it comes to the question of sterilization by boiling, is that liquids boil at a lower temperature in a high altitude, such as we have in the greater part of Colorado. Water boils, for instance, at 212 degrees at sea level. Here it boils at about 202 degrees, or eight degrees lower. In much of the

beekeeping territory of Colorado, water boils at 200 degrees or lower. So the statement that boiling for a short time kills the germs of foul brood at Washington, D. C., might be perfectly true, and yet dangerously deceptive to the beekeeper of the mountain valleys of Colorado. Furthermore, bacterial life exists in two forms, and in the form of spores it will withstand a much higher temperature than in the ordinary form. I have seen the statement lately that bacilli that, in the ordinary form, were killed by a short boiling, had in the form of spores remained alive after being subjected to the temperature of boiling water for sixteen hours.

I have seen a great deal of foul brood, both in my own experience and in the capacity of bee inspector; and as a result of that experience I firmly believe that, for the average beekeeper, destruction by fire is not only the safest but the cheapest method of cure.

Grand Junction, Coló.

NOTES FROM GERMANY

A Beekeepers' Association of Old Standing

BY J. A. HEBERLE, B. S.

In the year 1850, prominent beekeepers of Germany and Austria formed an organization to promote practical and theoretical knowledge of beekeeping. The organization called itself *Wanderversammlung*, and the meetings which are held annually are known by the same name. In 1885 Hungary joined the association.

The place where the session (which lasts several days) is held is selected at least one year ahead. The countries take a turn about—one year in Germany, the next in Austria or Hungary. Usually several invitations are presented. The selection is decided by vote. The inviting local club arranges for the time of meeting, and for an exposition, and provides for social entertainment and an excursion to some place of interest. The exposition includes bees, honey, wax, and products thereof; hives, tools and appliances, books, bee journals, etc. A considerable amount in premiums is distributed among the exhibitors according to the recommendation of the judges appointed for this purpose.

The most interesting part of these meetings are the numerous lectures by eminent men of science, and practical beekeepers, with the resulting discussions. This part of the program is arranged by the executive

of the *Wanderversammlung*. For admittance to the exposition a small fee is charged to outsiders. These receipts and a contribution from the government usually cover all the expenses.

Each country has its own officials which arrange and conduct the meeting when held in their country. The officers—a president, a vice-president, a secretary, and four counselors are elected for a term of six years by a majority of the members present from each country. They may be re-elected. Any respectable beekeeper, by paying a fee of 75 cts. to one dollar becomes a member for that meeting—is admitted free to all the lectures, to the exposition, the entertainments, etc., and has the right to vote.

With few exceptions these meetings have been held every year. In June, 1854, the meeting that was to be held in Koln in August was, owing to the warlike disposition of Europe, postponed to 1855. In July, 1859, on account of war disturbances, the meeting was postponed till 1860. In June, 1866, the president announced that, "owing to the seriousness of the political situation which prevails everywhere, the meeting will not be held this year."

In 1913 the meet was held at Berlin. The exposition wound up with a deficit of

The apiary is exposed to the sweep of the winds.

about 10,000 marks. The expenditure was unusually heavy, and the patronage fell short of expectation. As the invitation of Berlin for 1913 was presented at Konstanz in 1911, some one warned against holding the meeting at so large a city. The numerous attractions of all kinds that are constantly presented to the public make these city folks indifferent to an exposition of bees, its products, etc., and predicted a lack of interest. The same voice, of course, did not fail to say, after the festivities were over, "I told you so." The fact is, all the expositions in connection with these meetings in smaller cities and large towns came out about even, or had a small surplus, while at Berlin, with its millions of people, the exposition was financially a failure. The exposition itself was creditable in every part—that was the unanimous judgment. The expenses may have been heavy, but it would seem that, by properly advertising it, patronage should not have failed. Why should such an exposition not arouse the interest of the city folks? I do not think

that this one failure should prevent the *Wanderversammlung* at a future time from accepting an invitation from a large city as some have predicted.

In 1914 the perigrinating beekeepers assembled at Pressburg-Poszony, Hungary. It is a town of 80,000 inhabitants, an hour's ride on the express from Vienna. The reception of the beekeepers from afar, and the exposition, received the praise of all the visiting brotherhood of beekeepers. Hungary has better bee-pasture than Germany, and is noted for its water-white honey from the acacia (locust-tree). The exposition was opened July 26, and was to be closed on the 30th, but on account of the outbreak of war it had to be closed the next day. The visiting beekeepers, many from considerable distances, Germany and Austria, were advised to leave on the morning of the 28th. After that time the trains in Austria were for some time reserved for the war department.

Kempton, Bavaria, Germany.

AIR DRAINAGE IN THE APIARY

BY E. F. ATWATER

For a long time the writer considered natural shelter to be a very desirable point in locating an apiary. For several years we had a yard consisting of 100 to 150 colonies, located where it was sheltered

from prevailing winds by an orchard on the west and a railroad embankment, a few feet high, at the north. Previously the same apiary had been located some rods to the south, giving still better shelter, as hog-

houses and haystacks gave considerable protection from the south. The ground was level, with a slight rise to the north.

We seldom lost many colonies outright in this location, in wintering, but usually found it impossible to bring them up to the standard of the other yards with less shelter, at the opening of the flow, even though they were allowed more stores.

A discouraging feature each spring would be finding fully half of the bees of most colonies dead on the bottom-boards and part way up between the combs. This experience and others resulted in our theory of the necessity of sufficient air drainage for the best results in wintering and spring breeding.

Finally we moved this apiary. The only available location near was on a north slope, upon quite steep ground. Here the bees winter and breed up better, though exposed to the full blast of the northwest winter winds. We find that a south slope, not too steep, gives still better results; but we can

not get as good results on level ground with natural shelter. The only reason that we can assign is the lack of air drainage.

This view was corroborated at the Idaho convention about a year ago, when Mr. Nelson, of Oregon, gave his experience on the same lines, saying that his best wintering and breeding yard was exposed to the full rigors of the winds.

The illustration will give some idea of the present location of the yard where these results have been so apparent. This apiary is on the north slope of the "Mesa," or bench, while high above it, a little to the south, runs the canal supplying water to the valley lands.

The sage brush in the foreground furnishes fair smoker fuel, though it burns out quickly.

This yard is run for extracted honey, and contains mostly Italian bees of a fine strain.

Meridian, Idaho.

WHAT TO DO WITH WEAK COLONIES IN THE SPRING

BY T. DWIGHT WHITMAN

The question of how best to dispose of weak colonies in the spring is sometimes hard to answer. If they are united, in a short time you have one weak colony and nothing gained. A better way is to put a thin partition in a ten-frame body not over a quarter of an inch thick, so that the body is divided into two bee-tight compartments. Then arrange the bottom-board in the same way (see Fig. 1), making the entrances at the outside corners of the body. Place the frames occupied by the queens on each side of the division-board, any frames with brood in them coming next, and the frames with honey in them next until the body is filled; then your cover cloth and a tight cover over all. Leave them thus until they begin to get a little crowded for room. Put on a queen-excluding board, and on that a full-depth super body or super of sections.

You will be surprised to see how quickly the double hive will build up both before and after the extra body is put on, and how much heat is to be felt if you put your hand on one side of the thin partition when the bees are on the other side of it.

The two colonies do not fight in the upper body above the queen-excluder, but agree peaceably, and this upper body makes an ideal place to put a small queen-nursery (see Fig. 2).

My nursery, which shows in Fig. 1, in

front of the bottom-board, is made from a piece of 1½-inch by 2¾-inch lumber with inch holes bored from the top as shown, to meet holes of the same size bored through the piece, the sides being protected with screen wire and the top with a tin slide. The slide is shown partly drawn out in Fig.

FIG. 1.—Double hive and bottom-board. In front of the latter is the queen-nursery.

1, in nursery at bottom of the queen-excluding board.

The holes bored from the top, stop on reaching the holes bored from the sides, leaving the bottom of the nursery of wood smooth on the bottom. This makes a good place to put artificial cells; or if the bees insist on building comb on the bottom of the nursery, as they sometimes do, it is easily scraped off with a hive-tool.

As the bees above the queen-excluder are practically queenless, they will readily accept a virgin queen if confined for a short time in a Miller cage as shown in Fig. 3. While they would feed and care for the virgin queens in the nursery, I found that it was not practicable to make use of a small door to the different cells in the nursery to allow the virgin queen to come out

FIG. 2.—Queen-nursery for use in full-depth super above a queen-excluder on a double hive.

FIG. 3.—Queen in Miller cage ready for introduction.

after she was hatched. The bees would always kill her. But I could form a nucleus of one or more frames of bees from the upper body, and by wetting them give them a virgin queen from the nursery. They would accept her at once.

As the double hive below supplied a strong force of bees to the upper body, they would draw out full frames of foundation very quickly, and this was a great convenience if I was raising a few queens for myself.

The bees will work together peaceably above the queen-excluder all summer, but must be separated before winter by extending the thin division-board to the cover or otherwise, or they will kill one of the queens.

Tacoma, Wash.

PROPOLIS POISONING; ITS SYMPTOMS AND CURE

BY C. R. PARKS

Not heeding the oft-repeated advice to start with a few colonies of bees and work gradually into the business, Mr. De Loss Corey and I purchased slightly more than 300 colonies, and plunged into the game.

The first and most serious obstacle encountered by the writer was propolis poisoning. Never having heard of it, the poison was supposed to have come from ivy or poison oak; but salt water and soda (the

An apiary at Luxor, Egypt. Photographed by W. Percy Chase, Brookline, Mass.

remedy for these) would not cure it. Physicians were consulted, but they gave little relief.

I soon discovered that working with supers or old hives renewed or increased the poison; and on making inquiry I learned that propolis poisons some people. My eyes swelled almost shut, and the effect of the poison spread over a considerable portion of my body. The suffering was intense.

One doctor advised a mild solution of carbolic acid and water, which gave relief; and by increasing the proportion of the acid it would cure it, but often left the skin in an inflamed condition. I wrote to the bee journals and beemen whom I knew, but none knew of a remedy. Some of the propolis was sent to the Department of Agriculture for examination, but they reported no poison could be found.

That first season we averaged about \$10 per colony. It was an unusual season. The next season a doctor advised me to try sugar of lead and tincture of opium for the poisoning. This I did. Two or three and sometimes four applications of this will cure it. I use it in about the following proportions: One teaspoonful of sugar of lead; one tablespoonful tincture of opium; about six ounces of water. Shake thoroughly, and apply with a small cloth or sponge.

If too strong it will smart and burn; if too weak, more applications are required to cure.

At the end of the third season the writer sold out, Mr. Corey continuing in the business. We were living in the Plateau Valley, Colorado. Part of that winter and the following summer were spent in California. While there I applied propolis to my arm, and learned that it would poison me in California as in Colorado. However, the lure of the bee was too strong, and I returned to Colorado and from there removed to my present location in Utah, where I engaged in the production of extracted honey. In producing extracted honey I am not poisoned as much nor as severely as when producing comb honey.

Since coming here I have secured several valuable recipes for the relief of propolis poisoning.

The one I prize most highly is a powder—camphor, half a drachm; oxide of zinc, one ounce; starch, one ounce. Dust the affected parts well, and, unless it is a severe case, relief and a cure will be the result. This powder can be used about the eyes and other tender portions of the body without irritation; but it is well not to get it into the eye.

A Sicilian apiary, Taormina. Photographed by Mr. Chase.

Covering the hands and wrists with soap before working in propolis aids in preventing poisoning, and assists in removing propolis from the hands.

The following recipes are recommended:

1. Borax, two drachms; glycerine, two ounces; water, two ounces. Mix, and apply to inflamed skin.

2. Oxide of zinc, two drachms; lead wa-

ter, one drachm; wine of opium, 4 drachms; rose water, four ounces.

3. Baume analgesique bengue will give relief, but will smart the eyes or other tender portions of the body. It can be secured from chemists.

Bear in mind that most of these prescriptions are poisons, and should be kept out of the reach of children.

Hayden, Utah.

THE USE OF WIRE SCREENS AS A SEPARATOR IN THE ALEXANDER METHOD FOR WEAK COLONIES

BY JOSEPH J. ANDERSON

The Alexander method of building up weak colonies requires placing the weak colony over a strong one with a queen-excluder between. My experience has been that the bees from the strong colony below will frequently kill the queen of the weaker colony above, and so the practice of putting a sheet of wire screen over the excluder was resorted to, removing it at night after the bees were all settled and quiet with very satisfactory results. To save the trouble of going to the bees at night—quite a chore where one has outyards at some distance—

I thought it would work all right to place a sheet of newspaper over the excluder, leaving the bees to eat their way through the paper and enter the upper hive-body at their leisure. Two seasons of this procedure have resulted in a loss of fully seventy-five per cent of the queens of the weak colonies. The paper idea won't do. It is unnecessary here to discuss the reasons.

On May 6 of this year I treated weak colonies at the home yard, some of them with not more than a few square inches of brood. As I went through the bees I mark-

ed all the weak ones, then an equal number of strong ones. On the latter I placed queen-excluders, and over these excluders wire screen. Then, on these strong colonies so prepared, the weak ones were placed. In the evening, when the bees were settled, I removed the screens. This is done with a quick jerk.

May 14 an inspection showed that every one of these formerly weak colonies had from three to six combs well filled with brood.

This method of building up weak colonies I call *Alexandering*. Uniform success will attend the carrying-out of the plan, as outlined above, at least in our locality. But don't fool with paper or any other modifications.

The weak colony so treated should be left on the strong one for three weeks or more; and if the queen is any good your hive will be filled from side to side with brood.

One of the bodies now set on a new stand, using your judgment as to which. Your weak stock has now become a rousing colony with force enough to render a good accounting of itself; whereas, if let alone it would have died out entirely or taken the whole season to build up strong enough for winter.

Making the sheet of wire screen several

The keeper of the apiary at Taormina, Sicily. Photographed by Mr. Chase.

inches longer than the hive, and cutting it in two pieces with the ends overlapping in the middle facilitates removing the screen, as half can be jerked out in front and half behind without disturbing the relative position of the hives.

Salem, Idaho.

THE EFFECT OF STORES UPON BEES

BY R. F. HOLTERMANN

Yesterday and to-day, although the weather is not very warm, we have been doing some needed work in two of the apiaries. In each we noticed a good deal of fresh spotting upon the black covers of the winter cases. I was much impressed with the condition, and I believe it is unusual for this time of the year. The spots were

the excrement voided by the bees while on the wing, and it was almost solid, but strung out in lines. I attribute it, first, to the bad stores collected by the bees last summer, and which they are consuming now; next, to their confinement for unusually long intervals.

We have had three heavy frosts this

week. Those Monday and Tuesday nights were so severe that ice formed on a tub of water by the pump at our house. Another on Wednesday evening was not so severe. We also had two frosts last week. I do not know whether clover has been injured. It appears to me that vegetation must have suffered. I remember that, some years ago, after a frost somewhat similar, the farmers did not think frost had injured clover. Later it did not yield much honey, and when

the farmers came to cut the clover the weight secured from the fields was a great disappointment to them. Time will tell.

I have a letter from a beekeeper in the Maritime provinces telling me that their bees had not been able to fly more than ten days since they had been placed on their summer stands. We have found it an advantage to give a five-pound jar of syrup to each colony.

Brantford, Canada, May 27.

BEAR CREEK APIARY

BY E. R. ROOT

One afternoon when I was in attendance at the convention at Denver, Feb. 16 to 18, I took a drive out with Herman Rauchfuss, with several others, in his auto, out to the foot-hills of the Rockies, in the immediate vicinity of Denver. Not far from those foot-hills Mr. Rauchfuss has one of his out-yards called the Bear Creek apiary. This contains 228 colonies of bees, and is arranged in rows in the manner shown. It is a neat, well-kept yard. I stopped long enough to take a snapshot, and here it is. The bees have a range of alfalfa and other mountain plants in the vicinity. The territory around here is not overstocked, says Mr. Rauchfuss, and there are other good locations where there are practically no bees.

I would hardly dare to make this statement that there is room for more bees here, as most good localities are already overstocked; but Mr. Rauchfuss is acknowledged to be one of the best beekeepers in Colorado. It is evident he knows this particular locality, and whether it will support any more bees. His attitude toward possible competitors is as generous as it is liberal. He did say, however, that one beekeeper had been there and "had gone, thank fortune." If *that* man ever came back there again he

would—well—er, it wouldn't do to say what he said—not that it was not printable, for it was; but it is not wise to say everything you know.

The Bear Creek apiary at the time of our visit was wintering nicely as far as could be seen; but the thing that interested me particularly was the fact that there were a large number of Caucasians; Mr. Rauchfuss said, contrary to our experience here at Medina, that this strain had given him no more trouble in regard to swarming than Italians. They were earlier to breed up, and, in fact, for all-around bees he liked them.

The drive in and around Denver among the foot-hills is interesting. On the occasion mentioned we went clear up into the hill country; and when I say *hill* country they are some hills all right. The elevation of this yard must have been considerably over 5000 feet, as we were constantly going up, up, up, all the time after we left Denver; but the little machine was equal to the occasion, and for all-around beework there is hardly anything better than a light car. It costs less to operate it per mile than any heavy machine.

BITTERWEED FATAL FOR WINTER STORES

BY S. A. FULLER

I have lost more bees this season than ever before. My colonies were never so strong in bees and stores in the fall. We had an early cold spell. When it warmed up, dead bees were hauled out by the thousand, and it has continued until now. Some strong colonies died out entirely, leaving quite an amount of stores. In all, up to date, I have lost 14 colonies out of 175, and

many are now very weak. I have never had such an experience, and do not know what to make of it. Our fruit-trees (peaches and plums) are just now in bloom, a month late. We have had cold freezing weather with snow up to this date. To-day is the first real spring day.

Later.—I had no aster honey last fall, but did have 1000 lbs. of bitterweed (yellow

Bear Creek Apiary, owned by Rauchfuss Brothers, near Denver, Col. This apiary contains 238 colonies, and is situated near the foot-hills of the Rockies, on elevated ground where the bees can command a view of the range and of the entire country. It is in this yard that Herman Rauchfuss has their Caucasians which have given them such excellent satisfaction. We wrote him, saying that in our write-up of the yard we would be careful about getting beekeepers to overstock the territory. On date of April 5 he writes, "You need not say any thing about the locality being overcrowded, for there are lots of good locations where there are practically no bees."

dog-fennel). I used to feed those colonies which were light the latter part of August and the early part of September. I had some fifteen swarms in October. I gave them two, three, and four frames of this honey, and they were the first to go. Those that I did not feed came through all right. Right now in front of 100 hives are enough dead bees to make an ordinary swarm; but now they are building up fast. I find twelve queenless colonies. I am quite sure in my case it was bitterweed which caused my trouble.

It was the first time my bees ever stored any of it that I detected. I noticed, in opening the hives after the swarms had died, there was a very foul smell. There are no other large apiaries here, but many of two to ten colonies. Many have lost all or

a part of them. I hope we may locate the cause, and thereby find a remedy.

Helena, Ark., April 15.

7 TENNESSEE BEEKEEPERS TALK OVER PROBLEMS

BY J. M. BUCHANAN

A special meeting of the Tennessee Beekeepers' Association was held at Chattanooga, Tenn., April 28, 29, in connection with the Southern Conference for Educa-

tion and Industry. Dr. E. F. Phillips called the meeting to order, and gave a talk on the "Essentials of Beekeeping." "Sources of Tennessee Honey" was the subject of a paper read by J. M. Buchanan, of Franklin, Tenn., who also spoke on "Co-operation in Improving Beekeeping Conditions in the South." J. J. Wilder gave an interesting account of the honey-plants of Georgia and Florida.

On the second day the subject of "Disease Control" was taken up and ably presented by G. M. Bentley, State Entomologist, and Dr. J. S. Ward, State Apiary Inspector. Dr. E.

Franklin Triangle and court-house, where the conference meetings were held.

F. Phillips spoke on "The Need of Better Winter Protection." Dr. Ward and Mr. Wilder gave demonstrations on handling bees.

There was a good attendance at the meetings, and much interest was manifested. Franklin, Tenn.

THE TEN-HOUR DAY FOR BEES

BY C. E. FOWLER

How far do bees fly? how long are they gone? how many trips a day do they make? are very interesting topics, and I should like to give a little of my own experience.

Last August, when honey was very scarce, a neighbor asked me to remove a swarm of bees from his roof so the carpenters could shingle it. I spent one day trying to save the bees, using first two Porter escapes; but the bees went right through them the wrong way.

I do not condemn the bee-escapes, as the bees were, most of them, trying to get into their home. Perhaps the inside bees, in trying to get out, wedged it open. After I got the escapes in place I could not get them off to look at them, as they were fastened on the inside. Then I made one out of watch-springs; and by the time I got it working the bees were going through the roof like water through a sieve, so I decided to sulphur them.

I commenced the next morning about seven o'clock, after most of the field bees were gone. After killing the bees in the nest with sulphur I commenced to kill the returning bees, supposing, of course, that they would all be back in a couple of hours; but to my great surprise they kept coming back for ten hours, and were still coming back at 5 P. M. The next morning there was a gill of bees in a bunch hanging on the edge of the roof. Now, some of these bees made only one trip in ten hours. How far did they travel? If they spent a third of the time going, a third loading, and another third coming back, and traveled 30 miles an hour, they must have

gone 100 miles. Of course they did not go that distance; but how far did they go? They seemed to be coming back nearly as fast at noon as at 8 o'clock, and gradually dwindled until 5 o'clock.

I found that they had a great many holes in the roof stopped up which they opened when they could not get through the bee-escape.

Nectar and pollen from apple-blossoms. Note the mass of pollen on the leg of the bee and the manner in which the bee spreads the stamens to get at the nectary of the blossom.

The bees were in the gable end in the projecting cornice, occupying a space about 6 x 14 x 36 inches, and had stored about 50 pounds of honey.

As I was closing the hole I saw a lot of comb about two feet below, and thought I had discovered another swarm; but red squirrels had been robbing the bees, as the pieces of comb were mixed with nutshells.

Hammondton, N. J.

THE BEEKEEPER WHO IS NEVER STUNG

BY THE AMATEUR

He that keepeth bees among you, and saith he never gets stung, is a liar and the truth is in him not.

The beauty of using quotations from the Bible is that you can take anywhere from one word up and prove anything you wish to prove. The text here is partly from the Scriptures, especially the style, but mostly from somewhere else.

Being very susceptible for a time to all new ideas and innovations, I listened to the wise ones telling how they had handled bees for years and had never been stung. Of

One day I questioned a wise man.

course I tried to solve the mystery, and pursued it as far as I could without putting up any good money for the "secret." I now remember that none of those possessing the remarkable knowledge were among the successful beekeepers of the neighborhood. One day I questioned a wise man for two or three hours till he offered to sell me the secret for, I think, \$3.49. I concluded he was still about a dollar too high, and that I'd better go home and look it up in the A B C and X Y Z. The nearest it came to what I wanted was that I should procure a veil, smoker, gloves, etc. But the wise man didn't use "sich truck." It wasn't necessary. Well, I gave up ever becoming possessor of the secret of knowing how to handle bees at all times under all circumstances without getting stung. But Fortune had ordained otherwise; for when my despair was the deepest

the setting was being arranged for my entire enlightenment, and I didn't need to give up the \$3.49 either. It all happened this way:

One hot day in June when the honey-flow was going off I was

grafting some queen-cells. I was busy at my work, and didn't know any one was within half a mile of me, when I heard a greeting from some one close behind me.

"Howdy, kid? Be ye the Amateur beekeeper?"

I looked up and saw a stranger. A description may as well be given here as anywhere. But the reader must bear in mind it was my first meeting with the stranger, and up to this time my last. He was a man about 45 years old, 6 feet 2 inches tall; and if he had been a beef steer I'd have said he was rather raw-boned; but as he was a man I might say his contour was irregular, with prominent facial features. He was dressed in a black suit made for his youngest brother. The pants, I well remember, fitted him snugly, and failed to connect with his shoe tops by two inches. This description may be wrong in parts, but I'll swear to that part applying to the legs, for I saw more of them than any other part.

I said, "Glad to see you. Yes, that's my name; but let me get you a veil. The bees are rather cross to-day."

He looked at me severely. "Now, look-a-here. I never take stock in sich truck—wouldn't wear it. Bees never sting me!"

"But," I persisted, "I have a veil in the honey-house, and my bees are quite cross to-day."

"Now, son, I handled bees when you wuzn't knee-high to a grasshopper, and I never wuz stung but twice in my life—one'n when I set down on a bee."

I don't remember now when the other time was, but presume it was when a bee sat down on him.

It might be well to state right here that this was the first time in my life I had ever seen one of those immune fellows among the bees, and I thought I might get a pointer or two from him while he was undergoing the acid test.

"I came up to talk to you about taking an agency on a gum I invented back in Missouri, and if you are the feller I take ye to be I'll give ye the exclusive agency of

My visitor grew eloquent.

"Howdy, kid? Be ye the Amateur Beekeeper?"

this whole county; but ye're busy now; finish takin' them maggots out and puttin' 'em whar ye want 'em and I'll show ye the principles of a little model I have with me."

The grafting had been explained as I had read it in the A B C.

Every beekeeper is said to have in his apiary a colony or two that can be relied

He trotted, ran, and then galloped.

upon in an emergency, and I am no exception. Mine was next to my breeding queen; for though I requeneed this colony twice it still retained its proclivities to sting on the slightest provocation, and I gave up trying to breed out this propensity, attributing it to "locality."

My visitor, in explaining his patent "gum," grew eloquent, swinging his leg like the baton of the musical director in an old-fashioned camp-meeting, and inadvertently struck the colony just behind him with his heel. Instantly they were upon him—ankles, legs, and face; and, although he protested fiercely that they didn't sting him when I asked him, I know that if bees were to go through the same process on my face I'd consider I had been stung. That is not all. They kept coming.

"Shall I give them smoke? I fear they will sting you."

"They won't sting if ye don't strike at 'em," he said.

Now, I am a rather human sort of person; and to clear my conscience I will confess that I was interested in (I almost said enjoyed) the situation. You would have thought those bees suddenly discovered some rare honey-plant right at their door from the attention they gave him. However, as they crawled up those tight black pant-legs they more nearly resembled bees trying to gather pollen from the goldenrod.

I did most of the talking now, for I didn't want to lose an opportunity of finding out how to keep from getting stung when in a tight place, and this man was backing off. Just then one hit him on the "dollar" of his nose. He snorted like a scared colt. I could see by the pained expression on his face that the half-hundred bees working on his legs were also beginning to penetrate the epidermis. I could no longer interest him in conversation. He backed off, tried to walk out of the apiary with dignity, but he couldn't get away fast enough. He

trotted, ran, and then galloped. He bounded over the small brush like a tiger. Long after he was out of sight I could hear the smashing of limbs and the rolling of logs.

I had learned the secret of the fellow who never gets stung.

I don't know whether I was stung or not. I didn't feel it if I was. But I know I learned the secret of the fellow who never gets stung, and it didn't cost \$3.49.

Bees Rioting in Chili

In February, 1914, while walking along the banks of the Rio Grande about half a mile from my place, I came to an old log mill. Bees were so thick around it that it was almost impossible to see through them. Thinking they were after flour or meal I paid no more attention to them until three days later when I noticed them coming in loaded with something red. I again went to the mill and found a Mexican grinding chile. In spite of the fact that he had smudges to keep the bees out, they were actually fighting and rolling in the chile.

This year in March, I noticed the bees gathering sawdust or anything they could get for pollen. I put some graham flour out for them, and some chile also. In a short time the fun commenced. The bees could not have been more excited had I put out pure honey. They did not disturb the flour until they had used up the chile.

Velarde, N. M.

HENRY SEVERSON.

Loafing in June

BY GRACE ALLEN

Well, yes; I admit it is prosily true:

There are plenty and plenty of things to do
Besides loafing here. But the wonderful bees
Are humming so steadily under the trees!

Then, too, there are roses and hints of a breeze,
And a marvel of green and blue!

Oh! how can you think on a morning in June,
When grasses are swaying and bees are a-croon,
That hurry and effort are always best!

My soul is adrift on a quieter quest—
The calm and content of a soft-breathing rest
As I pause with the bees in June.

Heads of Grain from Different Fields

The Backlot Buzzer

Well, here we are. Got 'em all nailed together but the last frame, and two pieces missing.

White Clover, but No White-clover Honey

Bees in this vicinity wintered well. Of 43 colonies cellared the last week of November, 42 came forth alive, and all in good condition when taken from the cellar, one half March 15, and the rest the first week of April.

The dead colony had no less than 20 pounds of honey, and the cause of death was paralysis with which they were attacked before putting into the cellar.

That surely is a fine picture of clover in Wisconsin, p. 360, May 1; but it does not look like white clover; and even if it is, it would be no guarantee that we should get any honey from it. As a matter of fact, we have had oceans of white clover in this section for the last two years; but it had no more nectar than pansy bloom.

Basswood, too, was nearly devoid of nectar in these parts last season.

White clover has wintered well, and we shall still look for honey from this source, even after our former disappointments.

Fruit-bloom is on, and the bees are improving their time gathering from the heaviest fruit-bloom we have seen for years. We have had no frosts to date to damage fruit-bloom. Dandelion bloom, too, is on, and is attracting the bees.

CARRYING BEES IN AND OUT OF THE CELLAR.

I read what Elias Fox says, page 382, May 1, on carrying bees out of the cellar by night, and wish to support his statement as being the best plan. I have followed this way for several years to my entire satisfaction. But for putting them into the cellar I reverse the time of day. Instead of the

late evening hour I use the early morning hours, after a cool or cold night.

My working plan to put bees in or out of the cellar is this: I fill a large gunny sack with hay or straw, put it on my Daisy wheelbarrow, and very carefully put each hive on this cushion and wheel it to or from my beeyard over a carefully prepared way with so little disturbance of the bees that I hardly ever find it necessary to close the entrance.

Manawa, Wis., May 19.

E. E. COLIEN.

Avoid Too Thick a Fence Separator

In using fences for plain sections is there any advantage, aside from better-filled sections, in using a $\frac{3}{8}$ -inch-thick fence instead of the $\frac{1}{4}$ -inch-thick fence? In using beeway sections as you do, the bees, in my estimation, get a little better than a $\frac{1}{4}$ -inch entrance into the super, and I thought perhaps bees would more readily enter and work in the super with the $\frac{3}{8}$ -inch fence than when using the $\frac{1}{4}$ -inch. What's the truth and general experience in this particular?

[Dr. Miller replies:]

It is not entirely clear just what you mean as to thickness. The fences I have are about $\frac{3}{8}$ inch thick at the posts, with the rails of the fence, the separator part, about 1-16. Fences may be made of different thicknesses, and I don't know whether the $\frac{1}{4}$ you mention refers to the posts or the rails. However, the general principle is all the same, and the question is as to the effect of increasing the thickness.

In the first place, I don't believe you will find that enlarging the passageway will make any very great difference as to the bees passing through or working above. Anything more than a sixth of an inch (the slots in a queen-excluder are about 1-6) will give as free passage as an inch, and the bees will work just as well over it. If you increase the thickness of the posts without increasing the thickness of the rails, that will make the comb thicker, increasing the danger of marring it. If you increase alike the thickness of posts and rails, that will leave the comb the same thickness, but will increase the tendency to rigidity in the section.

On the whole, if you make any increase in thickness, better try it first on a small scale.

Marengo, Ill.

The Critical Period in Queen Incubation

You have doubtless had experience in rearing queens in incubators with artificial heat. Can you tell me why it is that queens so reared out of contact with bees are so prone to die at the age of from two to four days? I have had a great deal of difficulty in rearing virgins past the fourth day; whereas if I get them five or six days old they seem to be able to live on almost indefinitely, or at least for a week or so. I understand my experience is common. I am pretty sure it is a matter neither of confinement, temperature, nor moisture, and have about decided it is improper food, but have not gotten any that will supply the need.

Seattle, Wash.

GEO. H. BISHOP.

[Your trouble is doubtless due to having the temperature too high or too low. The internal temperature of a hive—that is, the proper one for raising cells—is a little lower than the temperature necessary for hatching eggs for chickens. We have referred this matter to our man who has charge of our queen-rearing, and he says that with plenty of ventilation, and temperature at about 97, he secures strong

bright virgins in an incubator; and that, moreover, he has no trouble in introducing them over four days old. Good extracted honey is the best feed for virgins. Get your temperature right and feed extracted honey, and you will probably have no trouble. —Eo.]

A New Arrangement of Windows and Doors

In reading an article by G. C. Greiner some time ago I conceived the idea of having two doors in my honey-house. This makes it possible to keep one door open all the time, screened, of course, while the honey can be carried in at the other door, where the bees do not bother when it is opened and shut.

Bees escape from the window to the south in the room with the two outside doors. This gives light also while the doors are closed. It is quite close to the door, but there appeared to be no other place for it. It was necessary to have one window in the first room on the sunny side, since bees escape more readily on the warm side of the building.

The building is located west of the apiary, where it is both convenient and pleasant. Dimensions are 16 x 12.

East Avon, N. Y.

A. C. GILBERT.

Major Shallard's Honey-room Burned Out

In April I had the misfortune to have my honey-room at the home farm, South Woodburn, completely destroyed by fire. The building was of iron, 16 x 13 x 14, and contained among other things 2000 pounds of wax, eight-frame power extractor, wax-press, foundation mill, a quantity of carpenter's tools, jig-saw, etc. I first heard the roar of the flames at 8 o'clock in the evening; and on running out I saw the flames shooting out of the window above the extractor-stand. Help arrived almost immediately, and we got the engine and saw-benches away, and a quantity of hive material in the flat. We could get nothing out of the building. The heat from the burning wax was so great that it melted the iron castings on the wax-press and also on the extractor. An hour after the fire started the whole building was red hot, and looked like a gigantic

glowing lantern. It was utterly impossible to get near it, and the water available had no effect. There was practically no insurance. I have the building up again all ready for extracting; but having to pay out £125 to replace the wax is not at all pleasant, especially as the season has been a very bad one. The loss is over £200.

S. Woodburn, March 25.

MAJOR SHALLARD.

A Beginner's First Winter

Having spent the best twenty-six years of my life as a traveling man over the entire United States, and now having retired, and being a lover of bees, I have taken up beekeeping for the pleasure there is in it. While traveling I tried to keep four or five colonies; but not being here to care for them they were a failure, as everything is without proper care.

I purchased six stands of a friend, and went to work. Although the business was practically a total failure in Minnesota last year, I found myself in the fall with 16 colonies and 15 lbs. of section honey, aside from winter stores. All were heavy but five. I feared these five would not winter; but I fed them for two weeks on sugar and water, placed them in the cellar with the rest Nov. 15, with about 10 lbs. of stores each. I have a root cellar separate from the furnace-room, in which I set the bees. Over the hives I placed a ventilator 2½ x 3 feet, with a 2½-inch pipe extending through the window.

To do this I took out one pane of glass and replaced it with galvanized iron, so I could cut the hole to fit my pipe. Twice a week when carrying out ashes from the furnace I would open all the doors to the outside, and let in the fresh air for ten minutes. In extremely cold weather I would open the door into the furnace-room every night, thus holding the average temperature close to 45 degrees all winter. I set them out April 4, and found them all in fine order, but thought best to feed the light stands for two weeks. All are doing finely. I think I have thoroughly demonstrated that cellar wintering is the most successful plan if thoroughly looked after.

This year looks now to be a much better season, two weeks earlier than last. In the place of natural swarming I will experiment with the Alexander plan of dividing.

Fairmont, Minn.

M. T. HAINES.

Comb Honey from Two-story Hive

G. H. R., in GLEANINGS for April 15, page 335, in answer to W. L. Sherman, who asks, "What shall I do with my two-story eight-frame hives of bees in the spring when running for comb honey?" is mistaken when he says, "It is practically impossible to produce comb honey on top of a two-story hive."

I do not know how it is in Wisconsin; but I do know it works all right in Southern Florida.

In March and April the orange-trees bloom here, and my brood-chambers were so full last January that I thought of extracting a part of it from the frames to give the queen more room for depositing eggs therein, and have a larger working force when the orange bloomed. I undertook but one hive; and as there was but little bloom at that time producing nectar, the bees flocked in great numbers to the open hive, robbing.

I abandoned it, and thought out another plan. On each hive I placed one super of twenty-four sections on top of my eight-frame hives. I then constructed some brood-chambers without bottom-boards and placed them in the beeyard for future use.

My first swarm issued on March 15, and after that it was a daily occurrence until all had swarmed.

The swarms were hived in the hiving-box. The hive from which they issued was opened and the

combs examined. All queen-cells were removed, and the frames, bees, and brood placed in the bottomless brood-chamber. The old hive was furnished with empty frames; and the bottomless chamber, containing the frames and bees, was placed on top of the old chamber. The colony was then returned to old quarters—the old stand.

An entrance had been previously cut in the new bottomless brood-chamber, giving two entrances. I have already taken two supers of twenty-four sections each from many hives, and from all appearances at present I shall be able to get one or two more in a short time, leaving plenty of honey in the brood-frames for the colony.

I don't expect to come anywhere near my old friend Dr. C. C. Miller in number of sections from one colony; but for appearance and quality I'd like to exhibit with him.

Tampa, Fla.

WILLIAM P. HENDERSON.

A Novel Hive-record

I find a record-sheet a great help in keeping track of the condition of my different colonies. The sheets may be filed away as a record, or copied in a record-book.

I find it much easier to scratch off this slip as the conditions are noted than to write each item down. It is much more accurate than to attempt to remember what one has seen after the work is done.

5-6-15

CLIPPED	
NOT-CL'PD	DRONE
GRUB <i>in g-cell</i>	1 2 3 4 5
EGG <i>in g-cell</i>	6 7 8 9 10
SEALED <i>g-cell</i>	
Introduced	Supers-Given
LAYING	SECTIONS <i>taken 8/6</i>
NO Q-C	SWARMED
CROSS	
GENTLE	STUNG

When the first frame is removed and found to be full of honey I draw a line through figure one, under "Honey." Frame two has some honey in, and a cross is put before figure two; frame three has some brood in; and figure three under "Brood" has a cross in front of it. Frame four is full of brood, and so figure four has a line drawn through. The queen is seen on frame four, and "Saw" is crossed off; and as there are eggs in the cells, "laying" is crossed off. If this colony is cross, "Cross" is marked off; and if I get a sting or two while working this colony, "stung" is marked; and if she has many records so marked when the time of year comes for superseding, her head is pinched.

The slips cost me about a dollar a thousand, and are put up in pads of a hundred each for convenience, and may be torn off as used.

Princeton, Ill., Feb. 6.

G. R. RICHARDSON.

Bee Gums in the Mountains

Bees wintered exceedingly well in this section of West Virginia—scarcely any loss at all. There has been a good early bloom, and bees have stored a little honey. Prospects are fine for a good honey year. How would some of you bee experts like to tackle a job of 150 colonies of bees in the old-fashioned round gum?

I just returned from a trip up the Williams River, trout-fishing. We stayed with a man who had about 150 stands, and every one was the round hive. I asked if they would not be better to handle in the modern hive. He said he didn't think they would, as he had never seen a patent hive. I explained the use of the modern hive to him, and he has a notion to try two or three when he gets time. On making inquiries about how they wintered he said he had lost only ten or fifteen this season, but last year he lost fifty colonies. He is situated among the mountains where the poplar and basswood are untouched. What could an experienced beeman do if he had his bees located where this man is? Don't you envy him?

Bolair, W. Va., May 17. L. W. STARCHER.

Heavy Minnesota Loss

Bees in this vicinity are almost a total loss. I have saved perhaps more than any one else, but have only 50 colonies left out of 130 placed in the cellar. Many of those are very weak. Our largest beekeepers who had from 100 to 125 colonies each last fall have lost all or nearly all, while most of the small owners are cleaned out completely. Numbers of colonies died with honey in combs.

April was warm; but it turned cold and rainy as soon as fruit-bloom came on, and the same condition still continues.

On May 18 everything was buried in snow, and a hard freeze was on.

Excelsior, Minn.

MRS. W. S. WINGATE.

Calk Feeder with Paraffine

Mr. W. A. Sillifant writes on page 338, April 15, describing a method of making metal division-board feeders. If he will pour melted paraffine wax in the wood feeders, and, while hot, tilt the feeders so that it will run or flow into each joint of the feeder, he will have no trouble. What does not stick in the joints of the feeder should be turned back into the melting-pot. The wood can be made or bought cheaper than metal, and is not as cold as metal, even when coated with cork or sawdust both inside and outside.

Wabash, Ind.

F. J. REDDIG.

Low Prices in Fresno, Cal.

The honey crop of the mountain districts along the Coast Range will not be large this year on account of very little rain. We will hope for better prices than 3½ cts., which is being offered at this time. We have a fine quality of honey—always light amber—and it never granulates. It seems a shame that more of it is not used in the United States, and that we have to depend on Germany for our output.

Coalinga, Cal.

MRS. H. T. CHRISMAN.

Bees in Orchards

There is a kind of bee craze here now. All the orchard men are inviting the beemen to come on, and are buying hives to put in their orchards. Some time ago they wanted to declare bees a nuisance. "Every dog has his day."

New Almadin, Cal.

PAT KEATING.

A. I. Root

OUR HOMES

Editor

Unto him that smiteth thee on the one cheek offer also the other.—LUKE 6:29.

Why lodge ye about the wall? If ye do so again, I will lay hands on you.—NEHEMIAH 13:21.

Behold, I create new heavens and a new earth; and the former shall not be remembered, nor come into mind.—ISAIAH 65:17.

Mr. A. I. Root:—I have often thought of telling you how I have enjoyed your Home department in GLEANINGS; but I notice a change in sentiment in the issue for May 15. It doesn't sound like A. I. Root—seems as if he were gone and somebody else had taken his place. I certainly feel that there were a lot of astonished readers when they read your answers to those two letters and noted your attitude in regard to the taking of human life. Right now the major portion of the world is in a great conflict—all struggling for the mastery. Right now when the subject is before the people, and the awfulness of war is in evidence on every hand, is our opportune time as never before to teach against it. That old theory of preserving peace by preparing for war has been proven defective, as the experience of the nations will testify. In your article you mention a few instances where a quick shot was effective in saving human life; but how would you like to be the one who fired the shot? Should we provide a six-shooter for our ministers, so they may have them in easy reach to use on some dear brother or sister in case of sudden violent insanity in the congregation? Are we not told to be wise as serpents and harmless as doves? Please don't hide behind George Washington. I do not think we should use him for an argument in favor of war. We have the Bible for our guide, and no one can read the teachings of Jesus Christ and believe them, and at the same time believe in war.

The chances are that there will always be war as long as this present dispensation lasts; but should the Christian people sit idly by and say nothing? or, worse, should they even say a few words in its favor?

You mention the man with "foolish religious principles." His principles are outlined in Matt. 5:38-45; also Luke 6:28, 29.

All the above is said with the utmost respect, and in a spirit of love. It seems to me we cannot be too careful about our influence. You are a man who has a lot of influence; and you are preaching to a large audience, and you will no doubt be held responsible for the position you take on this question. Let us not be wishy-washy. Let us take a stand on the side with the Master, for that is sure ground. I wish you would pray over this again; and, if the Spirit directs you, tell your readers about it.

John says we are to try the spirits to see if they are of God. See if they line up with the teachings of the word. I for one am not satisfied with your position, and I don't think the Master is either.

Morrill, Kan., May 27.

F. E. POISTER.

Please accept my thanks, my good friend, for your kind letter above, although it is very plain and square-footed. Yes, you are right—my conscience did trouble me somewhat in regard to that Home paper, for it was, as you state it, a new departure; and yet God knows we need laws and law enforcement—yes, better law enforcement than we have had in times past. Permit me, dear brother, once more, to picture the circumstances under which I would use a revolver,

if I had one, or anything else I could get hold of. Suppose a fiend in human form was trying to kidnap a young girl—say your daughter or mine, or it ought not to make any difference whose daughter she was. Suppose this fiend in human shape, as I have said, was carrying this girl away by force to bring her up to a life of shame. This has been done, and is being done just now, as our daily papers bear record. Now, if this imp of Satan could not be stopped in any other way, I would take a revolver or anything else I could get hold of, and fight; and if I succeeded in killing him I do not think my conscience would trouble me. The laws of our land, and the people, and the law of God would hold me guiltless.

There are other places where all or at least most of us are liable to be where, in order to save innocent, unoffending life, we must sacrifice a bad life. A clipping from the *Sunday School Times*, telling of how a missionary fought to save his life, brings out many important points.

Going to all sorts of places day and night as I did, in no case was I harmed.

Perhaps only once was I in personal danger; but the occasion was so interesting that there was no time to think of the danger.

I had arrived late at night at the home of a Christian. The country thereabout was infested with robbers, smugglers, thieves, disbanded soldiers, and destitutes and thugs—all tough to the *nth* degree. The people spoke bitterly of the inability and unwillingness of the magistrates to restrain them.

It was cold winter weather. The prophet's chamber I occupied had once been a stable, and, as a granary and general catch-all, had not yet lost its pristine flavor. So, as was my custom when not necessary to share quarters with my barrow man and others, I had stripped from the small window all the ragged paper that was pasted on the slats serving for a window frame, and had fastened the door wide open, and placed my folding-cot near it. Cold night air, deliciously fresh, filled the room. My room abutted on the narrow alley. In front of its door was a small yard whose streetward wall was about seven feet high.

During the night a slight noise in my room awakened me. By the light of a full moon, pouring through open door and window, I saw two men standing before one of my boxes, the one I had purposely placed in the corner of the room furthest from the door. It contained my personal effects, also payments for evangelists and schoolteachers—men who, for their part in the re-making of New China, receive the munificent salaries of twenty dollars a year.

The cover was up, leaning against the wall, and they were taking out the contents. To get out of the room they had to pass my bed—for which I was thankful. As a member of the University of Pennsylvania athletic squad I had been lucky enough to get on the police force of Philadelphia "for some inside experiences." In that work we had learned a few things that admirably supplemented some football tricks. I remember hurriedly thanking the Lord for it all. I got from the bed as cautiously and

quickly as possible, but not so quickly as to save a rush at me.

Chinese thieves expect no quarter, and usually give none. When I retired I had mechanically laid a knife—big, sharp, and heavy—under my cot, within reach of my hand. It flashed over me: "Better not use that knife." And instantly I made a flying football dive for the foremost man, who was coming straight at me. I caught him in what is technically called "sure," just above the knees. The momentum of my weight toppled him backward like a log. He struck his head violently on the hard earthen floor, and one thief was temporarily out of business. I, of course, went down with him, and the other fellow was immediately on my back and brandishing a wicked corn-cutter. He lost it in the scuffle, and I was able to rise up with him clinging and shake his grip down to my waist. That was a poor hold to impede an opponent, as any football player knows.

Whirling hard, I broke his grip, faced him, and with a swift twist of his neck, tripped and jammed him down to the ground, knee on his chest, and fingers digging into his throat. The family heard the fracas and were soon on the scene, and in short order the rascals were bound hand and foot.

I had not time nor inclination to make a long journey to the county-seat and accuse the robbers before the magistrate. So I turned them over to the indignant villagers, who, under the village elders, gave them such a paddling as rascals rarely get outside the *yamens*. After some rough handling they were loosed, with the admonition that in the future, when out on their forays, they steer clear of that village.

Please note that this good missionary would probably have lost his life had he not in former years been a member of an athletic club. He was also an expert, as we take it, in football, and he says he remembered hurriedly to *thank God* for it all—that is, his first prayer was to thank the Lord for the *skill* he had acquired in athletics and football games. Now, here is one thing I admire him for. In contemplation of sudden attack he had placed a "big sharp heavy knife" within reach. He says it flashed through his mind, "Better not use the knife." I think it was the Holy Spirit that prompted this decision. He not only saved his own life, but he avoided taking life. In every emergency like this our constant prayer should be that we might avoid the *necessity* of taking life. In fact, I am not sure that we are ever excusable in taking life merely to save property. Just at this crisis in human history, it is right and proper that every follower of the Lord Jesus Christ should be considering and praying over this matter of war. My good friend W. A. Selser, of Philadelphia, who has no doubt been impressed with the Billy Sunday sermons, has just paid us a visit. He takes the ground, as I understand it, with the writer at the head of this article, that if Belgium had permitted the German troops to pass through their territory unhindered, and had turned "the other cheek also," as we have it in our text, this whole great war might have been averted.

Permit me, in closing, to give an extract from a sermon by our pastor, Rev. H. Samuel Fritsch, given to the remaining G. A. R. veterans on the second Sunday preceding Memorial day, May 23:

We need to remind ourselves that, just as God gives to different individuals different tasks, some one thing and some another, so also God gives to different generations different duties.

We need to remind ourselves of this truth, especially and particularly and emphatically in these days when half the world is war-crazy, and there is immediate danger of the other half of the world catching the disease!

There is a real and immediate danger that America, in the exciting and irritating atmosphere of the European war, lose her head. There are some people who feel that the only real patriotism is the patriotism that fights and kills. We need to remind ourselves to-day in unambiguous and unequivocal language that there are two kinds of war—necessary war which is patriotic and divine; unnecessary war which is treason and devilish.

You and your sleeping comrades served your country by the war method. You fought for a principle, for the perpetuation of the government, for the freedom of humanity. War was the task that your generation laid upon you, and we honor and commend you because you served your own generation in that generation's own and only way.

But it does not follow that therefore the task of this generation must also be war. I believe that, in spite of the irritating and iniquitous situation arising out of the European war, our President is right in his attitude of watchful waiting; and that to-day, from a mistaken motive of defending the national honor, to start a war and sacrifice the flower of America's young manhood upon the altar of jingoistic pride would be nothing short of damnable treason!

I believe that such men as Woodrow Wilson, William Howard Taft, and William Jennings Bryan are absolutely right when they assure us that America's task in this world-wide and world-wild holocaust and cataclysm is something other than war. And if the present generation in America is opposed to war and preaches against war, it is not that we denounce or discount the method and the task of the past generation; it is simply that we recognize the fact that the method and the task of the present generation is different from that of the past. And the only way in which we can serve our generation is to serve it according to the method and needs of our generation.

In regard to the scripture quotation from the good brother whose letter heads this Home paper, my understanding is that these passages in our texts refer mainly to neighborhood differences. It is a strong injunction to put up with injustice and abuse rather than to fight and go to law; but I do not think it applies to the midnight assassin. Under the influence of drink, or perhaps the modern dope, cases come up every few days where some wretch murders a whole family. Now, are we to understand that the father and protector of this family should do nothing at all to protect himself or the loved ones? Shall he not fight, and be ready to *take* life in order to *save* life, when no other course is left open to him? Will our good friend Porter answer this?

In regard to having a revolver right handy on a shelf under the pulpit, no, my good brother, I would not keep a revolver there, and I would not have it anywhere unless in the hands of a duly appointed policeman. Years ago I did have a revolver which I kept under my pillow; but after my conversion I put it away, and have never handled one since, and, in fact, have scarcely seen one; and since you call attention to it, I think now I would rather take the small chance of being killed myself rather than to keep a revolver, thinking the time might come when I could save my life by the use of it. My long-time friend who is taking down these notes suggests right here that the Pilgrim fathers always went to church with guns to protect themselves from the Indians; and a similar condition may even now exist in some parts of the world. In the book of Nehemiah we read that in building the walls of Jerusalem the men wrought with one hand and in the other they held a weapon. Shall we not face conditions as they are *now*, and work and *pray* for the time coming when such things will be *needed no more*?

The midnight assassin and the highway robber are, I am convinced, largely the product of our saloons; and when they are banished from the face of the earth the need of taking life to save life will have largely passed away, as in the language of our second text. Let me repeat what I have said about Manatee Co., Florida. There has never been a saloon in that county, and, God helping us, there never will be one. As a result, my good neighbor Mr. Rood had a poultry-house undisturbed for years right up against the fence along the highway. A passerby could, in fact, reach through and get a chicken if he wanted to, and yet our population is largely *colored people* whose loose habits and fondness for "chicken" have been proverbial. So long as we have the rum traffic we must fight. May God be with us, and help us in this fight until the partnership now existing between our nation and the liquor-traffic shall be ended.

SOCIALISM, CHRISTIANITY, ETC.

Mr. A. I. Root:—In my copy of GLEANINGS for Dec. 1, under the heading of Our Homes, I noticed your views of socialism expressed, as likewise our brother Boone's. You stated that you were liable to put your foot in a hornet's nest if you discussed this subject. GLEANINGS has always seemed to be an impartial magazine based upon truth and not fiction.

Mr. Root, I admire your religious views, and am a lover of the Bible; and it was the Bible, and particularly the teachings of Christ, that first opened my eyes to the glaring injustice of the present capitalist system. This system uses the dollar as its god, and will end when one man owns the world and all in

it. It has held up profits as its Christ. For profit the liquor traffic exists, the tobacco traffic also, and the present social evil.

May I not say you were mistaken or misinformed when you stated the Socialist party was in favor of the liquor-traffic? We are for the prohibition of the manufacture and sale of liquor, or at least the majority are, throughout the world, and, likewise, the upbuilding of the laboring class. All men are or should be laboring men by the Bible's teaching.

Now, Mr. Root, is it the laboring man or capitalist that finance the old parties? As it is the capitalist, how can the laboring man expect laws made in his interest?

As God has put enough food, shelter, and clothing into this world for all, why do not all enjoy it? Is it right for one man to corner or own nearly all the necessities of life and withhold it from the producers? Why are not the things used publicly owned publicly? or the means of transportation, production, and distribution? This would be like a swarm of bees all working and producing for the common good. What would you do with a colony of bees that would allow the first workers of spring that collect pollen to hold up the colony for ten cells of bee-bread apiece for it?

While I do not like the manner of the attack of comrade Boone, I still maintain that all laboring men should support the socialist movement; also all professors of Christianity.

Newaygo, Mich., Dec. 24. A. A. WOODRUFF.

My good friend, if I understand you correctly, as you state it I am a Socialist. I do most vehemently object to one man or a gang of men cornering the necessities of life; and I am strongly in favor of government ownership, so we can all share alike, as fast as it can be brought about. I am greatly pleased to hear you say, indirectly if not directly, that socialism indorses the gospel of Christ Jesus. If this is true, then I gather from reading a great mass of periodicals that a large part of the Socialist party are "away off" in their ideas and methods. As socialism is pretty well up before the world, I leave our readers to judge. I agree with you that our old political parties have been dominated largely by capitalists. But this is fast passing away. The laboring people, and especially the farmers, are making themselves heard. The downfall of the liquor-traffic is a striking evidence of it.

Later.—Since the above was written I have seen somewhere a statement in regard to the number of people employed in the liquor business who belong to the union. I think it was a good many thousand; and inasmuch as these would lose their occupation by prohibition, it was stated the union could not indorse nor recommend prohibition.

A LETTER FROM TROUBLED MEXICO.

Mr. Root:—The reason that I delayed sending my subscription was that it seemed that foreigners would have to leave Mexico. I have asked a friend of mine who lives in California to renew my subscription. It is a great pity that your articles on gardening are not more widely known. From what I read in GLEAN-

INGS I should judge land in Florida to be more productive than in this much-praised portion of Mexico. Take, for instance, cassava. It appears that 25 lbs. per hill is not uncommon. Down here three or four pounds is a big yield, and it sells for 5 cts. per lb. Thirty-five bushels of corn per acre is also a big yield here. Under these conditions, Americans, in order to exploit tropical agriculture, have no necessity for desiring the protection that the stars and stripes afford them. F. H. BREAKELL.

Perez, V. C., Mexico, April 29.

My good friend, I am sure that our Florida soil is, as a rule, no better than yours. Where we got great yields, say $\frac{1}{2}$ bushel of dasheens from a hill, we turned under a great quantity of vegetation—grass,

leaves, palmetto, weeds, etc. It was considerable labor in the first place; and since then we have been using poultry manure and stable manure and chemical fertilizers to some extent, keeping down all weeds until the cassava gets a start. There is also a vast difference in Florida soils. In fact, we often have good and bad spots on a single acre. But intelligent management will as a rule make the bad spots good unless they are exceedingly bad. May God grant that poor Mexico may have good protection, and that right speedily, such as we now enjoy here under the stars and stripes.

HIGH-PRESSURE GARDENING

SPINELESS CACTUS FROM TWO POINTS OF VIEW.

It is of great importance that the real truth about this plant be made known. On page 429, May 15, I told you of an advertiser who has ten different varieties, from 60 cents up to \$5 a leaf. I am now going to give him some free advertising.

I have told you before that I have one leaf of the fruit-bearing cactus that cost me \$1.75; and on page 473, June 1, we are informed there are buds on the leaf already, and we propose to keep our readers posted.

Now, here is a clipping from the circular that induced me to invest; and I must confess that the prospect of "fifty tons of beautiful and delicious fruit" is what got hold of me largely.

On good soil, some varieties of spineless cactus will produce fifty tons per acre the first year, one hundred tons the second year, two hundred tons the third year, and four hundred tons the fourth year, and fifty to two hundred tons per acre on poor sandy land, without irrigation or fertilizer, some varieties producing fifteen slabs the first year, forty-five the second, ninety the third, and one hundred and eighty the fourth. Some varieties will produce fifty tons of beautiful and delicious fruit per acre which can be kept like apples and shipped without ice, and which contains over 30 per cent more sugar than sugar cane does.

It has produced nearly fifty times its volume in one season, and over two hundred slabs from one slab within two years in north Florida, thereby exceeding the world's record elsewhere. It is growing successfully in several places in Florida now.

Monticello, Fla. SAMUEL KIDDER, Nurseryman.

It is true I have had in mind writing my good friend Prof. Rolfs, of the Florida Experiment Station, but for some reason I have neglected to do so; therefore you can imagine with what interest I read over and over the following, clipped from the Jacksonville *Times-Union* of May 20:

FROM DIRECTOR ROLFS.

Farm and Home, of Springfield, Mass., had the following recently:

"In *Farm and Home*, November 1, E. P. Powell states that the Florida Experiment Station reports favorably upon the results obtained by growing spineless cactus without irrigation. This is quite contrary to the facts. The results of the Florida Experiment Station with the growing of spineless cactus have been about as unfavorable as could well occur.

"Further down in the same article Mr. Powell states that fat cattle can be seen at the station that have never seen water otherwise than that which is produced by the cactus leaves. This is also contrary to the facts in the case.

"All of our attempts to grow spineless cactus, which include thirty varieties, as well as the attempts of the Department of Agriculture, have given negative results."

This is signed by P. H. Rolfs, Director Florida Experiment Station.

This is not all the information of the same nature we have in our possession, but the above will serve to show what is the attitude of agricultural scientists regarding spineless cactus. These men have experimented without any prejudice or personal interest against spineless cactus, and their conclusions all agree as to its lack of real merit. We special agents of the United States Department of Agriculture are under instructions to conserve the welfare of our demonstrators and co-operators, and have no personal ends to gain in warning the farmer against engaging in undertakings that threaten to take his money without giving him any return for the expenditure of his money and labor.

The Department of Agriculture, as I understand it, has been for some years making tests of Burbank's spineless cactus in California. The bulletin concerning it can be had on application. I have already made mention of it. Now, it is exceedingly important, especially to the good people of Florida, that they should have the *real truth* in regard to the spineless cactus. It was Burbank who gave it the boom, or at least the Burbank Company. We have been repeatedly told that Burbank himself is not responsible for what the *Burbank Company*

claims and advertises. This being true, he certainly has the power to forbid the use of his name did he choose to do so. Our California friends—at least a great part of them—indorse Burbank, and they feel hurt whenever I presume to criticise him or the Burbank Company. Very likely new facts are being daily brought out in regard to the cactus as well as everything else. I regret that Professor Rolfs did not put a date to what he says above. I am especially interested because there are people in the neighborhood of our Florida home who have invested as high as 1000 "slabs" for one planting. I hope to give our Florida readers photos of these plants occasionally, so they can see for themselves what growth these wonderful "creations" (and I hope they honestly deserve to be called such) are making.

Later.—Our good friend Borchers, of Laredo, Texas, has sent us something like half a dozen bulletins from the Department of Agriculture in regard to spineless cacti. From a "summary" from one of these bulletins I clip the following:

THE PRICKLY PEAR AS A FARM CROP.

The experimental plantation cost nearly \$9 an acre, including all expenses, beginning with the breaking of the raw prairie and ending with the cuttings properly placed. With good labor and proper management this expense, it is believed, could be reduced to \$6 or \$7 an acre. Even \$9 per acre is low for a plantation that does not require renewing for fifteen or twenty years.

A conservative estimate of the annual production of prickly pear under cultivation is 22 4-5 tons, or enough roughage for one bovine animal for a year from each acre of ground. This is to be harvested biennially.

Cattle, sheep, goats, swine, and even chickens will eat the crop readily at any time of the year.

Eight times as much growth of prickly pear has been secured under cultivation as was obtained without cultivation in ungrazed pastures.

More than six times as much roughage (actual feeding value) has been secured during the past two years from prickly pear as from sorghum.

From another one I quote as follows:

Our experiments seem to show that when prickly pear is fed with cured fodders or grains the digestibility of both is increased. For this reason prickly pear has a greater food value than is shown by its analysis and digestion coefficients.

The steers seldom drank water when fed prickly pear alone. In fact, in feeding a ration of 100 pounds of this feed per day the animals obtained from the feed over 8 gallons of water, which is more than was usually drunk by them when fed cured fodders alone.

Animals scour quite badly when fed prickly pear alone; besides, other feeds are needed to supply the proper amount of proteids; and for these reasons it is better not to feed it alone.

A ration for a 1000-pound milch cow of 50 pounds of prickly pear, 10 pounds of wheat bran, and 10 pounds of alfalfa would furnish about the correct theoretical amount of nutrients, in which the ratio of proteids to carbohydrates would be 1 to 5.46.

As both the above were from bulletins

published in 1908 (seven years ago), very likely considerable progress has been made; but as the above facts seem to be pretty well established, it gives me considerable enthusiasm. I am especially interested in growing spineless cacti for poultry.

KAOLIANG, A POSSIBLE RIVAL OF FETERITA.

We clip the following from the *Country-side Magazine*:

A NEW FOOD STUFF.

From South Dakota comes the news that kaoliang is being eaten with relish by man and beast. The School-of-Agriculture girls have made it into grid-dle-cakes, waffles, bread, doughnuts, muffins, and numbers of other goodies. Livestock eat the forage and seed-heads. The home economics department of the School of Agriculture is preparing a list of kaoliang recipes for distribution among the farm women of the state.

Kaoliang is a non-saccharine sorghum, introduced several years ago by the United States Department of Agriculture, to fill the demand for an early-ripening grain sorghum on the great plains of the North. It has been found to be a satisfactory yielder in the driest years. In a two-year test, it yielded better than corn. It matures about September 15.

Kaoliang is one of the forward steps in making the most of the earth. It is by such steps as this that men go forward toward the time when there will be plenty for each member of a world population inconceivably greater than ours. Kaoliang is a lesson in making the most of things as they are.

I have searched our catalogs, but can find no mention of kaoliang; neither have I heard of any such plant. We learn from the above that it was introduced by the Department of Agriculture several years ago. If so, some of our readers in South Dakota may be able to tell us something more about it.

While I am on this subject, our recent experiments in cooking feterita did not turn out to be as successful as when we tried it in Florida. The whole grain was boiled one whole forenoon, but it did not get soft as with our first experiment. The only reason I can offer for it just now is that the sample sent us by mail had been freshly harvested, and was easy to cook on that account. We shall soon be able to settle the matter, as you will see by the letter below, from our Florida garden:

I planted the cassavas about the 10th of May, and also the sweet potatoes. The jacobita is growing nicely, and is pretty. The feterita all headed out, and is beautiful. I am planning to send you a head of it when it gets ripe. The hens are not laying much. They all want to sit; but I shut them up to break them.

The wheat is higher than I am, and is still growing. Mr. Harrison had me get out three baskets of dasheens to send by mail. I am with Mr. Keller picking tomatoes.

Manatee, Fla., May 26.

WESLEY WELCH.

The grain mentioned above is the Egyptian wheat. When I left Florida the last of April it was not a foot high; and if it has grown higher than Wesley's head in just

thirty days it certainly seems to be a success in Florida.

DASHEENS TO DATE.

There were so many calls for the tubers in pound packages that we have just used up our stock brought from Florida some time ago. Since then we have been filling orders direct; and when Wesley wrote his letter they had three half-bushel baskets ready to mail. If any of our readers still want them, they can get them by sending postage to C. L. Harrison, Bradentown, Florida.

In regard to shipping tubers to foreign countries, we have just received a report from A. R. Stachling, of Berri, South Australia, which reads as follows:

We have a package of forty tubers that came to hand sound, with sprouts started on all except three.

RAINBOW CORN, ETC.

Mr. Root:—When I read the last GLEANINGS I learned why my Rainbow corn didn't have any rainbows. I planted the grain you sent me, and they all came up and are growing finely; but with the exception of a few leaves that have some little stripes of white on one edge it is as green as any corn. They have a joke on me now, as I gave it a conspicuous place in the front yard.

Dade City, Fla., May 21.

C. H. TIDD.

My good friend, do not be discouraged. I think when your corn gets a little taller you can see the rainbow colors all right. I remember when I first planted the rainbow corn I was a good deal discouraged, as it showed little or none of the colors until it

was toward a foot high; but a little later it went away ahead of my expectations.

"CORN-SCRATCHERS" FOR MAKING GREEN CORN MORE DIGESTIBLE.

Mr. Root:—I notice in GLEANINGS that you are interested in corn-scratchers. I enclose a sample of a home-made corn-cutter that I have made for friends. To remove corn from the cob for cooking, hold the ear of corn with one end resting in a dish. Slide the cutter over the rows of corn till all is cut, then reverse the cutter and scrape the pulp from the cob. It can be used for preparing the corn for eating from the cob. Score a section; prepare, and eat and repeat. The corn will almost fall in one's mouth.

WANTON D. SLOCUM.

North Dartmouth, Mass., April 1.

Since our remarks in regard to the above, several communications have been sent in. One of them describes a corn-scraper made of a piece of tin. The tin is first cut out something like the shape of a spoon flattened out; but the spoon part would, perhaps, be a little larger. Now, with a punch, V-shaped points are cut in the tin, the points being bent outward, something like a horseradish-grater. After these points are punched out, the spoon part is bent in a curve so as to fit the ear of corn. As you take it by the handle and draw it lengthwise over the corn, the sharp points will rasp or tear open the hulls. Our good friend, whose letter appears above, sent us a couple of very neat scratchers made of aluminum. I do not know whether he is prepared to furnish them for sale or not. You can find out by writing him.

POULTRY DEPARTMENT

STARTING EGGS UNDER HENS BEFORE PLACING THEM IN THE INCUBATOR.

I believe every one who has tried it is satisfied that better hatches are secured by giving eggs to sitting hens for the first three or four days. To go still further, a sitting hen will produce more fertile eggs than any incubator. We have abundant evidence of this. Our good friend Keyser, who is one of the best authorities on poultry in the world, said that he, some time ago, gave a sitting hen some eggs that had been thrown out of the incubator as being infertile; that is, the incubator had not succeeded in starting any germs. He afterward forgot all about it, and the hen succeeded in hatching chickens from the biggest part of those eggs that the incubator had declared to be non-fertile. The manufacturers of incubators are a little slow about acknowledging this—at least most of them are. If you doubt it you can test it yourself. I have

made several experiments along that line. I do not mean to say a hen will produce more good strong chickens from a given number of eggs than any incubator. Below is a letter along the same line:

Mr. Root:—We have been told that when eggs are placed a few days under a hen, and then transferred to the incubator the hatches will average better than if placed in the incubator in the beginning. It seems to me if this is true the hen must wear the bloom or mucilaginous substance off the egg so the embryo can breathe better. If this theory is correct, why not wash off this substance in water, then place them in the machine with the assurance that we shall get a better hatch! Please test this matter, and report in GLEANINGS if there is anything to it. If this idea has ever been presented in print I have never seen it.

Ozark, Mo., Jan. 30.

S. S. LAWING.

My good friend, I at one time had the same thing in mind which you mention; but I believe most people who have used incubators largely say they would rather not have the eggs washed at all. I have ob-

served as you have, that the hen, by rolling the eggs about, very soon rubs off the outside bloom of a newly laid egg. In order to get some idea of just how *much* a hen tumbles her eggs around I once slept with my head close to a box containing a sitting hen. For perhaps an hour or more after placing her in her new surroundings she did not make a move; but about midnight she commenced kicking those eggs around in such a way that it seemed she would certainly smash them against the sides of the box; and she kept it up so frequently for the rest of the night that I scarcely

got any sleep at all. No wonder the glutinous covering was scoured off.

Another thing that seems to run rather against your theory: about the best hatch I ever had, and some of the strongest chickens I ever had, were from a sitting hen that got out in some black sticky mud, and then got back on her nest. Her eggs were so daubed over with the dried-on mud that I did not expect to get a chicken; but I did not get time to wash them off, and the result was as I have told you. I do not think I have ever seen the matter touched on in any of the poultry journals.

TEMPERANCE

"GOD'S KINGDOM COMING" ONCE MORE.

When I found the following in the *Cleveland Plain Dealer* of May 25 I said, "May the Lord be praised for this unanimous decision of the engineers of America." Read it, and see if you cannot say the same.

ENGINEERS FAVOR DRINKLESS NATION; AMERICAN AND CANADIAN DELEGATES VOTE UNANIMOUSLY FOR PROHIBITION; DECLARE LIQUOR AND EFFICIENCY DO NOT GO HAND IN HAND.

The Brotherhood of Locomotive Engineers at the session at its convention yesterday afternoon indorsed state and national prohibition. This action was taken by unanimous vote of the 819 delegates, representing 74,000 locomotive engineers in all parts of the United States and Canada.

Immediately after the convention had voted on the prohibition question the Canadian delegation, composed of eighty-five delegates, asked for the privilege of taking a vote. This contingent then cast a unanimous vote indorsing prohibition in Canada.

The resolution was introduced unexpectedly. Several members took the floor in its support.

The action of the engineers was purely non-political. It indorsed no party, but simply went on record against the traffic in liquor.

SHOWS TREND OF TIMES.

"This is simply an indication of the trend of the times," said one of the officers of the organization after the meeting. "Engineers of North America have been trained for years that drink and efficiency do not run hand in hand.

"If any one needs a clear head it is the man in the cab. The fellow back in the sleeper may drink a cocktail if he wants to; but we who have to keep watching signals every minute know that if we are not at our best the man in the sleeper and we ourselves will pay with our lives for carelessness."

It was stated at yesterday's meeting that the report of the Interstate Commerce Commission for 1914 showed that of all the engineers in service in the United States last year only two ran past a signal, and one of these is believed to have been dead when he passed the signal.

Copies of the convention's action will be sent to the official organization headquarters of the political parties, and to others who may be interested in the movement to make the country dry.

I clip again from the *Plain Dealer* as follows:

The Ohio Women's Christian Temperance Union yesterday expressed its appreciation of the brother-

hood's action in indorsing state and national prohibition. The following telegram was received yesterday from Florence D. Richards, of Columbus, state president:

"The Brotherhood of Locomotive Engineers, Cleveland, O.: The Ohio Women's Christian Temperance Union sends greetings and grateful appreciation of your splendid resolution for prohibition. May the words of Moses, 'Blessed shalt thou be when thou comest in and blessed shalt thou be when thou goest out,' be verified to each member of your brotherhood.

FLORENCE D. RICHARDS,
President Ohio W. C. T. U."

KANSAS, THE "DIED-IN-THE-WOOL" PROHIBITION STATE.

Perhaps some of you will say that the story below has been told in *GLEANINGS* already—may be twice; but the following, which we clip from *Better Farming*, tells it in a little different manner; and, besides, it is something like the "old, old story"—it ought to be told again and again, until every other state in the Union, and especially the wet states, begin to "sit up and take notice."

EXTRA DRY!

Kansas, the original dyed-in-the-wool prohibition state, is dry; yes, extra dry. Of course, it has killed business in Kansas to go dry and stay dry as it has. Here are a few figures that show how prohibition that is enforced has ruined that state:

In 87 of the 105 counties in Kansas there are no insane.

There are no feeble-minded in 54 counties.

There are no inebriates in 94 counties.

Thirty-eight of the county poorhouses are empty.

Fifty-three of the county jails were recently empty, and 65 counties could boast no contributions to the state penitentiary.

There are less than 600 paupers in the state.

Some counties have not called a grand jury to try a criminal case in ten years.

Recently Kansas had over \$200,000,000 in the banks.

The farmers own more than \$225,000,000 in live stock.

In one year the people have added \$45,000,000 in taxable property.

The mortality rate has dropped from 17 per 1000 to 7 per 1000.

Only 2 per cent of the population is illiterate.

William Allen White recently stated that Kansas had more college students per 1000 population than any other state, though a rival writer dug up statistics to show that Iowa, a neighboring state, and one that has rapidly "dried up" the past ten years, has this honor.

See what prohibition has done to Kansas!

A Cleveland daily of last week informs us that Kansas is the richest state in the Union in proportion to its population.

TEMPERANCE CAUSE—A NATIONAL DEMAND.

The temperance cause is not and cannot be narrowed down to any party, but is a national demand that overrides committees, politicians, and platforms and looks only to the individual invested with government. Hence we need now a healthy sentiment created that refuses to allow any party to try to monopolize our voters, but insists on every party affirming that "any alliance or combination with crime or criminals is repugnant to good government, and must be suppressed wherever found to exist." There is no standing still. We must move forward or retreat. Retreat? Never! We are listening for the clarion call of a new advance.

Bladen, Ohio.

C. H. CARGO.

ALCOHOL IN HOSPITALS; £23,000,000 FOR DEFENSE AND £180,000,000 FOR ALCOHOLIC DRINK.

Our long-time friend Herbert J. Rumsey, of New South Wales, sends us the clipping below from the *Daily Telegraph*:

A "DRY" HOSPITAL; DRINK AND DEFENSE; ALCOHOL NOT A VALUABLE MEDICINE.

Only £49 2s 6d was spent by Royal Prince Alfred Hospital in drink during 1914 on its 7237 in-patients admitted during that period. This works out at just over 1½d, or less than 1½d, per patient.

These figures were quoted with pride by Sir Thomas Anderson Stuart yesterday, who added that this satisfactory state of things was no rare phenomenon, being only the last of a similar series of years. There being 40 medical men on the staff entitled to prescribe alcoholic stimulants when they consider them necessary, it was clear that their low rate of consumption was not due to the fads or opinions of certain members of the staff, but must be the outcome of the practice of the medical men generally. The rate of expenditure was: 1884, 7s 9d per patient; 1894, 1s 4d per patient; 1904, 7d per patient; 1914, 1½d per patient.

This led Sir Thomas to remind his listeners at the annual meeting that there had been a growing conviction that alcohol was not the valuable medicine it used to be considered. In 1884, with 140 beds, the cost of stimulants was £715. In 1914, with three times the number of beds, it was only £49. And was not their mortality rate this year the smallest on record? Nor must they forget this, that 1½d worth was the average. Some patients who were very weak, such as recoveries from typhoid, had champagne—the majority of their patients never got a drop of alcohol in any form. He took the first hundred patients in the list. Of these 7 got alcohol 93 got none.

"Alcohol," proceeded Professor Anderson Stuart, "is a drug. In our hospital accounts it is included under the head of 'drugs and surgical appliances.' It is always as a drug that we should think of it. Speaking entirely personally, I might be permitted to counsel earnestly all who value individual and national efficiency to avoid the use of alcohol in any form, and in even the smallest quantities, except on

the written prescription of their medical attendant; for, as the events of the day in connection with the great war prove, it is the most soul-destroying, body-destroying, nation-destroying substance ever known. And yet since the inauguration of the Commonwealth in 1901, while we have spent 23 millions on defense we have spent 180 millions on alcoholic drink.

In regard to the standing of the physician who furnished the above statement, friend Rumsey writes as follows:

Dear Mr. Root:—Sir Thomas Anderson Stuart is not a teetotal crank, as some folks are apt to call us. He is a thoughtful man who considers every word before he speaks, and his opinion goes a long way here. He is Dean of the University, and the head of all medical-education matters in this state.

HERBERT J. RUMSEY.

Dundas, N. S. W., April 19.

The reader will remember the figures above are in pounds and not dollars, and hence should be multiplied by five.

ON THE BOOKSHELF

Practical Cement Work

By W. B. Henry. An elementary treatise on cement construction. The Concrete Age Publishing Co.

When a practical workman of large experience writes on his specialty for the direction of other workmen, his statements are usually thoroughly sound. This manual is of that nature.

Realizing that much of the information on cement construction is for the architect and contractor rather than the workman, and that what does concern him is often too technical for his comprehension, Mr. Henry has explained in the simplest form the facts which the man with the trowel should have.

The elementaries of cement chemistry, the history of its use, and directions for mortar and concrete making, precede the directions for work with foundations and walls, cement plaster and stucco houses, sidewalks, and floors.

This treatise is bound in cloth, contains 110 pages, and will be furnished by GLEANINGS IN BEE CULTURE for 50 cents a copy. The book, together with GLEANINGS for one year, will be sent to any address for \$1.15.

"The Model T Ford Car" is the title of a new book by Victor W. Page, intended primarily for the Ford owner who takes care of the car himself. It is profusely illustrated with good engravings from photographs, showing different manipulations and methods of dismantling the car for purpose of adjustment, and should fill a long-felt want.

The price of the book is \$1.00. Address the Norman W. Henley Publishing Co., New York City.

Honey Crop Conditions; A Queer Season

THE severe and prolonged drouth in southern Texas, cold chilly weather in the first part of the season in California, frost and freezing, and backward weather in Colorado and the mountain districts; too much rain and cold over a large part of the clover districts in the north central states where clover was promising; drouth in New York and parts of Pennsylvania, and unfavorable weather in the East, have had a tendency to put a damper on the hopes of beekeepers over all the country. In the mean time, conditions have improved in California, and some beekeepers have already secured a crop.

Up to as late as the 24th of June we have been having cold nights and cold, windy, sunless days. Clover was abundant in patches; but the temperature was too low for the proper secretion of nectar. Precisely the same conditions prevailed in many other localities where clover was promising. But now, fortunately, the continued spell of cold has been broken, and good honey weather is now on, and it looks and *feels* as if it would stay on. Our bees have taken a new start, and there is just a chance for us to secure some honey, as basswood was never more promising. In Michigan, Wisconsin, Minnesota, Canada, northern New York, and the New England states, this warm weather will probably come soon enough to catch all the honey that there may be in clover. In the clover districts further south clover has been out for two weeks, and there are good chances of a light crop, as there are at least ten days more of clover, with splendid prospects for basswood where there is any.

Taking it all in all, it is impossible to predict what the clover crop will be, although it is safe to say it will not be large, except, perhaps, in the more northern states.

Many reports speak of the immense amount of clover in bloom, while others say that it is very scarce.

We hope our readers, as soon as they read this, will continue to send in their postal-card reports. They are mighty helpful in making up these honey reports.

Prices should have an upward trend on all grades of honey, particularly on southern honey, which has been a failure in many parts of the South.

Those Patches of Yellow Sweet Clover Next to the Home Apiary

WHEN we let loose our carload of bees from Texas (referred to elsewhere) there was a perfect roar on the yellow sweet clover; and notwithstanding white clover and alsike were out abundantly, the bees seemed to prefer the yellow blossoms, although they worked on both.

Yesterday, June 22, the temperature was down to 60, with a cold northwest wind. It was cold this morning, the 23d, down to 55, and yet there was a sprinkling of bees on the sweet clover and alsike, but by no means as many as there were the day before when the temperature was up to 70; and when it is really hot there is a perfect swarm of bees going back and forth, for the yard is only a few rods away.

Fearing that we had overstocked the home apiary with a whole carload (there were already 150 colonies there) we moved 150 of the strongest to the outyards. Notwithstanding the home yard was apparently overstocked, we found that the outyard bees, when the weather was cold, were getting almost nothing, while the home bees that had this sweet clover were storing some honey.

As explained elsewhere the Texas bees arrived at Medina short of stores. At least half of them had only a dozen cells of honey when they arrived at Medina; and you just ought to have seen the way they jumped into this yellow sweet clover. When we moved the Texas bees to the outyards, away from the yellow sweet clover, they were down to the verge of starvation; while those

left at the home yard kept on storing from the sweet clover in spite of the fact that the temperature was down to 55. It was, therefore, necessary for us to feed at the outyards by a method which we explain elsewhere.

Unreasoning Prejudice against Bees, Cats, Dogs, etc., on the Part of Some Good People

SOME two weeks ago the editor of the *Rural New-Yorker*, Mr. H. W. Collingwood, inclosed a letter from a correspondent complaining somewhat of the attitude of the *Rural* because it recognized the valuable work of the bees in pollinating fruit-trees. This correspondent went on to state that bees were causing blight on his fruit-trees, and that they were a nuisance generally. We prepared a reply showing that, while bees might scatter blight, they do tenfold more good than harm in making more and better fruit, and that the damage they do to trees is not nearly as serious as stated. This reply appeared in the *Rural New-Yorker* for June 12. In acknowledging the receipt of this, Editor Collingwood, in his usual characteristic way, writes:

Dear Mr. Root:—I thank you very much indeed for your letter and for the article, which seems to me a very sensible one. I am glad to get this, as I think it puts it up to our readers just right. I find that people appreciate a good strong discussion of a subject, and want to have all sides of the matter brought out.

For some reason, which I have never been able to understand fully, we have a class of people in this country who have no use whatever for a "bee." Some people, as you probably know, vent a lot of spite on a dog. I know a man who hates a cat on general principles, and every time he goes out hunting he shoots every cat he can find, no matter whom it belongs to. I have another friend who, unhappily, thinks a child is about the worst nuisance that ever came into the world. I have seen him look at children, and I knew perfectly well that he was saying to himself, "Oh for the days of good King Herod!" and so there is no use trying to analyze these pet hatreds or pet abominations. Some men can see nothing about a bee except a very instructive word he carries at the end of his tail. They can appreciate his arguments in that line, and do not want to know anything more about him; and so I am glad to have our friend, the busy bee, have his innings, and I am much obliged to you for sending me to bat with a fair chance of making a base hit or a home run. One of them made a base hit on my little boy the other day, and the boy certainly made a home run for the house. He went back, however, as he now has a hive of his own, and he is getting to be something of a beekeeper.

New York, May 26.

H. W. COLLINGWOOD.

Mr. Collingwood strikes upon a point that is worth bringing out—the unreasoning prejudice on the part of some good people against certain useful animals. While we admit that there are useless curs that are a

menace and a nuisance to the public generally, there are some dogs that are invaluable. Years ago, when A. I. Root was raising garden truck and running a series of cold-frames and greenhouses, some big and little dogs persisted in walking over these cold-frames and breaking the glass. To him a dog was about as useless a thing as one could have on the premises. He was overrun with rats in spite of steel traps and cats. Much to his chagrin, the children got a little black-and-tan rat terrier; and he was a holy terror to rats. He kept so everlastingly after them day and night that he drove them off the premises; and for three years after his death, not a rat showed up. From that day to this, A. I. R. has had a most wholesome respect for some dogs, and particularly for that dog. He has always believed in good cats for catching mice.

Some of our friends the fruit-growers have a similar prejudice against bees. Some day they will wake up, like A. I. R., and discover that the very thing they once regarded as an enemy is, after all, one of their best friends.

By the way, if you have never read the *Rural New-Yorker*, you are missing something. Editor Collingwood's editorials sparkle just like the letter above. Moreover, he is a practical farmer himself. If you are interested in soil culture or in being outdoors, get acquainted with the man by taking his paper, and you will be the richer—spiritually as well as financially. There is hardly a journal that dares to expose humbugs like the *Rural*. It is an all-around paper, and, what is more, it has been a staunch friend of the bee.

Carniolans Hustlers and Early Risers

IN the earload of bees from Texas there were about a third of them Carniolans. After the bees had been released, the Carniolans were very much in evidence in the sweet-clover patch referred to elsewhere; and, remarkable to relate, notwithstanding there were ten times as many Italians in the yard as of the dark bees, there were as many Carniolans on the sweet clover as of Italians. The next bees that were much in evidence were the dark or leather-colored Italians; while the extra-yellow and the goldens were conspicuous by their absence.

Moreover, in the early morning, when the temperature was down to 60, the Carniolans were the first to go to the fields. Several of us noticed that, even as early as three and four o'clock in the morning, these black bees were going to the fields.

Mr. Wilmon Newell, who furnished the bees, has been breeding some very superior strains of bees, and among them were Carniolans. In fact, he has been conducting some valuable experiments in breeding bees, a report of which was given in a late bulletin from Texas. See GLEANINGS, page 214, March 15. That he got results is shown in the Carniolan strains at least.

Our Carniolans are now placed in out-yards by themselves, to prevent cross-breeding with the Italians. We find this particular strain very gentle, and regular hustlers. We have no Carniolan queens—only bees—so we cannot be accused of booming something for the sake of selling.

While we have somewhat opposed these bees on account of their swarming propensities, we are glad to say a good word in favor of any strain of bees that is not afraid of the cold, and that works early and late, even if they do have an inborn propensity to swarm in season and out of season.

The Arrival of the Second Car of Bees in Medina

THE second carload of bees arrived at Medina at 4 P. M. Sunday, June 20. Had they arrived on schedule time they would have reached here sooner by about twelve hours. They started from College Station, Texas, on Tuesday night, June 15, making four days and five nights on the road. The conditions at College Station were very unfavorable. High temperature and prolonged drouth had made it impossible to feed, and in consequence the bees before they started, or at least a good portion of them, were short of stores. The shipper, Mr. Wilmon Newell, asked us whether it would be practicable to feed the bees *en route*, as he found it almost impossible to feed on account of robbing. We advised against it, fearing it might stir up the bees, get them excited, and, being unable to discharge their feces, they would die before they reached Medina. As Mr. Newell, however, found it utterly impossible to feed before starting, on his own responsibility he directed our man to feed on the way. He furnished for the purpose several cans of thick horsemint honey from a locality where foul brood had never been known. With a large spoon or ladle this honey was spread thinly over the wire cloth of the colonies that were short of stores. Not enough was put on at a time to run through. This was done at intervals, and, contrary to what we had feared, colonies so fed came through in nice condition. The only losses were dead bees on the wire

cloth in colonies so strong that they died from excessive heat; for be it known that the car started when the temperature was 110 in the shade.

The method of loading the bees will be fully described and illustrated in another issue.

Carelessness in the Matter of Managing Foul Brood; Bees on Shares

WE have complaints from two or three beekeepers who have placed their bees in the hands of Geo. H. Kirkpatrick, of Rapid City, Michigan, to run on shares. It seems that the deals did not prove to be very satisfactory to any of the parties, and now they have complained to GLEANINGS that there has been unfair treatment on the part of the caretaker. After reviewing quite a mass of correspondence we are inclined to believe that Mr. Kirkpatrick, who was fairly successful before foul brood got into his territory, had all kinds of bad luck after the disease got started. At all events, foul brood developed among the bees in his charge, and the disease kept going on from bad to worse, with the result that they nearly all died. Two different parties complain that bees they placed in Mr. Kirkpatrick's charge contracted foul brood, and finally died so that they lost the value of their investment.

It appears that Mr. Kirkpatrick has had a great amount of sickness and death in his family. It also appears, if the testimony of reliable people can be believed, he leaves combs, honey, old hives, and frames scattered over the premises. That he has made an effort to cure foul brood among the bees put in his care, there can be no doubt; but no one can cure that disease and have his combs and hives scattered about in promiscuous heaps, as one of our reliable beekeepers who called on him testified.

One man, Mr. L. C. Woodman, put in the hands of Mr. Kirkpatrick a carload of bees. The former says that the following spring 100 of his colonies had starved in the cellar, notwithstanding in the contract Mr. Kirkpatrick was to feed 25 lbs. of stores to each colony. The expense of this was to be divided equally between them. Foul brood developed later, and things kept going on from bad to worse until all were dead. Mr. W. E. Forbes says he lost 100 colonies placed in Mr. Kirkpatrick's charge under similar circumstances. Still others have made like complaints.

While we do not believe that Mr. Kirkpatrick is dishonest, we cannot advise any one else to furnish him bees to be worked

on shares, in view of the reports that have come. No one can clean out foul brood unless he takes care of his old combs and hives.

Some three years ago Mr. Kirkpatrick had a beautiful home which he bought and paid for from the proceeds of his bees. We saw the place, and greatly admired it. At that time he had the reputation of being a good beekeeper; but in later years it would appear that foul brood, and sickness and death in his family, had materially handicapped him, with the result that he seems to have lost heart and grown careless. While we feel sorry for him, that does not excuse him for letting other people's property placed in his hands go to ruin.

If any one is going to put bees out on shares he ought to make sure that there is no foul brood anywhere in the locality where the bees are to be worked. Another thing that should be taken into consideration is that one who may be able to handle a small number of his own colonies with success may make a complete failure when he attempts to run the business on a larger scale, especially if he attempts to operate another's bees.

How to Feed Bees on the Verge of Starvation, without a Feeder, and do it with a Minimum of Labor

As explained, some of our outyards where we moved colonies that were short of stores were on the verge of starvation. If it would only warm up so the bees could get at the acres and acres of alsike clover, which was in the height of its bloom, no feed would be necessary; but it remained cold, and it is cold yet, June 23, although the Weather Bureau says we shall now have warmer weather. But it no sooner warms up a little than we have several days of cold. The result has been that one day we are expecting swarming as the result of a rush of nectar, and the next day we are expecting starved bees and starved brood. This morning, June 23, the mercury was down to 50. Examination of some of the hives at the outyards the previous night showed that some of the biggest colonies in the Texas shipment did not have half a dozen cells of honey. Something had to be done the next morning, and that right speedily. To see what we could do, we took along a can of very thick honey that we knew to be free from the germs of foul brood. We hunted up an old two-quart tin pail, bent one side of the rim so that it had a mouth or delivery like that of a coffee-pot. We filled this with thick honey, and proceeded to feed. A cold north

wind was blowing. An attendant opened a hive, blew some smoke over the top of the frames until he drove the bees down from the tops of the frames, or nearly so. We then took our little pail of honey, and poured a stream about a quarter of an inch in diameter. This stream we trailed lengthwise up and down the top-bars of all the frames. In other words, we made railroad tracks back and forth. These tracks were from a half to three-fourths of an inch wide. Sometimes they spread wide enough to run down between the combs and among the bees. If the colony was strong no harm was done. The work was done quickly; and as the honey was very thick, but little of it ran down between the combs. After feeding one colony we cut off the drip and went to the next hive. In like manner we went through the whole fifty colonies in about thirty minutes. When we got through with our feeding we found we had used a trifle over 50 lbs. of honey. That is to say, we gave each colony one pound of thick waxy honey without the use of a feeder or appliance of any sort save an old tin pail. A tin can of any sort will do just as well provided the rim on one side is made like that of a common coffee-pot beak so as to pour a small stream. When a colony is on the verge of starvation a pound of thick waxy honey is quite sufficient to tide it over until nectar from the fields comes in.

Of course this method of feeding is applicable only where a small amount is needed to tide the bees over until a flow from the fields comes in. In feeding larger quantities, regular feeders, of course, should be used.

When giving food in this way, care should be taken not to pour over the colony enough so that it will run down between the frames on the bottom-board. It might run out at the entrance, and start an uproar of robbing.

Precaution should also be taken to drive the bees down from the tops of the frames. While it would do no great harm to daub the bees with honey or syrup, it is best to avoid it if possible. A bee that has been smeared we do not believe is quite as good a bee after, even if it is thoroughly cleaned by its mates. If one will work carefully he need daub hardly a bee.

If the atmosphere is at all cool, lift the covers from all the hives. If there is a cool wind blowing, and the colony is not strong, the bees will quickly go down between the frames. Now is the time to pour the syrup over the tops of the frames, as explained, and then put on the cover immediately after each pouring.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

JOSEPH J. ANDERSON tried keeping colonies separate with newspaper, and failed, p. 500. Newspaper is not intended to keep separate permanently, but to unite, and for that purpose is a great success, as it no doubt was with him.

I'VE ALWAYS said that bees would put no honey in the super so long as there were empty cells in the brood-chamber. I'll never say it again. June 1 I found brood-chamber after brood-chamber destitute and a little honey in the super. But drawn combs were in the super. I suspect it's still true with only foundation in super.

A NEW MEXICO correspondent last year had 146 swarms from 200 colonies in 38 days, and asks what to do. Get all you can from the books (Fifty Years among the Bees is especially full on the subject), and then study out what best suits your case. If you dequeen a colony, and then in ten days give it a *young* laying queen, it will not swarm. Or, take away its queen, and at the same time drop in, without caging, a virgin less than 24 hours old.

HERE it is the middle of June, clover blooming abundantly, and bees on the point of starvation. Rain, rain, rain, cold and rain—don't know whether there's any honey in the clover; but from the way the bees work the few spells they can fly I suspect there is. But the prospect for a crop is not brilliant. [The same condition prevails here at this writing, June 21. The bees are going to the fields whenever it warms up enough. We may yet get a crop of honey, but it begins to look doubtful. Already the farmers are beginning to cut their alsike, which is our main stay; but fortunately they cannot cut all the alsike along the roadsides, nor are they going to cut down our basswoods—at least not this year. So we are waiting and hoping. This hope is the stronger because experience has taught us that *sometimes* our main honey-flow in the North comes after the first of July. Repeated rains in June, such as we have had this year, renders it not impossible to have the bulk of the honey in that month.—Ed.]

"DEQUEENING . . . may be sufficient; but it may be advisable to shake as well as requeen; and it may be necessary to shake again until the disease begins to lose some of its virulence," p. 480. That from the man who got me to dequeen instead of shake! I had experience with both shaking

and dequeening, in cases where European foul brood had not begun to lose its virulence, and it would take proof to make me believe that there is any case where it is either necessary or advisable to shake once, let alone twice. In American foul brood, yes; but never in European foul brood. Neither is it necessary always to requeen—never, unless a better queen can be given. Just stop brood-rearing for ten days or so. The bees will do the rest, although it may be necessary sometimes to repeat it. [It is true that we persuaded you to dequeen and requeen when European foul brood broke out in your beeyard. We do not remember whether we advised you not to shake or not. From the investigations we made at the time we were hopeful that requeening alone might be sufficient; and now you think we are inconsistent even to intimate that it may be necessary to shake as well as requeen. The statement in question was not a recommendation of ours, but a synopsis of a bulletin put out by Mr. Morley Pettit. The statement in question was his own and not ours, or, perhaps more exactly, it was an inference from his statements.]

We are glad to know that dequeening and requeening were sufficient in your case without shaking. Shaking, and melting the combs, involves a large amount of labor and expense. While the wax secured will practically pay for new foundation, it does not begin to cover the cost of labor in addition nor the loss and interruption to the colony if the operation be performed during the honey-flow. Shaking to cure foul brood, according to our experience, is always a setback to the colony, particularly in late summer or early fall; and as a general rule such a colony will go into winter quarters rather light, and will probably die before spring. It could not well be otherwise, as the loss of all the brood cuts the strength of the colony in two, and the half remaining are old bees that will die off rapidly. If, therefore, dequeening and requeening would suffice it would be a great boon to those who are suffering from European foul brood; but according to reports from the bulletin shaking as well as requeening may be necessary.

Elsewhere in this issue Mr. G. H. Kirkpatrick has tried to cure American foul brood, but has failed; but the evidence goes to show that he has not kept away the source of infection. Possibly some of those who found shaking necessary in addition to requeening are of this type.—Ed.]

BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado.

WEEDS AND BEEKEEPING.

The United States Department of Agriculture, Farmers' Bulletin No. 660, entitled "Weeds: How to Control Them," by H. R. Cox, names fifty of the worst weeds in the United States. The dandelion is one of the fifty, but sweet clover is not included.

Among the fifty worst weeds are found the following plants that are of interest to beekeepers: Dandelion, daisy, milkweed, mustard, and thistle. There may be other weeds among the fifty that furnish nectar or pollen, but I am not familiar with them.

HONEY CONDITIONS.

A very unfavorable season so far is what we have to record. Cold weather, freezes, rain, and cloudy weather have kept the bees from breeding. Most beekeepers are feeding still (June 12), and a lack of pollen has made feeding destitute of satisfactory results. Bees will have to have a good season in July and August or we shall be short in honey this year.

The most disastrous freeze of the season came late in May and ruined the early honey prospects from alfalfa. Sweet clover was set back, and the flow from fruit-bloom and dandelions was stopped.

The cold weather has prevailed throughout the Rocky Mountain region. Montana, Wyoming, Idaho, Utah, and Colorado all are served about alike. The freezing of the alfalfa was very severe in eastern Colorado, and not so serious in the western part of the state.

We have now had our ten inches of rain this season, and the precipitation of three inches above normal.

The Montana Beekeepers' Association has an energetic secretary in Mr. Percy F. Kolb, of Billings, Montana. The beekeepers of Montana have had such a varied lot of supplies and equipment that it was thought advisable for the association to establish standards; and in order to encourage the use of uniform goods to authorize the secretary to purchase supplies for the members. The secretary has done this, sending out several hundred price lists, and I am informed that over one thousand dollars' worth has been secured for the members on a co-operative basis. The Montana Association will doubtless gain a large membership in this way, and it is hoped that the

secretary will receive some pay for his time. The secretary of the average beekeepers' association has a lot of work to do for which nothing but the honor of the office is paid. Montana is a big and generous state. They do things that way. Montana is to be congratulated on having such a secretary, and Mr. Kolb is to be congratulated in having such a loyal membership.

Many of the alfalfa-fields in eastern Colorado have become infected with the black-stem blight, and the county agriculturists are advising prompt cutting to prevent permanent damage to the plant. The infection takes place where small breaks occur in the epidermis of the stem, due to the freeze; and, unless cut immediately upon detection, will follow the stem to the crown of the plant, which will finally die, leaving a poor stand in the field.

The first indication of this blight is a slight frost damage, all or part of the leaf turning yellow or almost orange. Yellowish, bruised-appearing places will be found on the stem in a few days, these later turning to an olive green and later still to a brownish color having a varnished appearance. The growth of the affected stem stops, and finally becomes black and brittle near the base.

This is, of course, of especial interest to beekeepers who hope to see the advice of the experts followed, as there are usually no frosts after the first cutting, and a healthy growth will be assured for the second crop. The first crop having been so badly frozen and bloomed there would be no nectar in the bloom should it appear in the first crop.

SPREADING BROOD.

I do not wish it understood that I make a general practice of spreading brood; but at the same time it is done with satisfactory results when carried on with other operations.

A number of my outapiaries become honey-bound, and it seems almost impossible to get the colonies to build up. In these cases uncapping a comb of honey at the side of the brood-nest, and putting it either close to the center or close on one side of the brood-nest, does relieve the situation. The place that such a comb is put in the hive depends upon its strength. By uncapping sealed stores, and spreading the brood by inserting these uncapped combs in the

Continued on page 527.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

The sad news of the death of Mrs. Acklin has reached me. I feel that I express the thoughts of her many friends when I say that a life that has filled a place worth while has passed. Such a life is not lived in vain. Mrs. Acklin was the editor of this department before the writer took up the work. She has been a recognized authority on bee topics for many years.

I am very much surprised at the remarks of Mr. Byer in commenting on my third note, page 353, May 1. He says: "Another mystery to me, surely! is it the strain of bees or what?" I am truly astonished that it is such a mystery to Mr. Byer. The appearance of laying workers is the most common way of which I have knowledge for colonies to degenerate, while drone-laying queens are a very rare thing with me. I do not believe I have had experience with more than a dozen careers.

Fertile-worker colonies are the natural sequence of the loss of queens in winter and early spring. Breeding during the winter months is at its lowest ebb. It is no uncommon occurrence to find a colony without brood at times. The failure of a queen to lay during this period causes no alarm among the hive force since there is no incentive for a queen to lay. Naturally those failing during this period are allowed to reach a state of exhaustion where it is impossible for them to lay. They die with the colony hopelessly queenless, since there are no eggs from which another may be reared. The colony remains in this condition until, as a last resort, a worker is chosen to perform the functions of a queen.

In the same issue, page 433, the editor comments on the situation as varying so widely here from what it is with Mr. Byer. In this he seems to have in mind that Mr. Byer is astonished that so many two-year-old queens disappear, while I take it that Mr. Byer is concerned that so many of my colonies have fertile workers. I have passed the point where I am concerned about the loss of a colony from the fact of its becoming a fertile-worker colony. I expect a certain percentage of them to have fertile workers where they are not annually supplied with a young queen. The loss with me from this cause where requeening has not been practiced reaches not less than ten

per cent annually. With young queens the loss is a negligible quantity. E. R. Root is entirely correct, however, when he says a queen's life in this climate is much shorter than it would be in the East where the queen is inactive during the winter months. But his surmise that I may have a sprinkling of Cyprian or Holy Land bees is wrong.

I wonder if it would be out of order if I should arise to make a few remarks about the much-discussed question of spreading brood, now occupying the minds of the editor and the department correspondents. Under certain conditions I am a firm believer in brood-spreading, but only under conditions prevailing with individual colonies do I practice it. However, it is profitable to observe the conditions of every colony to ascertain where it is safe to spread. To my mind there is gain in judicious spreading of brood in early spring, for an extra comb of brood early is worth much to the future of the colony.

But by the term "spreading" I have in mind not only the parting of combs to insert an empty one, but using other means to the same end. In our climate, conditions may be somewhat different from those in the East; yet my long experience there, and nearly as long in this state, has not shown me where a bee here differs from a bee in the East, save by her surroundings. Here in early spring I have seen two solid combs of pollen in a hive, one on either side of two to four combs of brood. This condition is deplorable from the fact that the pollen has checked the work of the queen. It must be removed or time lost waiting for sufficient bees to hatch to cover combs outside of the pollen-bed before laying can continue. In this case the pollen combs can be set out and an empty comb placed next to the brood, which is equivalent to inserting a comb between combs of brood. It does not endanger the brood in any manner.

Often where the side of a comb next to the brood-nest is pollen-bound, aid may be given immediately by simply turning the pollen side away from the brood-nest. When a colony has sufficient bees to cover more combs than those already containing brood, it is always safe to insert an extra comb in the brood-nest. The value of spreading brood is too great to discourage, and yet too risky to practice in a haphazard manner.

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

Thank you, Mr. Chadwick.

I was glad to see in E. S. Miles' article, page 462, June 1, that I am not the only one who gets nervous from the fear of squeezing the queen too hard, or otherwise injuring her when clipping. I shake like a foolish aspen leaf when I get started on that task.

Our first attempt to use the Fowls adaptation of the Alexander method of increase seems to have been successful. On May 9, finding queen-cells with well-advanced larvæ, we raised the entire brood-chamber to fourth place up, leaving one frame of brood and the queen below. The bees attacked the nine full sheets of foundation with energy, and in a week had several frames of drawn comb. On May 16 we removed the queenless brood from the fourth story to a new location, and on June 2 had two frames of eggs and young larvæ.

Among the "Interesting People" in the June *American Magazine* is "Honest Mose," Idaho's new governor, Moses Alexander. His is an interesting story, and, according to the account, he gives promise of giving the people of Idaho a good, clean, economical reform administration. But, alas that he should say, mentioning the needless expense that he intends to cut out, "It does not appeal to me to have such officers as bee inspectors. The people have certainly been stung enough already"! Surely some of Idaho's enthusiastic beekeepers will be able to show Governor Alexander the real economy of maintaining the office.

That dry April I commented on last month has been labeled by the Weather Bureau the driest in forty years. Headed by a dry cold March, it was tagged by a dry May—that is, till about the middle of the month. The clover came unusually early, hurried into an early maturity by the dry weather, we heard it explained, while the bees, retarded by the long-lingering winter, had been late in building up. That is not a happy combination. Then in mid-May, with clover in bloom, and a pretty fair force of bees, it began to rain, and "Sunny Tennessee" seemed as much a myth as Mr. Chadwick described "Sunny California" to

have been. For two or three weeks there was rain, cloudy weather, high winds, and the bees could not work. Several dark windy days I watched the few adventurous ones battling with the winds. It was right in their faces as they came back to their hives, and often sudden gusts forced them to make several attempts to alight at the entrance.

I kept wondering what the bees do when they are shut in that way for a week or more in the summer; but the weather that kept them in their hives kept me out. What do they do?

The locust flow was excellent, and the poplar good, though our own bees get only a little of the former, and, so far as we know, none of the latter. White clover is our main stay, and it is pretty fair. The rains may have helped it, though they came too late to give full value of good effect.

OF INTEREST TO WOMEN BEEKEEPERS.

Lifting is certainly the greatest problem for us. So far, in our own little yard, we have managed to do the hives with the heavy supers on either Saturday afternoon or Sunday morning, when Mr. Allen is here; but that is not always convenient, and we realize that we must work it out some other way, if I am to do the actual work, and our apiary increases as we wish it to do. Of course, there are the shallow supers to fall back on, though they mean more expense and more labor of putting frames together, wiring, putting in foundation, etc. I suppose we shall resort to them another year, however, if we don't have an inspiration in the meantime. Personally, I am greatly interested in the various articles that have appeared on the Long Idea hive, and I wish I knew a little more about the construction and manipulation of the one pictured on page 147, Feb. 15, used by Victor Vargas Gamallo, Professor of Beekeeping at Havana, Cuba. It seems as though such a hive as that might be manufactured as cheaply as the standard hive, as it does not require the large boards mentioned by the editor in that article, as a cost-objection against the Long Idea hive developed and used by Mr. Poppleton. I for one should like to be able to get into the brood-chamber without lifting off any supers. [We have an article from Mr. Poppleton going into the whole matter quite fully. This will appear in an early issue.—ED.]

Another question for us is, "Shall we wear gloves?" I have persistently declined, claiming that my hands could become hardened to stings as well as any other; but Mr. Allen contests that, as a woman's hands are less weathered and toughened than those of men doing out-of-door work, the hardening process comes too high, and he urges gloves. But I am sure the swelling is much less now than formerly, and I scarcely notice three or four stings, nor even six or seven. (We have one or two rather unmannered colonies that nearly always punish us.) So I have rejoiced in my increasing immunity, and scorned further protection than a veil. But now, like Mr. Chadwick (or, perhaps, more like Mrs. Chadwick), I view the sting proposition at a slightly different angle, and regret to admit I am still nervous from a recent experience. It happened when Mr. Allen opened one of the hives where I require help with the heavy super. I joined him just as he turned back to the hive, after setting the super off. The smoker was in my left hand; and as I was about to use it, but before I had a chance to do that or anything else, the bees jumped on me. Only three or four tackled the hand; but a small dark cloud dropped straight to my black-hosed ankles. Forty stings is a conservative estimate. I went to the house, replaced my low shoes with high ones, and came back intending to work; but by that time I was sick and dizzy. Soon I was in bed, my face flaming red, with the color extending well over the body. Strangest of all, though I scarcely felt the stings by that time, I was suffering almost unbearable external pain, and soon began shaking with cold. Mr. Allen called a physician; but by the time he arrived (perhaps half an hour

after the attack) the worst was over. In a few hours I was up, and that evening I took a long walk. But I am seriously considering a bee-proof uniform. The one pictured by the clever cartoonist of the *Backlot Buzzer*, June 1, is rather an inspiration.

The interesting feature of the occurrence was that this was the colony I had boasted of as being particularly gentle. But, you see, it was during the run of bad weather mentioned above, when bees are notoriously ill-natured (and justifiably so, perhaps), though we rather thought that day was near enough fair to open the hive to look for queen-cells. It had been eight days since the last inspection; and to wait another week for Mr. Allen's help might have been too long for good results.

EAGERNESS LINKED WITH CONTENT.

We love you, dear bees, for your quiet content;
You murmur and hum through the labor-filled
hours

At peace with the way the blown grasses are bent
And the touch of the sun on the flowers.

In rhythmical time, like a fairyland chime,
Recurrent and smooth as melodious rhyme,
Your spirit croons calmness to ours.

And, oh how we love you, brave bees, for your flight!
Though gauzy your wings for such journeyings
long,

You flash out and plunge into acres of light,
Exultant in swiftness and song.

A courage that sings—unhesitant wings!
You passionate, quivering, unafraid things,
What makes you so eager and strong?

If we all your simple contentment might learn

When straining hours clamor and press on us so,
And mount with your ardor where far visions yearn
When wearisome hours bring us low,

Awake and athrill, life's deep cup we should fill
With splendid achievement and quiet-wrought will,
Serenity, purpose, and glow.

BEEKEEPING AMONG THE ROCKIES — Continued from page 524

brood-nest, will often reveal the limits of the queens to the bees, and they will supersede her. In other cases these combs are filled with eggs and brood very quickly. Perhaps I would do just as well to uncap the combs of honey and leave them at the side of the cluster, but I do not think so.

The danger from spreading the brood in this way is in giving the bees more space than they can keep warm. This must be guarded against. Then it is useless to spread the brood if the bees do not very soon make the brood-nest one compact mass of eggs and brood.

Perhaps my method is not so much the spreading of brood as making the bees re-

move the honey from crowded combs and fill them with brood.

Many successful beekeepers practice methods that are of doubtful value. They get a crop of honey in spite of them, not because of them. The average beekeeper does not have time to test thoroughly the value of all the practices he follows. I may be mistaken in my fancied results from disturbing the brood-nest, but I don't think so. There are things that do stir colonies to greater activity, and I believe this is one of them. The practice of spreading the brood throughout a whole apiary I do not follow; but the individual needs of each colony are looked after.

NOTES FROM CANADA

J. L. Byer, Markham, Ontario

That statement of mine in the June 1st issue, concerning our early spring in Ontario, needs some revision at this date, June 11. While April was unusually warm, and vegetation came on in proportion to the weather, May proved to be one of the most backward on record, with cool days and some frosty nights; and as a grand *finale* to the unusual weather, a heavy frost on the night of May 26 killed tender vegetables and injured fruit in some places. At present we are in need of rain; and unless we get showers soon, clover will be very short. Bees are in fair condition, even if there have been but few days for gathering honey from spring sources of nectar, which all goes to prove once more that bees that have wintered well, and have lots of good stores to draw on, will stand a great lot of unfavorable weather conditions and yet build up for the honey-flow.

J. E. Crane, page 394, May 15, speaks of a weed called paintbrush, or hawkweed, that is such a nuisance in Vermont. North of Brockville, in Leeds Co., where we had a large apiary for three years, this pest is established firmly in the thin rocky and sandy soil that is common there. The plant seems to be good for nothing; but it will crowd out everything else unless, as he states, it is found that sweet clover will kill it. Judging from what I saw in Leeds Co. I formed the opinion that it would be only a pest in localities where pastures were left for years at a time; but it may be that it would establish itself in good land too. Personally I do not know the botanical name of the pest; but I remember the farmers calling it paintbrush, and all expressing a fear that it was going to ruin all their pasture lands.

Speaking of long confinements for bees during the winter, friend Doolittle thinks, page 441, June 1, that bees cannot be kept in for more than five months on summer stands and be in good condition for the summer's work. I suspect that would prove right in the majority of cases; but there are exceptions to all rules. When I wrote up the account of my trip to the yard win-

tering on aster honey, I did not care to be too sure as to how the colonies would turn out at that early date, April 7, and consequently kept on the safe side in saying how they had wintered. I am glad to say that they were much better than I stated in the May 15th issue. I have just returned from the yard a month later than above date, and, aside from some queenless colonies, not a single colony died, and we have no weak stocks in yard. Nearly all are fully occupying two full-depth stories, and some have three, with a clover-flow still ten days away. These bees did not have a flight from the last week in October till April 7, and the temperature was as low as 40 below zero. Another year might tell a different tale under like conditions; but as a rule we expect at least four months without a fly at that location, and with good stores we do no worrying.

That editorial regarding laying workers, page 433, June 1, does not clear up matters at all so far as I am concerned. Mr. Chadwick's queens play out and so do mine. So far all is plain sailing. Chadwick finds colonies that have lost their queens, with the majority having laying workers, and here is where the difference comes in. At the York Co. yards, owing to a total failure of crop last year, no requeening was done by me; and examination this spring shows that none to speak of was done by the bees themselves. As a result, although we had hardly any actual winter loss, yet fully 10 per cent (same as friend Chadwick's) are either queenless or might as well be so far as their usefulness for this year's crop is concerned. But in every case the colony is either hopelessly queenless with but a few bees left, has a young virgin that never was mated, or else has the old clipped queen laying a few drone eggs. Long seasons or many of them does not explain the difference, and it surely must be that Mr. Chadwick has a sprinkling of Holy Land or Cyprian blood as the editor suggests. I have been told by men who have handled these breeds that they are bad for developing laying workers. [Notice that Mr. Chadwick, in this issue, says he has no Holy Land bees nor Cyprians. Is it not possible that even pure Italians would vary greatly in this respect?—ED.]

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

WORKING FOR EXTRACTED HONEY.

"You are telling us all the time how to work for section honey. Can't you tell us something about the best way of working for extracted honey?"

In the late seventies and early eighties I produced much extracted honey, selling it for 15 to 20 cts. per pound to my neighbors, and I considered it profitable; but when the price went down, from various reasons, to 7 to 9 cents I concluded that section honey was more profitable. As to my way of working in those years, I find in an old diary some notes which I jotted down, giving the best way of working to secure a good yield, or one-third more pounds than I could of section honey from colonies of approximately the same strength. I have never fully carried out these plans, but I believe them worth trying.

At the beginning of fruit-bloom examine all colonies. From those that have brood in from seven to eight frames, and as many spaces well filled with bees, take one frame of brood from the brood-nest, selecting the one containing the most nearly maturing brood. Shake the bees off in front of the hive, and put a frame containing all worker-comb in the middle of the brood-nest, in place of the comb of brood taken out. Now put on a queen-excluding honey-board, leaving it on till the close of the season. The reason for taking this frame of brood from the brood-nest is that I find the queen will lay much faster in the middle of the brood-nest at this time of the year than she will in the outside combs. This being the case, right in the middle of the brood-nest is where we want the queen doing her work. What is wanted at this time of the year, or up to 30 days before our main honey-flow comes, is all the brood and young bees we can get. The frame of brood removed is put in an extracting-super directly over the brood-nest, and the super filled on each side with empty combs, or those having only a little honey in them. The bees go right to work in this upper story. If the weather is warm, and a little honey is coming in, I can, in a week or so, take another frame of brood from this same colony. This is put in the extracting-super beside the first comb of brood, taking out a comb that was beside the first frame of brood to give it place. As the bees have cleaned the combs next to the frame of brood first put in, and put a little new honey in them, such combs are just

right to put in the brood-nest in place of the brood removed.

Just a word of caution, especially to beginners: Be a little careful not to take too much brood early in the season from the brood-nest lest the queen and bees become discouraged. Our object is to stimulate the queen to lay to her fullest capacity.

In another week, take another frame from the brood-nest and exchange it for another of the cleaned combs from the super. Five days later take still another frame of brood from the brood-nest, but this time put it in another super and set it under the first, or over the brood-nest, destroying any queen-cells that may have been started in the first super given. This system of management is to be followed just as long as the bees emerging from the extra brood gained will be of profit to me working on the clover and basswood bloom. There is a certain time during the life of a colony, each season, when we can build it up faster than at any other time during the season, and that the bees from such building-up will be of double the profit to us that they would at any other time. With a ten-frame Langstroth hive worked in this way the brood in the brood-chamber and that in the supers may amount to 14 full frames, which, barring accidents, will put 75,000 field workers on the stage of action just as the flow of nectar from basswood bloom reaches its height. In 1877 such a colony gave me 22 lbs. of extracted honey for three consecutive days, and the result of the season from that colony was 566 lbs., enough remaining in the hive for successful wintering. Some colonies worked in this way gave one-third better results than did other colonies of equal strength that were allowed to take their own course. If I wished to run two or three colonies for comb honey, 15 or 20 days before the end of the honey harvest I took two or three of these large colonies and removed the two or three extracting-supers, and in their places put on three section supers. The bees will fill three about as soon as they will one. In less than an hour these section supers will be filled with bees and they go right to work. In this way I could take nearly as much section honey (even though late in the season) as I could if the colony had been worked for section honey from the beginning of the honey-flow from clover. The sections are so nicely filled that nearly all of them will class as fancy.

GENERAL CORRESPONDENCE

NON-SEPARATED HONEY—A CHALLENGE

BY ALLEN LATHAM

On page 616, August 15, 1914, the editor uses rather severe language regarding honey produced without the use of separators. Having produced comb honey after that manner for thirty years I wish to discuss the question.

If, *per se*, it were impossible to produce good marketable comb honey without the use of separators, the editor's position would be unassailable. If, on the other hand, good marketable sections can be produced without the use of separators, then the question should be debated on this issue—which system can be made to yield the better average results?

After an exhaustive use of separators, both plain and fence, I have practically discarded the use of separators as separators. I still use fence separators between the outer rows of sections and the super sides.

The one argument against the non-use of separators is divided into—

- (a) Sections lack uniformity of weight.
- (b) Sections cannot be crated on account of bulging combs.

As for (a) I state without hesitation that there is absolutely no truth in that notion. I have weighed thousands of sections from both separated and non-separated supers, and I can declare with certainty that there is as much variation in weight in the sections of one sort as in those of the other. Variation in weight is dependent upon other factors—the character of the honey-flow and the strain of bees. Only in the case of weak colonies can there be variation from other than those two factors, and such colonies should never be used in the production of comb honey. With such colonies the bees will work in only a few sections at a time, and will bulge the combs as they advance from section to section.

In the case of (b) I will admit that there will be more sections of non-separated honey difficult to crate than there will be of these produced with separators, but far fewer than most people are inclined to believe. In my own case the bulging sections are about offset by the leaky sections due to the bees fastening the combs to the separators. Here again the strain of bees is the controlling factor. One can as easily breed out the tendency to bulge combs as

he can the tendency to fasten combs to separators.

The difficulty with slightly bulging combs is not felt when cartons are used. All comb honey should be cartoned. When not cartoned it is exposed to the dust and germ-laden atmosphere of the grocery. We owe it to the consumer to carton our comb honey. All cartons should allow about one thirty-second of an inch beeway for easy withdrawal of section, and this is ample allowance for better than 99 per cent of non-separated honey. At times the slightly bulging comb will suffer some pressure, in which case there will be a patch of watery cappings, but seldom any leakage. There will, in fact, be far less leakage than will result from the broken cappings due to burr-combs in separated honey. Right here I should like to say that I have no use for a carton which does not completely cover the section. I regret the encouragement that the bottomless-topless carton has received of late. It is a poor makeshift.

Arguments for the production of non-separated honey are more than two:

- (a) It is less labor to prepare supers.
- (b) It is less labor to care for the product.
- (c) Bees more readily enter the supers.
- (d) Swarming is greatly lessened.
- (e) Honey is of better quality.
- (f) More sections can be put in a super.
- (g) A bigger crop can be produced.
- (h) Better for business.

All will, without debate, concede (a) and (b), and will readily agree that, if marketable comb honey can be produced without the use of separators, then the labor item alone settles the question. I think also that all will concede without argument that bees more readily enter a super of sections where there are no separators. A properly prepared super, put on at the right time, will do more than any other thing to keep down the percentage of swarming. Dismissing, then, the first four points in favor of non-separated honey I pass to (e).

It will surprise many that the claim should be made that better honey can be produced without than with separators. It is actually true, and upon two counts. Non-separated honey is better cured, and, as a rule, less waxy. The concentration of

work in one small apartment tends to cause the deposition of an excess of wax. This may account for the presence of burr-combs where separators are used. Foundation is not drawn out so thin where separators are used, and bees with wax scales do not find their way into another apartment so readily as they would to an adjacent comb. The honey is better cured in the non-separator super because there is more freedom for ventilation and the area of work is greater.

The next point (*f*) is worth careful consideration. Twenty-eight seven-to-the-foot beeway sections can be put where twenty-four separator sections would go, and thirty-two sections $1\frac{1}{2}$ inches wide can be put into the same space. It will thus be seen that in a large apiary there will be 15 to 30 per cent fewer supers used to produce the same number of sections than if separators be used.

As it is my experience that a colony will complete a 28 or a 32 section super without separators in about the same time that it will a super of 24 sections where separators are used, it will be seen that from 15 to 30 per cent more crop will be produced if separators are not used.

It is better for business for this reason: Probably the chief thing that keeps the old "manufactured comb honey" canard alive is separator honey. The casual observer will not note the slight difference in the sections of a fancy lot of separator honey, and will readily think that it must have been produced by machinery. The flat board-like finish stamps the honey as artificial. Non-separator honey, with its more or less wavy comb surface, is so obviously a natural product that no suspicion is aroused.

Such is my confidence in non-separator honey that I challenge the editor as follows: I will this season select a super of comb honey produced without separators, and send it as it came from the hive to Dr. Miller. The editor can do the same with a super of separator honey. Dr. Miller can pass judgment upon these two supers upon two counts only—crating possibility of each, and uniformity of weight of the individual sections. Color, flavor, etc., are not to count at all. These two supers can

then be sent to some orphanage or old folks' home, or a hospital, and the loser will prepay the charges.

Each super must be sent just as it came from the hive without sections being removed before the super reaches the judge. In case the season is a failure with either of us, then the challenge is to be declared off for the season.

Norwichtown, Ct.

[There is one element that enters into this controversy that you have not specifically mentioned; and that is, the man. Our argument as given on page 616, Aug. 1, 1914, was based on the kind of comb honey that had come from the average beekeeper who had tried to get along without separators. On that point it was not a question of theory but of actual fact. So far as we know, practically every honey-buyer in the country has concluded that non-separator honey is a nuisance, because there is not one man in a thousand who can produce honey in this way so that it can be marketed either in shipping-cases or cartons.

Our correspondent is an expert beekeeper. We venture to say that in the contest that he proposes he might win out; and that brings up the question: We should like to have him tell specifically how he can produce good comb honey without separators, and show us a picture, or several of them, showing a comb-honey super. Even after he tells us *how* he does it, we venture the assertion that most persons will make a bungle of the job, and the resulting comb honey will be anything but fit for market. However, we are open to conviction, and, like the proverbial man from Missouri, we are willing to be "shown."

In regard to his argument for the production of non-separator honey, we will concede without argument points (*a*), (*c*), (*d*), (*e*), (*f*), (*g*). Then there remain (*b*) and (*h*). If Mr. Latham is on the job of producing a product, we might concede (*b*); and if others can do as well as he does we will concede (*h*). After all, the whole question resolves itself down to the man and the method; but we put more emphasis on the former than on the latter. We shall await with interest Mr. Latham's article describing his method.—Ed.]

HONEY AS FILLER FOR CHOCOLATE CANDY

BY EDWARD HASSINGER

By cutting comb honey into cubes about an inch in each dimension, letting them drain on wire screen, and then coating them

with chocolate, just as other candies are made, one will have something that, in my opinion, is equal to the finest candy made.

Partial view of the apiary of Edward Hassinger, Greenville, Wis.

Granulated comb honey is the best for this purpose. I suppose extracted honey granulated can be used in the same way. With the ungranulated comb honey I have not succeeded in getting the chocolate, mixed with powdered sugar, to get hard enough for commercial purposes—perhaps because I did not give the comb honey time enough to drain dry. I suppose a professional candy-maker could get it just right. I have eaten chocolate drops with the inside filled with various liquids. I am sure extracted honey could be used in the same way. Well, just figure it out yourself. The possibilities are great in this honey-candy business.

PAINTING FOUNDATION WITH BEESWAX.

Arthur C. Miller has a nice row of drone-cells on the bottom of the comb shown on page 372, May 15, 1914. I have my foundation made to order, and have it made to fit the frame less one-sixteenth of an inch from each end-bar, and three-sixteenths of an inch from the bottom-bars. With the most perfectly wired frames there will be some sagging, or perhaps the foundation stretches a little below the bottom wire. Anyhow, a trifle more than $\frac{1}{8}$ inch space between the foundation and bottom-bar gives me the most nearly perfect all-worker

combs, including the bottom row of cells. I use only the medium-brood grade of foundation. If this is painted with plenty of beeswax all around the edges the bees will use some of this wax, and fasten the foundation to the frame all around, before they draw out the foundation into comb, providing, of course, the combs are drawn in the supers.

Your paint-brush for wax will work about ten per cent better if you will take two narrow strips of wood, a little longer than your brush is wide, and nail these together through the half of the brush, about in the center. At the same time, spread out the hair so your brush will be about one inch wider than it was before, and the hair of the brush will be all in a narrow straight line. This soon forms into a curve on the side that you brush the surplus wax off into your dish. Then use the opposite side of the brush against the curve for your first stroke or two on the foundation, and reverse the brush. With some practice you should be able to paint foundation without closing a single cell with wax, providing you have the wax at the right temperature. This you can learn only by experience.

Greenville, Wis.

BEEKEEPING IN THE BLUE RIDGE MOUNTAINS

BY J. J. WILDER

On account of poor transportation facilities beekeeping along the great Blue Ridge section of our country has developed slowly, and it is a great pity that such is the case, as it is so rich in honey resources, and much nearer our very best honey markets in the South. I have been along this great ridge of mountains for several hundred miles; and while much of it is very remote so far as civilization is concerned, yet I was somewhat surprised to find that our industry had not advanced any more than it had. As a rule this great and almost unbroken forest is full of bees, and the natives and visitors passing through this section never cut all the bee-trees, as they find they are so numerous. I have taken the lead in many bee-tree cuttings while spending the summers up there, and I have never seen bees in the forest in such good condition, such large swarms, and so much surplus stored. The honey in point of quality cannot be excelled.

Notwithstanding the poor transportation facilities, our industry has a great future there as soon as modern hives, conveniences, and methods are employed. In this way a few are becoming interested, and some have bought modern hives and are giving them a trial. I have seen only a few, and I never saw better - filled sections and supers. But log gums stand at nearly every mountaineer's home, and the illustration here shows an "ideal" apiary which consisted of over 100 colonies, all in hollow chestnut log gums, some very large and some very small, and all with large "heads" and heavy rocks on top.

This apiary is one of those owned and operated by the Lamb Brothers, who make beekeeping in this way their main line of business. I saw some of their other yards, but was unable to get good pictures of them. It was only after much climbing up a very steep mountain that I was able to get a portion of this one, which was on a knob

near the top of the mountain. The other wing extended around on the opposite side of it, with the honey-house and a great spring in the center. Where they got the idea of the honey-house I don't know unless an entirely separate place for the packing and keeping of it naturally suggested itself.

Not being able to see the owners I learned through their wives that they realized annually more than \$1.25 worth of honey per colony, which was hauled to distant markets in ox-wagons.

It will be seen that there is no natural shade for the bees, and that all about the hives is perfectly clean. They claim that shade is detrimental to the bees in that cool climate, and for best results they needed all the sunshine they could get. I asked if they had ever tried the "yellow" bees. They remarked that they had, but not with good results, as they swarmed too much, and the honey they made was too thin.

The climate in the mountains is so cool that shade is not only unnecessary but detrimental.

The strangest thing with me about the honey in these cold mountains is that it is always cool, even during the time it is being made, and the thin nectar will drop freely from the comb as it is being handled. The temperature in the brood-nest is very low, and hardly noticeable by the hands.

In fact, I don't see how bees even exist in trees down in the steep ravines under cool overhanging rocks where the sun never strikes them, winter or summer. Yet in

I take pride in seeing how neat I can keep the yard.

such places I have cut rich trees and obtained over 100 pounds of honey, and it is so thick and rich in flavor as to excel any I can find elsewhere in these qualities. The fault is overcome here naturally that we have to contend with in our extreme southern section where it lacks a body. For years I have been "pulling" my hives open in

view of more ventilation. Plenty of fresh cool air through the hives is the very best thing I can do toward the betterment of the honey. Had I not learned this by actual experience, the above would substantiate the fact that bees need air and not heat in a closed hive.

Cordele, Ga.

A FEW BEES AT THE CITY'S EDGE

BY H. E. HESSLER

Out of my 61 years I have kept bees 53 years. I believe that I was almost the first person in Madison Co., N. Y., although quite young, to purchase a Langstroth movable-frame beehive. I have never been in the bee business to make a living, but have always kept bees, and by some have been called a bee-fool. I would rather be called a bee-fool than some other kind of fool.

I have kept as many as 100 colonies and a little more. For the past 37 years I have been in the hardware and stove business at my present location, but always hung on to the bees. At one time I had thirty-five colonies on the roof of my four-story building where I am now doing business, and produced good crops of honey.

I did not dare to do too much extracting on account of being close to three churches, and, in fact, in a well-settled part of the

city. I have kept bees on city lots and had some little trouble now and then, but never anything serious. Generally the present of a little honey and good words settled up the matter. In a few cases neighbors who were very much against bees became interested and became beekeepers themselves.

At the present time I own a farm of about twenty-two acres, partly in the city and partly outside—that is, the city line runs through the place, which is known as Shady Side Farm. Here I have a very good place for the bees. I am not in it very heavily. I run about fifty colonies and take pride in seeing how neat and up-to-date I can keep the yard. It is mowed twice a week, and the lawn is as smooth as velvet.

The bees do not do quite as well, I think, as they would in poorer circumstances. I believe the bees realize that the master does

Not far away is the greenhouse.

not need their services. I am positively sure that this was the case last year, for in all my experience in the beekeeping business, last year I think was one of the poorest in this section, for gathering honey, that I ever saw, although I secured some comb honey, and put my bees into winter quarters in pretty good condition without feeding. Some of the beekeepers in this section did not do as well.

I use ten-frame double-walled hives. This present beeyard is directly opposite a large cemetery. There are a great many people

passing within a few rods—thousands of them. In fact, it is almost the same as being in the city—are lights, sidewalks, paved streets, etc. Many come into the yard and look at the bees, very often going nearer than they should with children. They go in past my beeyard, and within a few feet is my greenhouse where we sell flowers. I am yet to have a single complaint. My bees are thoroughbred Italians, but each one carries a sting just the same.

Syracuse, N. Y.

SOME INCONVENIENCES IN A BEEKEEPER'S PARADISE

BY S. M. CAMPBELL

This is the beeman's paradise, but, of course, there is always some "bitter mixed with the sweet." We can go out in a big orange-orchard and look across waving fields of green leaves and ripe oranges and see trees that have five or six bushels of golden fruit. Just above them on the mountain-side we can see pure white snow. Early in the morning, when the sunlight makes this glisten and sparkle, and the oranges gleam with gold, it is indeed a beautiful sight.

When the orange-trees are in blossom one can shake the trees, and the "honey" will come down just like a shower of rain. It is not honey, of course, but nectar as thin as water, for it takes about five gallons of

the raw nectar to make one gallon of ripe honey. The bees evaporate the honey out of it and make it thick and delicious.

There are about 30,000 colonies of bees in this county, and the output is about ninety carloads of honey yearly, nearly all of which is shipped to eastern markets. Ventura County is mountainous, as, in fact, is all of this part of the state. The mountains vary in height from small hills up to mountains thousands of feet in height—some of them ten or twelve thousand feet high.

We had quite a trip last summer to one of the outyards about fifteen miles up in the mountains. A party of us started one morning about nine o'clock. Our "boss,"

Mr. R. M. Spencer, was with us on that trip. The only way one can get to this yard is on horseback, so horseback we went, and it was the hardest trip I have ever taken, to say nothing of the dangerous experience. There had been 23 inches of rain, and all signs of the trail had been destroyed. We had to wind our way up a river over big rocks that lay in great piles, some of them as large as a dwelling - house. We were getting along nicely, and had gone about six miles, when suddenly, without the slightest warning, our horses whirled around. Just in front was a rattlesnake six feet long. Mr. Spencer was in the lead; and when his horse whirled the saddle turned, and he was thrown to the ground squarely on top of the snake. He probably owes his life to the fact that the snake was uncoiled, and was probably as badly scared as the members of our party. Mr. Spencer was sure "on top" that time. We killed the rattler, and went on up between the mountains over some places that were so steep that we had to get off and lead the horses.

We finally reached our destination and found the bees in bad condition and the hives scattered all over the yard. A black bear had been there and had destroyed about 30 colonies. Apparently the bees had stung him, and he had slapped the hives to pieces in a number of instances. We straightened up the hives that were left, stayed all night, and started for home the next morning.

On the way home Mr. Spencer was again unfortunate. Crossing a bare steep rock his horse slipped and went down, and he was thrown into a hole with the horse on top of him. We rolled the horse out and finally rescued our boss. We had some trouble,

This is the plant that A. J. Root found growing in a field of red clover; there was also common sweet clover in the same field. After spading up around the plant he threw some grass and weeds around it, as you will notice. See page 358.

believe me, but reached home at length, and the boss is here yet.

At another time we started for this yard with three days' provisions of canned goods. After a tedious ride we finally reached the yard and found there the same old story. There had been another bear, and 54 of the colonies were destroyed. About two o'clock that day it began to rain. We were rained in for several days, and we had to cut our bill of fare down to two meals a day, and these, of course, were very small in order to make the food last. You may be sure that we cut those slices of bread very thin.

The cabin was in a safe place, however, and there was about 400 pounds of honey

Three leaves of the common sweet clover and also three from the new plant pictured on the preceding page. These leaves are shown about three-fourths life size. See if you have any sweet clover growing in your vicinity with leaves as large as those on this new plant. See page 558.

which we decided to melt up and have it ready to feed the bees when the storm was over. The honey was granulated, and we had a time of it. This was good "man feed," too; but one gets tired of honey only, on a long stretch.

The empty cans had been thrown outside, and during the night we heard them rolling

around. The next morning the cans were scattered all over everywhere, and it was plain to see that a bear had been there again. Bears like honey too.

It was five days before we could cross the creek, and then we had to cross about twenty times.

Nordhoff, Cal.

STEEL STAYS FOR SUPPORTING BROOD-COMBS: A SUBSTITUTE FOR FINE WIRES OR WOODEN SPLINTS

BY B. F. AVERILL

My experience in wiring frames for staving foundation began in 1879, when I first used comb foundation. I had tried the flat-bottom foundation with the wires incorporated in process of manufacture, and its utility failed to meet expectations. The idea occurred to me that *frames* should be wired, not the foundation. So I ordered a spool of wire and found the wired frames more satisfactory. I used three horizontal wires, 1, 2½, and 4 inches respectively, below the comb-guides.

In 1882 I accepted a managing interest in the South, with the late Paul L. Viallon, of Bayou Goula, La. The wiring problem there was a labor of some magnitude, and the plan of wiring in vogue was quite expensive—a folded tin brace in the center

between the top and bottom bars—eight perpendicular wires and two diagonal brace wires from the center of the bottom-bars to the corners at the top-bars.

Suggesting to Mr. Viallon that I could devise a method of staving foundation in brood-combs that would be more economical and sufficiently substantial he requested me to bring out something, saying he would be glad to find a plan that did not require quite so much patience and skill.

I gave an order for some splints 8½ x 1⅜ x 1-16, sawn from section stock, and put up a set of foundation and frames the next day. In a day or two I had a swarm hived on them, and a week later a set of drawn-out combs as pretty as I had ever seen.

Mr. Viallon pronounced the innovation

Our field of biennial yellow sweet clover. This was cut the latter part of May, just before it began to show indications of bloom; and although the hay remained out in almost half a dozen showers, and it was nearly two weeks before we could get it dry enough to store in the barn, our cows and horses prefer it to anything else; and the amount of cream and milk was quickly in evidence as soon as the cows got a taste of it. While I write, June 16, the field is one mass of yellow blossoms roaring with bees. To-day I went out through the clover-field pictured above. To my surprise I found patches of alsike clover of wonderful luxuriance scattered through the sweet clover, and both are in full bloom and humming with bees. But there were at least a dozen bees on the sweet clover to one on the alsike; and although I spent quite a little time watching the bees I was not able to find a single bee that worked on the alsike and also loaded up on the sweet clover, and *vice versa*. It was a pretty good demonstration that when a bee starts to gather honey it confines itself to one particular plant, and does not gather a little from one blossom and then get some more from a different plant. There may be exceptions to this; but in that clover-field, where there is a great plenty of bloom of both alsike and sweet clover, each busy worker seemed to have its own job and stuck to it. See Gardening Department.—A. I. ROOT.

an excellent idea, and said they were suited for general utility; but he could not make a departure from standard methods. With his shipping business of full colonies and nuclei such a change off hand would be almost too radical for consideration.

As soft lumber was used for these splints, results might not have been satisfactory. The bees gnawed the splints between bottom-bars and combs. Some of them were cut off entirely.

Here the matter rested until I was situated to use the splints upon my own responsibility. Four years later I was located in Bolivar Co., Miss., with a couple of apiaries of my own, and I had fully tested my method with splints in the mean time.

I used them there two seasons—1500 L. frames, and did not have a comb in the whole lot showing any imperfections. But these splints were sawn from oak lumber, and the bees did not gnaw them as they did the softer splints sawn from basswood in Louisiana. The bees do not gnaw the splints in the extracting-supers except in the brood-combs; and with splints of soft lumber combs are often much disfigured in the center of the brood-chamber. With oak, or lumber as hard as oak, the wood splints are, perhaps, equal to wire in durability.

Getting splints sawn from hard material was a difficulty, and I decided to pay the

additional cost, and use stays of soft steel wire. In 1907 I ordered 10,000 wire stays, and put over half of them in service. So far I have not regretted so doing.

Some years ago I wrote an article describing in GLEANINGS my method of utilizing wood splints; and the same principle of application is correct for the wire stays. Inquiries having come to me then for further particulars, and thinking a picture might make the plan more explicit, I am illustrating four frames, numbered for a brief statement of their serviceability.

No. 1 is a frame showing the nine wires full length, as I generally use them. It is best to use a drop of glue at each end of the center wire. No. 2 is a frame with half-length wires as I used them for half-sheets of foundation. A call for hives, when I was putting them out on shares, and being short of foundation, was the occasion for using half-sheets to secure straight reinforced brood-combs.

The frames with half-length wires give ample support for full sheets of foundation; but for transportation before being worked out by the bees, the wires should be set in place with glue. By general adoption the double groove and wedge can be discarded, saving a strip of foundation the length of sheets in any dimension used.

Contact with the top-bars is requisite;

Stays of soft steel wire are superior to wood splints.

and foundation is so soon fastened when thus placed that no defective work is possible by the bees. With the center wire glued at the top and bottom, no sagging of foundation has ever occurred. When not glued, there is sometimes a slight sag of the bottom-bar, but never any enlarged cells caused by stretching of the foundation.

No. 3 represents a drawn comb; No. 4 a sheet of foundation as set up when placed in the brood-chamber or super. It will be noted that the wires in frame with foundation are placed on alternate sides. This is unnecessary as the adhesion is as perfect to the wires as when the foundation was set up in 1907.

The comb and foundation have been exposed to the changes of humidity and temperature since the cycle of three unproductive seasons, beginning in 1907; and out of all examined I found the foundations as firmly fixed to the wires as when they were first rolled down. In rolling, the wire should be underneath. This advantage of adhesive durance cannot be claimed for the 30-gauge wire now in general use. I have never known frames wired with this small wire that the apiarist did not have to recomb frequently where foundation had not been given to the bees. Especially is this the

case with foundation put in frames in the fall, and not drawn out before winter.

The advantages of the method described are the saving of half the time, and doing a job that will stand, and the saving of 175 inches of foundation in each 100 pounds used—175 inches in width, and the length of the combs used in the apiary.

The initial expense of wiring by the method described exceeds the usual cost by the present plan of wiring; but the saving of labor and foundation where the grooves and wedge are not used, more than offsets the added cost entailed by using the 16-gauge wires for perpendicular wiring.

As the bottom-bars in the illustration do not show any grooves I wish to explain that the wires engage in the groove $\frac{1}{8}$ inch deep. In the top-bars, the grooves may be deeper. The comb and foundation, as shown, is in the frame with $\frac{3}{8}$ -thick bars, and the depth of the grooves is $\frac{1}{8}$ inch, top and bottom. On splints and wires I have never used wax. The queens would lay in the cells with wire at the bottom a little more readily at first if they were waxed; but after a few broods of bees are hatched in the combs these cells are not avoided by the queen in preference to the others.

Howardsville, Va.

On a hill facing southeast, the apiary is well protected from cold northwest winds.

A HILLSIDE APIARY

BY OSCAR RITLAND

Our apiary is located on a hill facing southeast, where it is well protected from the cold northwest winds. In addition to this, during the spring months the hives are wrapped with tarred paper to prevent unnecessary escape of heat. On May 6, 1914, 91 per cent of the colonies had five frames or over of brood.

It is a nice thing to have an apiary located on a side hill, provided it is not too steep. When the grass is wet with dew one's feet are liable to slip and cause no end of trouble. For this reason, if it is too steep, it would be advisable to locate under a bill.

One can save space by locating the hives in pairs. If it is desirable to use the Alexander method of building up weak colonies one can set the strong ones alone at first. Then when it is time to separate the two, the one on top can be set down beside the other side, thus becoming its partner. If the entrances are set on each side of where the old entrance was, each will receive part of the flying bees.

I have had the trouble that, when one hive was moved to a new location, too many of the field bees went back.

Elroy, Wis.

THE MINNESOTA SHORT COURSE IN BEEKEEPING

BY FRANK C. PELLETT

It was my good fortune to spend two days at the short course in beekeeping at the University of Minnesota in January. It does one a world of good, sometimes, to get away from home for awhile to see what the other fellows are doing. I feel very sure that the short course was a surprise, even to the enthusiastic fellows who are respon-

teous, assured the beekeepers that there was no demand for anything of this kind. They were mistaken, as they are now able to see. Under the leadership of the association president, John Doll, and the secretary, Dr. L. D. Leonard, they went before the legislature and asked for recognition. Not only did they ask that beekeeping be taught, but

At the University of Minnesota the interest in beekeeping is unflagging.

sible for the advanced ground taken in Minnesota.

The department of beekeeping is recent history. The beekeepers' associations of that state have been asking that beekeeping be taught in the university along with dairying and other lines of agricultural activity. The university authorities, while cour-

they demanded that it be given the same consideration offered other branches, and that a separate department be organized.

It seems surprising that great universities should so often have to be led, instead of leading, as they are designed to do. The legislature granted the demand of the bee-men, and the department was established.

Prof. Francis Jager was selected to head the department, and entered upon his duties only about two years ago. The choice seems to have been a very fortunate one, for Prof. Jager has the most loyal and enthusiastic support of the association and the beekeepers generally. A substantial increase in funds for the department for the coming two years is provided for in the University budget.

The big surprise, not only to the college officials and to the general public, but to the beekeepers as well, came when, at the short course recently held, the class in bee-

keeping was larger than any other in the entire university. Seventy-eight persons registered for the course, and nearly one hundred were in attendance at some of the classes. The interest was unflagging, although Prof. Jager was kept busy with classes continuously from eight in the morning until five in the afternoon, some days.

When the college officials of other states, or members of the legislature, tell the beekeepers that there is no demand for anything in our line, just point to Minnesota.

Atlantic, Iowa.

WHO PAYS THE FREIGHT?

BY J. M. DONALDSON

We were passing a large grocery in the city when we noticed a very fine display of comb and extracted honey. The comb was in Danzenbaker sections, and would all grade "Fancy," price 25 cts. The extracted was a good grade of light honey, and was put up in a very neat container. It was also 25 cts.

I said, "Bill, it's not often you see as nice a display as that."

"That's true all right; but do you know I don't blame the city chaps for not using more honey? The price of those sections is not so bad; but when it comes to paying 25 cts. for a jar of extracted like those, then I renig. My honey was much nicer than that, and all I got for it was 7 cts. I don't think those jars will hold more than 12 oz. of honey. They are marked 11 oz., and they are cheap at that price. Have you any idea of what it costs to put up a package like that?"

"No, I have not; but with your experience you should. Now listen, Bill," I added, "the fellow who bottled those goods probably paid 7½ or 8 cts. per pound to the beekeeper. Now, before he could set his selling price he must add to the price of his honey, freight and carting charges, the price of his bottles, corks, caps, labels, and packing-cases. Then there comes the wages, rent, insurance, business tax, and interest on money invested. He must also make allowance for bad debts and breakage. Bottlers are not in business for their health; so he must figure on a little profit. After the bottler comes the jobber, then the retailer. They get their profit. There in the window are the goods, waiting for Mr. Consumer to foot the bill."

"I will admit that, when you take those things in consideration, I cannot see where

there is as much profit on those goods as I thought there was; but here is what sticks me—what sense is there in using such a costly package? Why not use tin buckets or Mason jars? Then they could give the consumer more for his money."

"There are several reasons. Just look in that window. There are sauces, pickles, jams, jellies, meats, and even fish put up in fancy glass jars, and some of the jars cost more than the goods they contain. You know that a great many people choose their food, first by looks, then come quality and quantity. Fancy packages are what they demand, and those you must give them.

"There is another reason why you could not use Mason jars or tin pails. Grocers will not handle packages that are daubed with honey, nor do they want it granulated. Those jars are sealed air-tight, and are never sticky. The honey will remain liquefied for a long time."

"How is it that you can sell honey that way if the grocers can't?" he inquired.

"That is easily explained. I am selling direct to the family trade. My honey is consumed before it has time to granulate. Then I explain to each new customer that honey will granulate, and why it does. I also tell them to keep it in a warm dry place."

"Say, Donaldson, be honest about this; can't you sell a little cheaper than you do? At 50 cents a quart, allowing you 5 cts. for the jars, that leaves you 15 cts. a pound for the honey, and you know you could not get that price if you sold wholesale."

"I know that," I replied; "but let me tell you that when I have to bottle honey and retail it at wholesale prices I'll quit the business and devote my time to something that will pay. If I do the bottling and re-

Two characteristic views of the honeybee on white clover, the first showing the bee in the air about to alight on the blossom; and the second, taking the nectar from the outside. Note the path or motion of the wings in the first picture—wings at rest in the second.

tailoring I consider that I am entitled to the profits. Of course, my expenses are not as heavy as the city bottler and retailer, so I can split the difference with my customers, giving them more honey for their money. There is a more important reason for charging the price I do.

"If you are going to cater to a family trade you must be able to supply it every year and all the year. You cannot supply it when you have a crop, and let them go when you have a failure. Where would I have been this year if I had been retailing at wholesale prices? I did not harvest one pound of honey; and when I should have been piling on supers I was feeding from three to four hundred pounds of sugar to keep the bees alive, and living in hopes that the fall flow would put them in condition for winter. Last season was a bumper crop, and I had quite a lot left over, but not nearly enough to supply my trade.

"Now you see where the bottler and retailers' profits come in, don't you? They put me in a position where I can buy and sell at a profit, and hold my trade too.

"Now, Bill, you have been telling me of things you don't understand, so here is one for you. When my honey began getting low I sat down and wrote to sixteen beekeepers who were advertising honey for sale. I asked them to quote their price on honey delivered at their station, the sale to be cash with the order.

"I received twelve replies, and every one of them asked from $1\frac{1}{2}$ to $2\frac{1}{2}$ cents per

pound more than the market price. What kind of business do you call that?"

"Well, I should say it was mighty poor business, with the emphasis on the poor; but where did you get the honey you are selling now?"

"I get it from a packer. It is very nice too. It's a blend, but it just suits my trade because that is what they are used to."

"Don't you suppose I could sell quite a little honey where I live? If you can buy and sell at a profit, why can't I?" he queried.

"How doth the little busy bee,
Improve each shining hour!"

"You can if you do a little talking. Since you asked that question I must tell you a little joke, and it's on you too. I was over to your town last week and made quite a few sales. I sold to eight families on the street you live on. When you go home to-night ask your next-door neighbor (Mrs. Gaskill) how she likes Donaldson's honey."

"Look here, old man; you are getting too fresh," Bill exclaimed. "I am going to make it my business to see that you don't do that again."

"Well, that's business. See that you don't forget it."

If beekeepers would devote as much time and study to marketing as they do to producing a crop, there would be less cause for

grumbling about the market price of honey. There are many who live in thickly populated districts who, with a little effort, could retail their honey for much better prices than the market quotations; but instead of doing so they keep on shipping into the cities, paying freight, commissions, and cartage. When their returns come they will growl about the difference between what they received and the retail price.

I often wonder if such beekeepers ever stop to consider what the added cost of honey is, from the time it leaves the apiary until it reaches the table of the consumer in the cities.

Moorestown, N. J.

BUSY BEES OF BEEVILLE

BY J. W. TAYLOR

We have worked up from five colonies in 1884 to about eleven hundred at this time in eighteen apiaries, all of them two to sixteen miles from this city in nearly every direction. We work our queen nuclei up to full colonies to winter, and start new ones every spring. I, my son, and a hired man take care of all the work in connection.

We work for bulk comb and extracted honey, and we have made a specialty of breeding for the best honey-gatherers.

Beeville, Tex.

Mr. and Mrs. J. W. Taylor.

BEES AND THE YOUNG IDEA

BY J. L. GRAFF

A colony of Italian bees has been installed in the biological laboratory of the high school at Holland, Mich. The bees are to become an object of study to the biological class during the whole of the school year.

They have been hived in a case with glass sides, and during the bloom season they will be located at an open window so that they may go and come at will.

The study will be in charge of a young woman teacher who is informed on bee culture. It is a movement that should interest

not only every apiarist in the land but thousands of people who should be eating honey if they are not.

It is particularly interesting to all Michigan, the land of bloom, and to the people of other states in which there is an increased spread of crops that afford work for bees and profit for their owners.

The experiment at Holland is being watched by varied interests, among them the men and women who appreciate the pollination agency of the honeybee.

Chicago, Ill.

AN ELECTRIC BARREL-FILLING INDICATOR

BY G. W. HAINES

When I started in beekeeping as a business I soon learned it was a hard dirty job, as well as a rather expensive one, to allow a honey-can to run over. So I rigged up the scales at each apiary with an electric bell to ring every time the scale-beam raised.

The weight was set to equal that of a full can. When the beam raised the bell rang and shut down the honey-gate. This worked to perfection for several years; but since my apiaries have outgrown the small cans I could not set a 600-lb. barrel on the scales. I soon found the old trouble. About 25 lbs. of honey would run down over the barrel and over the floor.

I sat right down and said to myself, "I will have a bell on that barrel." I got through the season by running over two more barrels. During the winter I made an electric outfit for each apiary. It hooks in the bung of the barrel, set in the hose or funnel. When the liquid gets to within $2\frac{1}{2}$ inches of the top it raises a wooden block or cork, working on the same plan as a battery

switch, making a connection, and the bell rings. A heavy cord hangs over the extractor, attached to the blades of a small switch and to a hole bored in the end of the handle of the honey-gate. When the bell rings I pull on the string. The switch stops the bell ringing, and shuts down the honey-gate. Then I change the barrel for an empty one. I have several honey-tanks that hold a ton each. I hook an electric device made a little differently from the one for the barrel to the top of the tank. When the liquid is about four inches from the top it raises a wooden float-block, makes a connection, and rings the bell. I have spent considerable time looking to see if a tank was full. You all know it is well worth \$2.50 to clean up about 25 lbs. of honey spread over the floor.

The outfit requires a roll of wire, electric bell, dry cell, small switch, and the device for the barrel or tank.

Mayfield, N. Y.

CHUNK HONEY ADAPTED TO CAFETERIAS

BY THE OUTLAW

It is a matter of common knowledge that bees do their best when the cluster is least broken up. The ordinary comb-honey section has this fault of breaking up the cluster. Sections also have to be bought in quantities, and there is also the expense of the furniture for the supers. In my own case with one colony of bees hidden away on a roof, it naturally follows that the idea of purchasing sections and making super furniture did not appeal. I might also state that I have a natural aversion to paying out real money where satisfactory results can be obtained without making any investment. The solution was to have the surplus honey stored in ordinary shallow frames made from the wood of boxes in which the city grocer is in the habit of delivering groceries.

In my own apiary during the past season my one colony of bees, besides being increased to three colonies, produces for me approximately 150 pounds of honey, and the only outlay was the few moments' time it took to make the frames and supers from the material just mentioned. The average weight of such frames was between three and four pounds. It is not the claim here that such frames of honey are superior to

sections, but I do claim that such frames of honey can be produced with but a very small fraction of the time and trouble involved in producing honey in sections; that, if properly manipulated, more surplus honey can be produced; that the honey is much more conveniently handled; and that the small amount that such city apiarists have can be just as readily disposed of as if it were in sections.

In place of having to expend real money for sections and fixtures, whose initial cost will amount to the value of the crop received, his expenses are nothing. Such frames of honey as a present to your friends (and here I speak from actual experience, having disposed of about 30 per cent of my crop in this way) are preferred to a section; the reason being, perhaps, that a section holds a scant pound while the frames hold about four times that amount.

At first I was a little bit dubious about being able to dispose of such frames of honey, as the average grocer having become accustomed to honey in sections would not take kindly to such cumbersome frames, neither would the average person who has become accustomed to buying honey one section at a time care to purchase as much

honey at one time as such frames contain. In fact, the thought of disposing of such frames at any regular market, or the thought that such a market existed, had never occurred to me until one noon, while making the daily round at lunch time through the food avenue of a cafeteria I noticed that among the desserts resided a row of saucers, each of which contained a portion of comb honey.

I could see no special reason why a cafeteria should desire honey in sections, and so took the matter up with the manager. He said he would as soon have the honey in such frames as I had as in sections, and

willing to take whatever amount I had, and pay the same price per pound as he was in the habit of paying for sections. I might further state that, from my observation, the cafeteria here on the Pacific Coast has been to a certain extent neglected. Probably only about one in three of the large cafeterias is in the habit of keeping comb honey as one of the desserts. Apparently a little missionary work is necessary, and if some live salesman took it upon himself to do a little work here in the cafeteria belt of the Pacific Coast it ought to result in the developing of a good healthy market.

PUSHING HONEY SALES WITH ADVERTISING

BY JOS. BRUNSTEIN

I came to this blessed country on July 7, 1913, and, knowing beekeeping, I found a job where I worked hard to get acquainted with American systems. When the season was finished I lost my job, owing to my leaving to take up a homestead. Coming back to Denver I could not find work, so I

ed to peddle honey at groceries, with a capital of \$100. It was hard to induce some of them to keep honey, as they told me they had no demand for it; but in time things looked better. I gave to each grocer display cards, and promised to exchange the candied honey for new. Before Christ-

I worked hard to get acquainted with American systems.

went to a honey firm and asked the manager to allow me to solicit orders for them by the retail trade on a commission basis. He explained to me that they are doing more of a wholesale trade, and he could help me by selling honey which I might resell to the retail trade.

I began to investigate; and, seeing that there was a chance to make a living, I start-

mas I inserted small advertisements in the newspapers, like the following: "If you want to have a sweet Christmas holiday, order a gallon of Puritas honey, which will be delivered to you." I got some orders from it too.

But I saw that the Denverites are more used to the canned syrups and molasses, and were consuming honey like a drop from a

big barrel. On this account I began to look for ways to get them more acquainted and interested in what honey is.

Putting an advertisement in the Sunday edition of the *Denver Post*, one of the largest and most popular papers in Colorado, I got as a premium for my paid advertisement a saucer. Later I learned that this paper is giving away on each Saturday from 4000 to 5000 premiums for paid advertisements in the Sunday paper.

I went to the business manager and had a talk with him. He was busy, and told me to call the following week, and so on; but I kept coming till I had a chance to talk it over more freely, and to give him a jar of honey to taste. He promised to give me a chance, and I was satisfied with this inter-

view, as I knew he would like it. The next week I got an order for four thousand jars of honey.

In this way I accomplished something more than by advertising in the newspapers. The reason I did not advertise more was the lack of capital; but, as experience taught me, honey is not advertised as much as it ought to be. This could be very easily accomplished by some writers in giving to the editors of big city papers and country newspapers, home journals, and magazines, articles on the honeybee, and how honey is produced, making nice little stories of it.

Next fall I hope to sell more honey, and the summer I shall spend with the little creatures.

Denver, Col.

JOLTS AND JOTTINGS

BY E. F. ATWATER

GLEANINGS for Jan. 15 touches on a number of items that interest me, and so I give a few points gained from experience.

In Dr. Miller's Straws it is quoted that, in labeling glass, we should put the paste on the glass. We have labeled thousands of bottles for honey, and can beat that for speed. Simply buy gummed labels—no paste to make, no time to waste, and they stick. It is only on tin, which is usually a little oily, that there is any trouble.

Don't rely too much on combs fresh from the extractor not being moth-eaten. They may not be completely consumed, but they will sometimes be ruined. Even full combs of honey are not safe.

In his last Straw Dr. Miller says, "Please, Mr. Editor, don't say a V starter in a section is a satisfactory compromise. It's false economy. The bees will fill out with drone comb; and unless you use excluders, the queen will go up and fill out your sections with drone brood."

For many years Dr. Miller has qualified the above assertion by saying that the queen would go above unless there were plenty of drone comb below in the brood-nest; but it seems that queens are becoming less circumspect, and now will naughtily go above anyhow—except in this locality.

Dear beginner and respected veteran, use a half-sheet or V starter with a bottom starter, if you must economize; for in my experience and observation not one queen in a hundred, on the average, will go above to lay, regardless of the presence of drone comb below. We have used hundreds and probably thousands of supers with a con-

siderable gap between the two starters. Most of the extensive producers whom I have visited do the same, either regularly or at times when they run short of foundation, and there is very little trouble. With the increased use of ten-frame hives it is even less probable.

Of course many seasons such a plan may not be true economy; but even that is a question in the West, with its 10 and 12 per cent money.

Some very careful experimenters, extensive producers, doubt the advantage of full sheets in the sections; and while I am not among them, yet they get very good results.

In Mr. Crane's Siftings reference is made to the new way of making chaff division-boards. Could not oiled corrugated paper, cloth covered, be used?

In Mr. Holtermann's excellent article, mention is made of the use of tartaric acid to prevent granulation of syrup. Some have reported failure with its use; and in this connection, I have understood that the object of the acid is to secure partial inversion of the sugar, and that inversion does not take place so much by the mere presence of the acid as by being boiled with the acid for some time. It is possible that, by so doing, the syrup will much more nearly approximate honey in its composition, and be far less liable to harden in the combs.

In Mr. Baldwin's article reference is made to the old plan of rolling a queen in honey for introducing. I have had an occasional failure, even by this method.

In Mr. Wilder's article on Caucasian bees it reads a little queer to be told at the last

Prominent beekeepers of New Zealand were present.

that he has over 1000 colonies of pure Italian queens and that he will add to them. With all the advantages claimed for the Caucasians, why should Italians, even though excellent, be tolerated?

In regard to Mr. Miles' article, "Fighting the Ant Invader," I have been quite successful by running an iron bar into the nest, sprinkling a gallon of coarse salt in and on the nest, and throwing a pail of water over it. The ants usually leave before long.

In Heads of Grain Mr. I. Langstroth asks for reports on ventilated escape-boards. They work as quickly as any, and are very satisfactory.

Mr. J. S. White gives his plan of wiring, which is substantially what we call the

"Chantry method" here. We drive a $1\frac{1}{4}$ nail through the top-bar, and bend the end to make a hook to which to attach the vertical wire. We have thousands of frames so wired; but unless waxed over where the wires cross, bees may gnaw a hole there, which may not afterward be filled.

This plan stops sag in the middle, with splints necessary; but I may abandon it, as it is not adapted to electrical imbedding.

I agree with Mr. O. Bromfield in his condemnation of splints, after using tens of thousands of them. If one can get perfect combs built over them, they are O. K. used in five-inch lengths in connection with wires; but—there's the rub.

Meridian, Idaho.

FIELD DAY OF CANTERBURY BEEKEEPERS

BY E. G. WARD

The annual field day of the Canterbury Beekeepers' Association was held on Feb. 20 at Dr. Pairman's apiary, Governor's Bay. About fifty people attended. The weather was ideal, and the trip by motor boat was thoroughly enjoyed. Prominent beekeepers were present from other districts, and addresses and demonstrations occupied the time profitably.

Mr. L. Bowman, government inspector of apiaries, examined a hive which had been treated for foul brood by Dr. Pairman on lines similar to the Baldrige method. The treatment was found to be successful.

A paper by Mr. W. E. Barker on "The flora of New Zealand in relation to the honeybee" was much enjoyed. It showed how valuable the native flora is to the beekeeper.

The president, Mr. E. G. Ward, gave a short address on the aims and objects of the association, and appealed for contributions of honey in aid of the poor of Britain and Belgium.

Mr. R. W. Brickell, secretary of the National Beekeepers' Association, was present, and gave a detailed account of what was being done by the National Association to improve the conditions existing. He ex-

A wild spineless cactus found in Texas and Mexico, showing both fruit buds and slabs. See p. 556.

Common cactus growing wild near Laredo, Texas, and also over the line in Mexico. See page 556.

plained the details of the contract entered into between the Bristol and Dominion Producers' Association and the New Zealand Honey-producers' Association and the Government regulations dealing with the export of honey. The contract insures that a minimum of 100 tons and a maximum of 500 tons of honey be guaranteed a market for a period of three years at a satisfactory price. The local market will be relieved,

and much better prices realized in consequence.

Mr. A. Ireland explained what the Canterbury Association had done to help the movement during the last three years, and did some energetic canvassing for the co-operative association.

After the customary votes of thanks to the host and hostess the party left for home.

St. Albans, Christchurch, N. Z.

THE DARK AND BRIGHT SIDE OF FOUL BROOD

BY G. C. GREINER

In recent years the subject of foul brood and its treatment has been so many times and so thoroughly discussed that it almost seems like a waste of time to say more about it. The only excuse that might justify a reopening of the subject is the fact that the experience of passing years brings out occasionally new features—something that has not been spoken of before. At the same time the constantly enlisting recruits in the reading circles of our bee-periodicals, who had not the privilege of following up these discussions of former years may look for just such information.

Before I had the misfortune to fall a

victim to that dread disease the simple word "foul brood" sent a thrill of terror through my veins. Although I was prepared for the combat; had read everything our bee-magazines had published for years on this subject; had studied the bulletins sent out by the Department of Agriculture of New York; had new clean hives with the necessary outfit on hand, and had ordered my queens, still the uncertainty of the outcome, whether foul brood could be successfully eradicated or whether it meant the end of my occupation as a honey-producer, was anything but pleasant. But since I passed through the ordeal four years ago, and since

Another view of the common cactus showing a growth higher than a man's head. See page 556.

I have found by experience that the foul-brood trouble is not as serious as it appeared at first, I look at these things in a very different light. It is an easy matter for the alert beekeeper to keep the disease under control. In spite of being surrounded by foul brood we can raise as good paying crops of honey as we did before the disease made its appearance; and I go even one step further, and say we can raise better crops than we ever did.

To keep control of the disease it is necessary that the beekeeper know the condition of his bees at all times. This requires constant watchfulness and inspection. Bees must be examined at regular intervals; and by doing so he may see things that require his attention which otherwise would be passed unnoticed. Although I have great faith in Italian queens as foul-brood resisters, they are not positively proof against it. Now and then a slight attack will reappear, and every queen that allows the least indication to take a foothold in her colony should be replaced by another, either home-bred from the best queen in regard to honey-gathering proclivities and immunity from the disease, or else purchased from a reliable dealer's guaranteed stock. This in turn will have a tendency to improve our

stock, and consequently increase our crop. Slightly affected colonies of Italian queens can be cured by the caging process; but the disease is liable to reappear again, and for this reason it is safer to supersede them with more reliable stock.

To say that foul brood is a blessing in disguise may be a little exaggerated; but there is certainly one good point about it. It has a tendency to clean out some of these one-horse concerns generally termed farmer beekeepers. They are no benefit to the honey industry. In some out-of-the-way place along the backyard fence, hid by grass and weeds, they keep a few colonies of bees, expecting to raise a little honey for their own table. In the spring, or during a honey-flow, they may supply their bees with the surplus appliances they consider adequate for the season; but after that they pay little or no attention to them. They are never examined, and are left to fight their own battles. If they are free from disease, well and good; if not, just the same. For all the owner knows, his bees may be rotten with the disease, weakened down to a mere handful, or possibly gone entirely, and their hives a prey to the robbers of other apiaries. Thus they become a constant menace to neighboring beekeepers who are trying to keep the disease among their own bees under control. This state of affairs may not be entirely the fault of these farmer beekeepers. They do as well as they know how and as their situation permits. Just at the time bees need the attention of their keeper the most, farmers need every minute of their time to see to their haying and harvesting or other necessary farm-work, and it is only a natural consequence that their bees have to be left to shift for themselves.

In the fall they gather up whatever their bees have accumulated in the line of surplus honey. Frequently, in favorable seasons, it is more than they need for their own table, and the surplus is taken to the market, where it again becomes a menace to the professional honey-producer. Not having the time or ambition to prepare their little crop properly it is brought as it is taken from the bees. Unsorted, uncleaned, and unprotected it is placed with a load of garden truck in an open wagon. Dust and dirt have free access to the honey; and by the time it arrives at the market it is anything but an inviting, appetizing morsel. Not knowing anything of the ruling market price, and their fear of not finding ready sale for it, they offer it at two, three, and even five and six cents below the price properly put-up goods would demand. To a

certain extent this establishes a lower market price. I have had people call at my wagon, and, after inquiring the prices of my goods, would say: "You ask too much for your honey. Your neighbor down the line asks only so much."

As I never do any bantering, but uphold my established prices, I generally advise them to buy wherever they deem it the most profitable. Some, of course, leave me and go back to that cheaper neighbor; but the majority, who are observing enough to notice the superiority of my stock, would pay my price.

Annoying as it is to have these outsiders tamper with a business they do not understand, their slipshod management does not seriously interfere with my plans. I do not wish to be selfish, nor deny others the privilege I enjoy. On the contrary, I am always willing to let others profit by my experience. As far as I am able I am ready to assist by word and actual demonstration

whenever I am called on to do so; but for the benefit of the professional honey trade, to raise beekeeping to a higher standard, the cleaner the sweep the better.

As an additional foul-brood report I will say my bees were free from the disease the first two years after the treatment. A couple of stray black swarms that had taken possession of empty hives the following year developed the disease in moderate form. Their queens I promptly superseded with Italians, which cured them permanently. Last summer I again noticed three slightly affected colonies—at least I suspected them. I applied the different treatments to all three. To one I gave a new queen. The queen of the second I caged for ten days, and four brood-combs of the third, that showed the least indications, I moved into their extracting-super. All were cured for the remainder of the season.

La Salle, N. Y.

WHERE STIMULATIVE FEEDING DOES NOT STIMULATE

BY E. S. MILES

I don't like the term "stimulative feeding," since to me it seems misleading. My experience is exactly like Dr. Miller's. When the bees want brood, and have honey on hand, they will feed what they have, even if nothing is coming in; but, of course, if none comes for a sufficiently long period, brood-rearing will slack off and finally cease altogether. Bees appear to distinguish between fall and spring; hence when the final stop to gathering comes in the fall they seem to know that stores may be more important than a few more bees. Unless there is an abundance of honey on hand they may let some brood perish.

Let me try to tell how my bees do in spring. When first set from the cellar all queens will lay a patch of eggs, even if nothing is to be gathered. If there is old pollen and honey in the combs these eggs will be hatched and the brood reared. If there is an abundance of old pollen and honey, the queen will keep on laying until she has all the brood the bees can protect on cool nights. Now, so long as my colony is in this condition nothing can be gained by feeding; so it follows that the phrase "stimulative feeding" is misleading.

My bees will always do as outlined above; and if I had any that would not I would surely part with them and get some that would. But suppose no stores come in, and the first brood emerges, the colony gets

stronger, and can cover more brood. That is something I have never known; for, within the time of setting from the cellar, and the first brood emerges, there always comes bloom enough of some kind to furnish some new pollen and honey. The coming of additional stores allows the bees to enlarge the brood again to their capacity for keeping it warm.

Of course, if one prefers he may call this gathering a "stimulation" and be correct; but it should be borne in mind that there is "a time for everything under the sun." If we had the condition suggested above, where the colony could cover and mature more brood, and if more were desirable, and if pollen or a substitute were available (notice the ifs), and if old stores were running short, what would we do? I would feed. To stimulate brood-rearing? Well, you could call it that if it makes you feel better; but I say to myself, "The bees are running short of stores; they are becoming economical; and if I let them practice economy *now*, may be I'll be compelled to do so later."

So I practice what I call "doping 'em up." Put on a feeder and feed them till they feel rich and fat—that is, unless I am morally certain a flow will start up within a day or two. In such a case I feed them enough so that, if I were in their place, I wouldn't worry if I thought it would rain

for two or three days. Now, what will be the result? The queen will immediately enlarge the brood to the ability of the bees to cover, as at first, and the bees will mature the brood so long as there is no need of feeling economical.

Why not a little warm syrup every evening, after the good old orthodox way? Well, that's all right with a few hives or one yard, if you would prefer doing it a little at a time and just at dark, so the bees will not fly. But if you have more than you can feed at dusk, why make every colony go through the excitement, wearing themselves out trying to find something every time you feed? Save time and bees by "doping 'em up" all they will need at one feed. What if you give them too much? Well, in my locality, with my bees, that would be just right.

You'll be surprised at the way it will be turned into brood in the spring. Of course, now, you know that if a good flow from

fruit-bloom, willow, or if clover is likely to yield soon, you wouldn't "dope 'em up" so heavily as to have syrup left to go into the supers—no danger, probably, of this before fruit-bloom; for with plenty of room the right kind of bees will use up any surplus of stores after fruit-bloom and before clover.

To recapitulate: In the spring bees will mature all the brood they can keep warm, if they have plenty of stores. If they run short enough to cause a slacking off of brood-rearing, give them feed, and give them plenty of it, for best results. If you wish to call this "stimulative feeding," good, although the idea should not be entertained that the brood-nest can be enlarged indefinitely in early spring simply by a little feed given regularly. Dr. Miller is undoubtedly right in holding that this idea in the head of an inexperienced person might do more harm than good.

Dunlap, Iowa.

INDIANA NOTES

BY S. H. BURTON

Prospects for a honey crop are anything but encouraging in this or "Hooppole Tp., Posey Co., Injany." The cold backward season has retarded brood-rearing, and bees are very light in stores. It looks now, June 1, as if I would have to resort to feeding—a condition never heard of before in this locality.

White clover is just beginning to come back. Patches of it can be seen along the roadside, and a few blooms scattered over the meadows. As predicted in a former article, it will be some time before this section of the country produces any white-clover honey.

Bees have worked freely on yellow poplar between showers; but the rainy weather has spoiled the prospect from that source.

I am in love with the gray Caucasians. They are unquestionably the gentlest bee I ever handled; and as to breeding I will say you just ought to see a colony that was started five weeks ago. A queen was put on two frames of Italian brood with about a pint of bees, and to-day that colony is nearly as strong as any in the yard. I have opened it many times without gloves, veil, or smoke, and have yet to receive the first sting from them. After handling a cross race of Italians that will fly at my hand by the hundreds when passing it over the brood-frames, it is a pleasure to work with the gray Caucasians.

What is it worth to transfer a colony from a tree into a hive if the owner of the tree falls it for you and helps cut the log open?

There are a good many drawbacks to the Alexander plan of making increase. It is conducive to swarming, and fails to attain the desired end at times. I have had bees refuse to start queen-cells in the upper story with the queen confined below.

The plan I like best is to divide the colony, placing the nuclei on the original stand with or without the queen, and placing the original colony beside it. After both are started again nicely, remove the old colony to a new location.

I don't like brood-frames made from California redwood. The wood is too brittle to do a neat job of wedging in foundation, and the wood is inclined to sliver and split easily.

Washington, Ind.

Intensive Farming

They used to have a farming rule
Of forty acres and a mule.

Results were won by later men
With forty square feet and a hen.

And nowadays success we see
With forty inches and a bee.—EX.

The Backlot Buzzer

Ain't much to say under this picture other than to just let 'em swarm.

Shipping Bees to British Columbia

According to the terms of one of the classes of our foul-brood act, all bees imported into British Columbia are quarantined for nine months at the point of entry. The transportation companies, to protect themselves from a lot of trouble, refuse to accept bees for delivery in British Columbia. Shippers in the United States and Eastern Canada will find it wise to turn down all orders from this province.

Queens in cages are admitted at present, but every beekeeper has been advised to buy only from breeders who can show a clean bill of health from an inspector.

To-day British Columbia has fully one thousand beekeepers, mostly beginners on a small scale; but as the inspectors become acquainted with its immense territory they begin to believe that the province will at no distant date march into the front rank as a honey-producer. Our government is guiding the efforts of every one in the industry, and our progress is very rapid. We cut down our importations of honey last year by 58 per cent, and trebled our home production. Our primeval forests are literally full of honeybees in the settled districts, so there is no excuse for anybody wanting to import from other regions.

The inspectors' job is to keep this huge area free of foul brood. We have had four attacks in five years, all traceable to imported bees. I am fighting the last and most serious. It originated in the city of Vancouver from imported queens, and was carried to a couple of other points by unlucky purchasers. Last fall I found American foul brood in 20 apiaries, affecting 45 colonies, all of which were burned.

We make no pretense of curing the disease in British Columbia. One diseased cell condemns the hive to the flames. Now that I am in the fight I endeavor to trace the spread of the contagion, as all information is valuable. Here is one point I discovered: In one apiary of five colonies I found one affected. The nearest diseased colony, a strong one, was fully two miles away. The affected colony was also very strong, having been a very large first swarm. After some close questioning I found that the hive-body had been bought from an infected apiary where it had been in use for a week swarm just three weeks. The frames were new with full sheets of foundation. Advocates of the "shake" system of cure will kindly take notice.

As I see it, the essence of this plan is a pure gamble. You despoil the bees of all their combs, stores, and brood, and chance that about 99 per cent of the germs are in the plunder. Then you hope that the germs on the bees and hive will never get an opportunity to enter the anatomy of a bee baby. We in British Columbia are just as anxious to wind up the career of the hundredth germ as the other ninety and nine. One of our inspectors in one apiary found that the spores must have lain dormant three years before their opportunity arrived; for the hive, brought from an infected region in Oregon, had been in British Columbia that length of time before foul brood developed.

F. DUNDAS TODD, Foul-brood Inspector.

Victoria, B. C., Canada.

A Simple Feeding Device

I have always been trying to devise some slow but sure automatic way to feed for stimulation since Mr. E. W. Alexander described his stimulative feeding in his bottom-board feeders. I wanted something that would feed very slowly but continuously night and day, and something that could be used in out-yards so it could be carried right along by only going to look after them once in a week or two.

This spring I broke the lining from the inside of a Mason fruit-jar cover, punched a tiny hole from inside in the center of the cover, and put on rubber and cover to make the jar air-tight except the hole punched.

To prepare the hive for the feeder, remove the cover; pick out the center of the cluster if the weather is cool; replace the quilt, and spread on top of quilt several thicknesses of newspaper. Now punch a hole through the quilt and papers between two frames right above the cluster, about the size of the end of one's finger; invert the jar, and set over all the empty supers, and cover. You see there is no space between the feed and the cluster except the thickness of the jar cover, and all the feed is delivered automatically at that tiny point.

All it costs is the cover, which lasts a lifetime, and jars can be used for canning purposes if not in use. The glass jar shows how much feed is in the feeder at a glance. There is no rust, no rot, no leak to this feeder. Try one feeder on your pet colony, and see if these thoughts are not worth the cost of GLEANINGS one year.

Colo, Iowa.

D. E. LHOMMEDIEU.

Dampening Sections

I take as many sections in my hand as I can hold tight; hold them under a small stream of water; wet them on both sides just where to be bent. A gallon tin can full of water with a nail-hole near the bottom will do.

Acequia, Idaho.

MRS. I. B. TITUS.

The National Net-weight Law Does Not Apply to Shipments inside of State Boundaries

I wish a little information in regard to the net-weight law in regard to honey. I sell my honey by the case, nothing being said about weight, to a retail grocer in my own state. Will it be necessary or desirable to stamp the net weight on each section? That is, can an inspector interfere with it unless it is billed to another state? Suppose I were to send a package of honey to a person in another state as a gift, would it have to be stamped? This seems to me a strange law. It is all right for packages that man fills and can put in a certain amount; but I can't see why it should apply to honey any more than to apples, oranges, or eggs.

Arcola, N. C., April 28.

R. B. HUNTER.

[The national net-weight law does not apply to local sales made within a state. You can sell honey at your local grocery, or send it clear across the state anywhere without marking the net weight on the individual sections nor upon the case itself. In a few states laws have been enacted that are in conformity to the national law, but we do not know of any state where it is required to put the net weight upon sections of comb honey.]

You are right. It ought not to be necessary to mark the net weight upon the section of comb honey where the weight varies so, any more than it should be necessary to mark the net weight on each individual hen's egg; but on all interstate shipments it is absolutely necessary, to comply with the federal law.

If you send a case of honey across the state line as a gift we don't know that the law would apply; but we would advise you to mark the weight upon each section, or, perhaps, better, mark the minimum net weight, and then grade the sections according to weight.—Ed.]

The Variation in the Color of Italian Drones from Different Queens

Why will one Italian queen produce all yellow drones and another one all black drones?

Which are the best drones to mate from—the yellow or the black?

Which are the purest leather-colored stock—the yellow or the black drones?

I purchased two queens last summer, the first in a full colony. This queen's drones are all yellow. Her bees also show some yellow.

The second queen I received was in a five-frame nucleus. This queen's drones are all black. Her bees show a darker color than the above (or first) queen.

Young queens mated from these black drones produce dark-colored bees, some very dark, almost black. Jacoby, La., May 31.

R. L. LINDSEY.

[Italians are not a fixed race. Some strains are yellower than others. The yellower the bees, the yellower will be the drones as a rule, although there are exceptions to this. Drones of leather-colored queens are generally dark; while drones of goldens are quite as yellow as the bees themselves. In the case to which you refer, you probably purchased a queen of the golden order the first time, and the second time a leather-colored queen. It is possible that the second queen was not pure. If such were the case, and you bought a tested, you should send samples of the bees to the breeder, and ask for a replacement. But bear this in mind, that the queens of drones produced from leather-colored bees show almost no yellow, and sometimes none at all; but such drones (if the mother was pure) will produce fine gentle Italians that will probably show two dark yellow bands, and a third one somewhat indis-

tinged, and very often not at all until the bees are filled with honey. The color of the drones is not as uniform as the color of the workers. This means that judging a queen by the color of her drones is not always reliable.]

It is evident that the leather-colored Italians come the nearest to being a fixed race. They are more uniform in their general markings—that is to say, they vary less as to the color of drones and workers. They are generally good honey-gatherers, hardy, and uniformly gentle. These Italians are raised on one or both sides of the Alps, and through centuries in a vigorous climate, in high altitudes, and are, therefore, a strong race. The extra yellow Italians are raised in southern Italy or in Sicily. They will not stand our northern winters, are irritable, but are well adapted for a southern or a mild climate.—Ed.]

Does Honey-dew Granulate More Readily than Ordinary Honey?

Does honey-dew honey ever granulate? My bees are bringing in a honey new to me. It granulates before they can get the cells filled. It is not very dark, and tastes very well. How can I get the sugar out of my extracting-combs for the next honey-flow?

Havana, Ala., May 29.

J. S. PATTON.

[Strictly speaking, honey-dew honey is not honey, and is not so regarded by the Bureau of Chemistry, Washington, D. C. If, therefore, it is not pure honey it might not granulate quite the same as ordinary honey. So far as we know, honey-dew honey does not granulate more readily or more quickly than ordinary honey; but that it does granulate there can be no doubt.]

Of course, it may not be honey-dew honey that you have. There are some kinds of honey that granulate very rapidly, almost as soon as they are stored in the combs.

We would not advise you to have it taken out. If the bees get plenty of water they will utilize it in brood-rearing. It may be advisable for you to dampen the combs containing the granulated honey. If you find the bees carrying the granules out of the entrance of the hive we would advise you to do this, but hardly think they will carry it out.—Ed.]

Mating before Mailing

If I buy virgin queens and have them mated in my yard, would they be just as strong and prolific as queens mated before they are put in the mail? How would you introduce them in a full hive during the honey-flow?

Mineola, N. Y.

A SUBSCRIBER.

[If you have them mated in your own yard they would be just as strong and prolific and perhaps more so, as if mated before having been sent through the mail. There is this one decided disadvantage—if they are mated in your own yard, they would necessarily mate with whatever drones might be present. In case you have black or hybrid bees your queens would be pretty sure to be mismated. The best plan for introducing virgin queens is the smoke method, which we send with each virgin queen sent out. Of course, in order to be sure of success the old queen should always be removed.—Ed.]

Wood Alcohol Dangerous

A. W. Smith, p. 291, April 1, advises the use of wood alcohol in imbedding wires in foundation. Would it not be well to warn the readers of GLEANINGS that wood alcohol is a dangerous poison? It sometimes causes blindness, and the fumes are very injurious to the eyes.

Boston, Mass.

O. H. HOWARD.

A. I. Root

OUR HOMES

Editor

Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me.—MATT. 25:40.

Give, and it shall be given unto you; good measure, pressed down, and shaken together, and running over, shall men give into your bosom. For with the same measure that ye mete withal, it shall be measured to you again.—LUKE 6:38.

I suppose the most of you, my good friends, have heard the story about a man who was moving with his family, household stuff, etc. While making the trip he was obliged to stop at a country hotel over night. This hotel was kept by a good Christian man. I wonder how many such there are nowadays who entertain travelers. Well, after things were taken care of for the night, the stranger sat down on the porch with the good landlord; and among other things he explained that he was going away off because of a mean neighborhood where he had been living, and he had such a mean lot of people around him that he had broken away and was going to get away from the whole gang, etc. The wise landlord replied something like this:

"My good friend, I am sorry to be obliged to tell you that you will find the same sort of people where you are going now."

I cannot remember exactly the rest of the story, but it ran something as follows:

Some time later, another family with a covered wagon, the owner's wife and children and all his household stuff, etc., *also* stopped with this same landlord over night; and, as before, in the evening they sat on the same porch and talked over matters. This second man said nothing would have induced him to move had it not been for the death of a dear relative, and he was really obliged to go and look after a considerable property. He said he hated to leave the people and the neighborhood where he had spent all his life, because there were so many exceedingly good and kind neighbors, etc. Now, what do you think this good landlord said? Why, he said as before, or a little, as you will notice, something as follows:

"My good friend, it gives me much pleasure to assure you that in your new home you will find very much the same kind of people as those you have left."

I suppose this old story has been considered as a sort of joke; but this time the joke really contains a blessed truth. It is something inside of us and not on the outside that makes a neighborhood good or bad. You who have followed me in these Home papers for the past forty years doubtless

remember many instances of where bad neighbors, or people whom some might consider bad, had turned out to be the best and kindest people in the world. It all depends, or at least largely so, on the way we treat people during this voyage we are all making from birth to death.

I am now going to tell you something that Mrs. Root would rule out if she could get hold of it before it comes out in print. Years ago I told you about our cabin in the woods, and the many attractive features in that wild place in the dense woods of North Michigan. After we had been there quite a spell, got our garden started, with flowers around the cabin, busy making the wilderness blossom like the rose, one day Mrs. Root said she was getting hungry for *woman* companionship. There were men and boys at work helping me grow my earload of potatoes; but she did not see any women-folks to gossip with, except at church and Sunday-school on Sunday. Then she began taking good long walks off by herself, calling on the different neighbors; and she used to tell me about the good and kind people she met here and there. They were a busy lot of people, especially during the spring-time and summer; but they were very kind and good people. Down in our Florida home it is much the same way. She went so far off getting acquainted with the "women-folks" that one day she got lost and had to inquire the way home. For several years past we have had one very near neighbor—so near, in fact, that Mrs. Root and her good friend Mrs. Harrison could call to each other from their respective porches; and how these women did visit and enjoy each other's society! It made me think of David and Jonathan. But after the dear friend of several winters past had lived to a pretty good old age, God called her way. Some new neighbors were coming to occupy the vacant home, and Mrs. Root was wondering what *sort* of people they would be. I made up my mind (before I knew *who* was coming), although I did not dare to say it to Mrs. Root, that she would discover, as she almost always did, that the new comers were "just the nicest people in the world," and my prediction came true. Let me give you an illustration:

Our windmill is an automatic oiler; and away up in the air, above every part of the machinery, is a reservoir that holds about a gallon of oil. This needs replenishing about once a year; and I have been in the habit of climbing up over forty feet and clinging

to the machinery as best I could when I filled the tank. It is not at all difficult for one who never gets dizzy, unless a gust of wind should swing the vane so one might get pinched in the machinery; but Huber and Ernest have remonstrated so much about my climbing up there at my age that I rather hesitated. One morning when the machinery needed oiling, my new neighbor was hoeing in his garden just over the fence. As he is a young man, and remarkably strong and spry, I asked him if he would help me a little in my work.

"Sure," was his reply, and he was over the fence and by my side in an instant. He filled the reservoir and then helped Wesley dig some potatoes that were to be delivered at a certain time. When I undertook to pay him for about half a day's work he stoutly declared, "Not a cent, Mr. Root. After you and your good wife have done so much for us, it was just a real pleasure to know that I could in some way help you out; and furthermore," he said, "if at any time when you are up in your northern home, you want either one of us to look after anything on your place here, just keep in mind that it will be a great pleasure for us to attend to any such commission."

How is that for neighbors? I can say with David, "I have been young, and now am old:" and, like David, I have observed, and this one thing impresses me, that it is almost always possible to bring out the good and noble qualities of your neighbors if you do not become "weary in well doing." Keep right on; do not mind the scoffs and rebuffs and unpleasant words. Watch for an opportunity to make friends. Send over some little thing from your garden, or some flowers, fruit, or a section of honey.

I have several times mentioned an exceedingly good and kind friend, Mr. Henry Borchers, of Laredo, Texas. Laredo is just on the line between this country and Mexico. From this friend I get many glimpses of the Mexican people and of what is going on there. You may recall that it was Mr. Borchers who sent me the feterita seed, and the feterita bread and cake. He sent me also about a dozen of the spineless cacti, and finally some of the cacti confection—enough of it so that I took some of it to the prayer-meeting, passed it around, and talked to the good people there about the spineless cacti, the papaya carissa, jaboticaba, etc. Well, I assumed that friend Borchers would at least let me pay the express charges or postage; but he sent my stamps back again, and here is what he said:

None, I don't mean for to pay anything about favors as I am only too glad to do you a good turn; for what you are doing is the Lord's work; and as

I am trying to serve him in every way I can, I feel that in helping you I am helping him. You are doing a wonderful work, and in any way that I can help you, *just command me*. I am at your service. I want you to let me know at any time if I can do anything for you down this way. I assure you it is a pleasure to me to assist you in any way.

You know I have had a great many kind words; but I believe the above, clipped from his letter, is not only about the kindest-word, but it pays me the highest compliment I have ever received; in fact, it is about the highest compliment any one *can* receive.

With the above good long preface I am going to submit one of friend Borchers's kind letters just received:

Mr. A. I. Root:—At last I am taking time to write to you and answer your questions as well as I can. I have been very busy, as the onion rush has been on in our section, and that turns money loose, and the people want bread. It makes business extra good for a while. It is also a very interesting sight to see the harvesting of the onions. There have been harvested so far about 2500 cars. Think of it—solid trains of onions leaving here daily!

You speak about Florida. I tell you, Mr. Root, Florida may have her crops, but Texas has hers also, and the onions I am writing you about are only from the Laredo section, Webb County.

Now, first I want to say about the alligator pear you wanted a few to taste. I am afraid that I can not get them for you, as one of the enclosed letters from the Department will show.

The larger avocado I may be able to get for you by special permission from the custom-house. They will be in the market across the river (Mexico) pretty soon now, as this is about the time for them, and trains are going to run again now to Monterey, beginning to-day; and just as soon as I can I will send you some—that is, if I can get permission to bring them across.

I am pleased to hear that you like the feterita seed, and will try it (boiling the whole grain) just as soon as I get some more.

I have taken some kodak pictures of the wild spineless cactus, with fruit only, as they have already finished blooming. They are not entirely spineless, but nearly so. Some have more spines than others. The people here use the fruit to eat, and also eat the young and tender slabs. They boil them in salt water about two or three hours until tender, and then cook them with eggs and a little onions, and some use a little red pepper. I have eaten them myself, and am very fond of them. The people here, mostly Mexican, use them during Lent, as that is the time the young leaves or slabs are plentiful. I believe you could also cook them like okra, and perhaps in other ways. You can also use the common cactus the same way; but it is quite a job to clean the spines off.

These wild spineless cactus, so far as I know, are only to be found in town here, and have been grown here for years. These pictures are all taken in back yards of the poorer population, and are not cultivated in this section for feeding stock—at least not that I know of; but the young slabs are sold in the market here the same as vegetables; and if they are still to be had I will send you a few.

The pictures (see page 549 and 550) of the common cactus were taken about seven miles south of Laredo near the Rio Grande. Some few were still in bloom, and I took a fairly good bunch of photos, all of which I enclose.

The picture of the young man on several is our minister (Presbyterian). This common cactus is

what we use for forage here, and you would be surprised to know how much of it is used. They build brush fires and singe the spines and feed it to stock. I buy it by the wagonload and feed it to my cows (I have three of them); and when I happen to run out, you don't know how much less milk we get. The stock will leave other feed to get the cactus. I am also sending you all the literature that I have received from the Department.

Have you ever found out anything about the beans I sent you (aba)? I wrote to the Department at the time I wrote about the avocado, but they entirely ignored my beans, of which I sent them a sample.

You ask me if I have bees and a garden. Yes, I have a garden in my back lot, but no bees. I take GLEANINGS only for the Home department, gardening, and the temperance section by A. I. Root. That ought to make you feel good. You are sowing the seed more than you think. Just let me tell you about something you did the other day. You gave my address to a certain seed-house, and I sold them over twenty dollars' worth of seed that I happened to have on hand (guada bean), and they made me an offer which I accepted; and when I received the money I sent it to the Anti-saloon League of Texas to help make Texas dry. Keep up the good work, and you will be surprised when harvest time comes.

About guada beans, that reminds me that I sent to my baker's supply house for some angelique for use in a recipe (cake); and what do you think? I received some guada beans done up like glazed fruit. There can be no doubt about it. I have it here, and will send you a piece of it. I am also going to send you some more cactus confection.

If there is any other way that I can serve you, let me know, and I shall be glad to do so.

If you ever come to Texas I want you and Mrs. Root to visit us. I began this letter yesterday, and just came back from town. I could not get any real nice cactus confection; but as soon as some fresh arrives from Mexico I will send you some. I am enclosing all literature and correspondence that I have from the Department, and want you to go over it carefully, especially that in regard to the tuna confection. I wish I could have been at your prayer-meeting and heard your talk.

Laredo, Tex., May 25. HENRY BORCHERS.

From the above it transpires that not only the fruit but the cactus slabs, when they are small, can be used for food. In regard to cactus plants for cows and other domestic animals, see article in last issue.

The aba bean mentioned above makes a most astonishing growth on our Florida soil. The beans are about as large as or larger than our largest lima beans. They are red in color, and grow on bushes two or three feet high.

"GETTING EVEN;" A COMPANION CLIPPING TO
"THE DEFEAT OF INJUSTICE."

The following was also clipped from the *Sunday School Times* of a recent date:

GETTING EVEN

To get even with one who has wronged us is to set down as low as he is. The more outrageous his injustice, the lower we shall have to go if we insist upon getting even with him. So "getting even" always leaves us worse off than we were before. If ever one man was unfairly treated by another, it was David, at the hands of Achish, afterwards, by infuriated Saul. But when David's chance to get even

came, he preferred to stay on the heights. To "revenge" ourselves is to return the sort of thing that was given to us. It is as though, having been cheated by counterfeit money, we wait for an opportunity to pass some of the counterfeit back to the cheat. No matter what we have suffered, we cannot afford to do that; for then we have been injured twice; and the second injury is far worse than the first. There is a better way of getting even with one who, in order to harm us, has descended to a low level. It is to stay above him in God's company, and by love to bring him up to that level.

Before considering the above, permit me to say that we have now printed and given away something over 20,000 copies of the little tract, "The Defeat of Injustice; or, How to be Happy when People Abuse You." When I saw the editorial in the *Sunday School Times* about "getting even" it impressed me that it should be added to our little tract. By the way, one of my greatest temptations all through life, even since I became a Christian, is to "pay back in the same coin." Somebody has wronged me, or at least it seemed to me that way, and, rather than have a fuss or a jangle, I have "swallowed it down" and looked pleasant, and decided to let it drop like "spilled milk." But there is almost always a temptation to say to myself, "Some time when the chance comes" (and it almost always does come) "I will remember this." But a better spirit (and one that rejoices my heart to remember) almost always, or at least a little later, crowds out the ugly and unchristianlike attitude of mind; and this better spirit, the still small voice, says, "Forget that it ever happened, and treat this poor brother as if it had never happened." And this sort of treatment is what clearly defines and marks the true follower of the Lord Jesus Christ. The great outside world sees it, and at once recognizes the genuine coin. Dear brother or sister, whoever you are, and wherever you are, is not this the best way to get along in this world? And when you come to die, will it not brighten your last moments by remembering that you tried honestly and earnestly to "love your enemies and do good to them that hate you"?

STILL PREACHING AT THE AGE OF 112.

Our long-time friend Burdett Hassett, now of Alamogordo, N. M., sent us the clipping below:

TWELVE YEARS PAST CENTURY.

The Topeka *Capital* says that the Rev. M. A. Cox, 112 years old, is pastor of the Methodist Church at Alma, Kansas. He has been preaching for forty years. Before this work, he was a farmer. He hitches up his team and drives to church every Sunday, arriving in time to receive his congregation at the door. He is a native of Long Island, New York. His wife died when she was 101. He has been the father of eleven children, eight of whom survive. He has forty-five grandchildren and twenty-nine

great-grandchildren, and a raft of great-great-grandchildren. One of his grandchildren, living in Topeka, is the mother of nine children.

Attention is being called to the fact that, although the United States, and perhaps, for that matter, the whole wide world, is giving just now great attention to producing better domestic animals, nothing is being done, or comparatively nothing, in all

the world, toward peopling the world with better men and women. The above seems to be a start in the right direction. If it is indeed true that this good man has been a hard-working farmer and a hard-working minister throughout all his long life, I venture to say that that great crowd of descendants are, at least for the most part, a blessing to the world.

HIGH-PRESSURE GARDENING

SWEET CLOVER: POSSIBLY A NEW VARIETY.

A little north of Medina, near our basswood orchard (on the premises of a cousin), while looking over a field of red clover I found here and there some stalks of sweet clover. This is not at all strange, as sweet clover is growing with great luxuriance all along the roadside ever since the road was paved with crushed limestone. This matter has been referred to before—namely, that lime or limestone is needed for all the clovers, especially sweet clover. Well, all at once my eye caught sight of a plant twice as high as any of the rest, with leaves three or four times as large as the other sweet clovers, besides being slightly different in shape of leaf and manner of growth. At first I thought it was not sweet clover at all; but on closer examination, and by crushing the leaves so as to get the peculiar sweet-clover smell, etc., I decided it was either a sport or due to some accidental extra fertility in the soil. I questioned my cousin, and asked him if it was possible that a dead animal had ever been buried there; but he thought not. About a rod away I found another but smaller plant having the same peculiar leaf and foliage. I cut off a couple of branches and sent them to our experiment station, and with it a letter explaining the circumstances. Below is Professor Thorne's reply:

Mr. A. I. Root:—I have yours of the 7th, and am much interested in your observations respecting sweet clover. I have referred your letter to Mr. Williams, who is looking after such matters, and he has no doubt that the plant you have found is a mutation, and that it would be well worthy of propagation. If you succeed in growing seeds from it, we shall be glad to receive a few seeds for further experiment. We think it more likely to be a mutation which may have permanent value than to be merely due to superior soil conditions around that particular plant. Of course, this cannot be determined without further experiment.

CHAS. E. THORNE,

Director Ohio Agricultural Experiment Station.
Wooster, Ohio, June 9.

I have just been down with a good sharp spade and hoe and cleared away the other weeds and clover for the distance of a yard

or more all around the plant. I am going to give it careful cultivation, some lime, and possibly some stable manure; and just as soon as I can get seed ripe enough to grow I will plant it and try, if possible, to get plants that will winter over. The question is, Will these new plants duplicate the parent? If so, we shall have a new sweet clover. See pictures on pages 536 and 537.

Judging from the habits and appearance of this one plant it would furnish double the amount of feed, may be three or four times as much, as the old sweet clover. I may remark that we have just cut and cured two or three acres of yellow sweet clover, and we are planning to get a crop of seed. But we have been told the seeds will ripen even if one cutting of hay is taken off during May. In our locality sweet clover furnishes green feed quicker than any other plant we have ever experimented with. If you will not accuse me of "counting my chickens before they hatch," I will say I am planning to give just a few seeds to any of our readers who may be interested in this promising new God-given plant to the children he loves and to the children *who love him*.

FETERITA—MORE ABOUT IT.

We clip the following from *Field's Seed Sense* for May, sent out by the Henry Field Seed Co., Shenandoah, Iowa. Although the clipping below comes, as I suppose, from an advertising catalog, it contains valuable instruction in regard to growing this new cereal; and, so far as my experience goes, it is just about right.

FETERITA THE IDEAL CHICKEN FEED.

Incubator Johnson certainly started something when he mentioned in his circular that now would be a good time to plant feterita for chicken feed and save the high-priced wheat.

You know I have been growing and selling feterita for two or three years, and am very enthusiastic about it, and knew that it was splendid chicken feed, but I never thought to mention it. I guess I just took it for granted that everybody else knew it too, and, furthermore, I never got it through my head how hard it was going to be for the women folks to

get wheat to feed their chickens now that wheat is selling at \$1.50 per bushel. I might have known, too, if I had stopped to think. Any way, Incubator Johnson, who is mighty good authority on chickens and their troubles and needs, mentioned in his circular that every one ought to plant a little patch of feterita for chicken feed and save the high-priced wheat, and I guess we have had 1000 letters about it in the last six weeks.

As usual, Incubator Johnson is absolutely right. Feterita is just made on purpose to feed chickens. It is the ideal chicken feed in every way. It is a better-balanced ration than corn or wheat. Chickens will eat it greedily, and will thrive on it. It cannot hurt the chickens in any way. It is just the right size for them to eat; and if you want to you can throw it to them in the head and make them scratch it out. It will keep all winter like wheat or corn.

The best thing about it is that anybody can grow it in any part of the United States. I don't suppose there is a state in the Union where you cannot grow feterita. It is as early as the very earliest hardiest field corn. It will mature easily in from 75 to 90 days of summer weather. It will yield more than field corn; even under unfavorable conditions it will make a good crop where field corn would make an absolute failure.

It will stand more drouth than any other crop I ever saw. Down in Oklahoma, in the dry weather they made a good crop with it with only five inches of rain for the entire summer, and only one inch of rain between planting and heading.

It should be planted in rows like field corn—just about the same distance in the rows—that is, one seed to every five or six inches in the row. This may look thin, but it is the best way to plant it. If you sow it thick it will make very little grain and lots of fodder; but if you get about one good stalk every six inches in the row, and the rows three to four feet apart, every plant will make one big head and three or four small ones, and a big head of it means about a pound of grain.

It should be planted later than field corn. This would mean anywhere from the middle of May to the first of June according to your climate. If you are in the habit of planting field corn about the middle of May, then wait until about the first of June to plant the feterita, or until the ground and weather are thoroughly warm. Don't plant it too deep. It should be planted shallow—never more than an inch deep.

It should be cultivated just like field corn or sweet corn, or any other similar crop. It can be hoed or tilled with a horse.

It heads very rapidly, and is ready to harvest in August or September. The best way to do is to go through with a knife and cut the heads off and carry them out just as you would ears of corn. Pile them up in a corn-crib or granary, or some such place, where they will be dry, and they will keep just like ear corn. The fodder is as good as corn fodder, and can be cut and shocked the same way. It makes splendid cow feed. You will need about five pounds of seed per acre, although some people get along with as little as three pounds. It depends on how careful you are in planting it.

It is somewhat similar to kaffir corn, but is better on account of its earliness, heavy yield, and its extreme drouth resistance. It will stand more drouth than kaffir corn, will make a heavier yield, and on account of its earliness can be grown much further north or northwest. It is better than shallu or Egyptian wheat for the same reason. It is earlier and heavier yielding than milo maize, and is much better than field corn, because it will stand much more drouth and will do better in small patches. It will grow on any soil, no matter how thin, but will make the best yield on fairly rich soil.

Here is what a customer in Oklahoma has to say about feterita:

"Well, Mr. Field, I guess I know just about as much as any farmer about feterita. It is the best all-around crop ever planted in Oklahoma. I have raised three crops of it. It will average about 50 bushels to the acre, one year after another, but I think 100 bushels or more can be grown on one acre under favorable conditions. The main thing is to plant it very shallow; $\frac{1}{2}$ inch is plenty deep. It is the best crop a lazy man ever planted. It will yield more without rain or cultivation than any other crop you can plant."

CASSAVA, DASHEENS, AND PAPAYA.

On page 471, June 1, our good friend Thompson wonders if their manioea is identical with our cassava; and at the time he wrote that letter he very kindly sent me a package of cuttings of their manioea. They were at once turned over to my good neighbor Harrison, who lives close by our Florida home. Here is what he says about them:

Mr. A. I. Root:—The feterita is as tall as I can reach. Nearly all has headed. Another papaya is turning yellow. The canes that came from Africa have begun to grow. Five leaflets are in sight, and one is three inches tall. I will see to transplanting when they are ready and we have a good shower. We are enjoying the abundance of little yellow pear tomatoes. C. L. HARRISON.

Bradentown, Fla., May 26.

In regard to the pear-shaped tomatoes mentioned above, permit me to say that the finest tomatoes we grew last summer here in Ohio—in fact, it seems to me the finest tomatoes I ever tasted—were some yellow pear-shaped tomatoes. The vines ran all over the garden like cucumber-vines; and under the stimulus of plenty of manure they produced tomatoes almost as large as small hen's eggs. They just made the ground yellow. I took some seeds down to Florida, but they did not grow as large nor as fine as they do here in Ohio.

Below is a letter from a good brother in regard to the papaya fruit in Cuba, etc..

Mr. Root:—I have read for some time with interest all you have written about your Florida farming. In the April 1st and May 15th numbers you mention the papaya, which, being so common here, I wonder if we could not give you some ways to use this exceptionally fine fruit that you have not tried; at any rate, there will be no harm done in telling what we do with it.

Of course, when ripe you know how fine it is, eaten like any northern cantaloupe, with salt or sugar according to the taste. Before it is ripe, and while still quite green, or, rather, all green in color, peel and slice the meat and prepare as you would an apple for sauce, adding some lemon or lime juice or other fruit juices if you prefer; but with the lemon the sauce thus prepared can hardly be told from the real apple article, and in pies is very fine, or, made into shortcake, equally good. When well ripe, if peeled and the meat run through a colander, then handled same as pumpkin, it is hard to tell the difference. We have had many tourists come here who would discover a pumpkin in their rambles, and, of course, want a pie; and after they had carried the pumpkin to the house we would substitute the papaya without their detecting the substitution.

Our trees must grow larger than yours. I have seen them here 25 or 30 feet high, and a foot through at the bottom. This morning in riding

across the country some 25 miles from my place I saw a tree in a Cuban's yard that had over 50 fruit on it. Three years ago I had a friend who planted many of the papaya-trees in order to sell the fruit. He had a seedless variety, and they were very large and much nicer-flavored than the ordinary, I thought. I don't know where they came from, as I had never seen any like them before or since, but could no doubt find out very easily, as he is still in Cuba. I have the papaya-trees planted this year 8 feet apart in front of 300 colonies of bees at this place. I believe they will give me ample shade, and at the same time not interfere with working around them. In Mexico they sear the skin when green, and a white milk collects and crystallizes, and this is sold, I believe, to Park Davis & Co., for making some kind of stomach medicine. The dry crystals, I believe, are worth about \$40 per lb. This is what I was told, but cannot vouch for the truth of it. The chickens and pigs seem to like the papaya very much; but what value as a food for such animals it has I do not know. The male trees do not bear fruit here.

We hear much about the dasheens of Florida, and from the pictures and descriptions have often heard it said they were the same as our malanga. There are two varieties, but one is not edible. The potatoes are the only part ever eaten here to my knowledge, and then but seldom, although the malanga grows in most yards among the Cubans. Perhaps when you again go to Florida I might send you some things we have here wild that are new there, and would be very glad to do so if you would be interested.

Holguin, Cuba, May 23.

D. W. MILLAR.

Many thanks, friend Millar, for the information you give us. I knew that a medicine was prepared from the papaya fruit, but I did not know before how they managed it. I am pretty well satisfied that the fruit when dead ripe is a help to good digestion. There are trees in Florida very much larger than my own; but as they are sensitive to frost, unless when near water, they are often cut back. In regard to the male trees not bearing, a missionary in South America who visited our garden told me they did *sometimes* bear, but that the fruit from such trees was on the end of a long string or cord; and we had about half a dozen such fruit on one of our trees. The fruit does not look like the one pictured from the female tree. I also saw the malanga during the winter I spent in Cuba; but the quality of the tubers was very much inferior to our Trinidad dasheens.

My good friend, I am exceedingly obliged to you for your kind offer; and if you *can* send me a little plant of the seedless papaya, or one that is nearly seedless, I would pay almost any price for it.

HEALTH NOTES

"FLUID ENSEROL" AND THE VALUE OF BORACIC ACID FOR THE EYES, EARS, ETC.

On page 742, Sept. 15, 1914, I gave my experience with the so-called fluid enserol. Below is a letter in regard to the same matter:

Mr. Root:—A good many years ago my father worked in the boiler-works and lost his hearing, and was not able to hear unless a person was quite close and raised his voice very high. About a year ago last fall he received this booklet, "A Woman's Story," and sent and got the prescription filled, and started to use it early in the fall, and continued to use it all winter. Along in the spring we were sitting on the porch waiting for supper when mother spoke from the kitchen and said, "Supper is ready." He turned to me and repeated it; and as she was across two rooms from us, and spoke in an ordinary tone, and I had barely heard her, I asked him if he had heard her say so, and he said he had; and then he took out his watch and could hear it tick in one ear. That was the first time he had heard a watch tick for 25 years, and he was much pleased over it, I tell you. But it did not last long—only a few days, and then he was worse than he had been before. But he had faith in the medicine and kept on using it; and after a couple of weeks his hearing came again, and he could hear so well that it hurt him; for if he was near the railroad he had to hold his hands over his ears; and while driving along the road, and the wagon would rattle, he would get off to see if something was wrong, as it was so loud to him. Soon his right ear quit again; but he can still hear well out of his left, and can hear an ordinary conversation in a room or outdoors ever since; but his right ear is still deaf. He still uses the

medicine, but it is so old he is going to get some new, and feels that it will fix that one ear up too.

There are hundreds of people who can verify all this, and a good many are using this medicine after seeing what it did for him, and some have been benefited already, while others are still using it. Now, if Mr. Root is hard of hearing, or any other person, I would advise such to use this and not despair, as I feel sure it will fix them if they keep right on long enough.

It was fully six months before it helped father; but it stopped the noises in his head in a few weeks, and he says that was worth all the money invested, because the noises were awful all the time. He compares them now to a big storm coming up roaring through the woods, and he never heard these storms until after he got to hearing things.

Springboro, Pa., March 9. FRANK P. DORE.

I am exceedingly glad to get the above, for it verifies what I suspected before, that boracic acid, very much diluted, of course, is an excellent remedy for eyes and ears. In fact, I believe this is well known and well recognized by medical men for years past. Our friend who writes the above speaks of noises in his father's ears, which he endured while the deafness lasted. This reminds me of something I had forgotten to mention. There are times when I hear a roaring, something like the cars coming or a storm far away. Here in Medina I have often asked Mrs. Root if she heard a roaring. Of course she did not. The use of

boracic acid in the ears of the patient cleanses them more effectually than soap and water or anything else I have ever tried. Some time ago I told you about using it for an inflamed eye; and I see it is frequently mentioned in medical journals or in articles on medicine. Now, here is a point, however, that must not be lost sight of. I paid \$1.25 for an ounce of this fluid enserol that did not cost more than a few cents. To keep the matter before us I have been examining druggist's wholesale price lists, and I see fluid enserol quoted at 85 cts. an ounce.

It indicates that a big lot of the much-advertised patent medicines are only common well-known remedies with some fictitious name tacked on to them. In the magazine called *The Good Health Clinic*, for May, a list of about twenty advertised medicines are given, and I think the list was taken from *Harper's Weekly*. Here is one of them:

Murine—once a "cure," but now a "remedy" for sore eyes; a plain boracic-acid wash. Sells for \$1 an ounce, and can be made for about five cents a gallon.

You will notice this "Murine" is the same old boracic acid under a different name—the dollar-an-ounce medicine that can be made for five cents a gallon. Here is what the editor of the magazine says in regard to it:

These well illustrate the "Two Biggest Frauds on Earth"—the fraud that takes \$1.00 of a man's money for what costs one cent and the fraud that gives him the expectation of the relief and cure of his diseases by way of some drug poison—and the common name of both these frauds is "Medicine."

E. E. K.

While we are about it, I wish to make just one more clipping from this list of

medicines or foods. It is in regard to our old friend sanotogen:

Sanotogen, "the life food and nerve tonic"—just plain ordinary cottage cheese prepared in powder form.

Here it is again, a dollar a bottle for cottage cheese which is sold in our Medina markets for 10 cts. per lb., and at the same price away down in our Florida home, and probably all over the land. It is, as is well known, a very wholesome and concentrated article of human food. No doubt it helps many people who have not been accustomed to use or get acquainted with cottage cheese, and may be it will do more good because it costs a dollar a bottle than if they got it for 10 cts. per lb.

In closing, just a word to our friend who has trouble about hearing. Go to your druggist and get the remedy, and use it as described in the journal referred to, for last year. But instead of paying \$1.25 an ounce for enserol, go to your druggist and get some boracic acid. He will tell you about the quantity of it to use to make it good both for eyes and ears.

And there is something else you should keep in mind: It is not positively *sure*, although it is quite probable, that this man's hearing was restored by the enserol. If you look about you, you will find that old people frequently get back their sight—yes, and in some cases hearing also—without taking any medicine whatever. A few days ago I was surprised and delighted to note that I could read an ordinary newspaper while standing outdoors, without my eye-glasses. Now, had I been taking some sort of "treatment" in order to see without the aid of glasses I might have been ready to swing my hat and give a big testimonial.

TEMPERANCE

GOD'S KINGDOM COMING.

I am surprised at you, brother Root. If you were a young man, and had no personal knowledge of how the Devil has been licked over and over for the past seventy years or so I could account for your pessimism. I am only 42; but I have seen so many unexpected public reforms occur in my lifetime that I think amazingly rapid progress has been made. Perhaps your article in your June 1st issue means you become discouraged only over the liquor-traffic. You say, "We get answers to our prayers in everything except in regard to the liquor traffic." Now, do you not think you really ought to ask the Lord's forgiveness for such an incorrect statement when you stop to think of how even the preachers drank, and an active prohibitionist was about as welcome in a church as skunk in a beehive? At least that is what the historians tell us; and even within my own memory drinking church-members have left my own denomination, the Meth-

odist, for some more liberal on the liquor question. But to-day they find that all the denominations denounce them; and when we look at the diagram maps the Anti-saloon League issues from year to year, and see how the black spaces have been so marvelously reduced (indeed, they have to print new maps oftener than once a year to keep up with the progress), I feel like shouting "Hallelujah!" that I should live to see this. Think of the early temperance reformers. My grandfather was a Washingtonian. I suppose they get the election returns in heaven; and if they rejoice so much over one sinner that repenteth, they must be singing a mighty chorus as, month after month, the reports come in of whole states and even whole nations driving out the liquor saloons.

If, even in the darkest hour, God is able never to leave himself without witnesses, and has at least seven thousand who refuse to bow the knee to Baal, why should any one become discouraged when we

lift up our eyes and see the fields white for the harvest with more than seventy times seven thousand added to prohibition territory every few months? What must those women who started praying in saloons with their crusade so many years ago think as they see the changed conditions of to-day?

We are living, we are dwelling,
In a grand and awful time,
In an age on ages telling—
To be living is sublime!

In the very same mail with GLEANINGS comes the June 4th issue of the *New Republic*, and I see the big Brunswick Balk-Collender Co., the largest manufacturers of bar-fixtures in the United States, has quit the business, and sent its formal notice that "We will discontinue the line absolutely." Why, your statement about the Lord not answering prayer for victory over the saloon sounds to me almost blasphemous after reading a newspaper item like this. But that is not all. On the next page is another item saying that in Ohio under the glorious privilege of the initiative and referendum it is so blessed as to enjoy, the Anti-saloon League has more than 200,000 signers on its petition for statewide prohibition; and the question will be voted on next November. Praise the Lord for Ohio's initiative and referendum! I most earnestly pray that the enemies of God who have so long held Indiana in political slavery without the rights of freemen that exist in the other states of our country, shall by some means be overcome, and that we too can get the initiative and referendum. When we do, then we too can submit the question of statewide prohibition. Until we get the initiative and referendum our case is hopeless. We asked the legislature last winter to submit the prohibition question, but as usual the request was refused. Of course the people's vote must be campaigned, for even under the initiative and referendum the people may vote down prohibition; but the initiative and referendum gives the chance to make a campaign for prohibition, and we can get that chance no other way. GLEANINGS ought to boost the initiative and referendum at every opportunity because it helps prohibition.

Greencastle, Ind., June 4. DANE S. DUNLOP.

My good friend, I own up and stand rebuked; but at the same time I wish to explain that when I referred to prayers unanswered I had in mind the matter of license and revenue, which Lincoln consented to under protest. While the people of the United States knew exactly what he said and what he meant, this "shame and disgrace" to the American people has been permitted to go on year after year for *forty years*, notwithstanding our prayers and protests. Our innocent wives and children have suffered and starved for forty years just because the common people, such as you and I, were afraid to stand up and demand that this Achan, with his wedge of gold, should be cast down and out. Yes, we have abundant reason for thanksgiving, for "God's kingdom is coming," even if it has taken us long years to wake up and *work* as well as pray.

While we are considering this matter, I notice that Dr. Miller says in *Stray Straws* for June 15, "I plead not guilty." That is true, doctor, and we rejoice over it; but, notwithstanding, it is true that *we Ameri-*

cans have *permitted* this thing to go on for over forty years.

IOWA'S EMANCIPATION, ETC.

The Iowa legislature has just passed a law repealing the "mulch law," also a resolution submitting an amendment to the constitution of the state, allowing equal suffrage. As most people know, Iowa had statutory prohibition; but owing to non-enforcement thereof it was unsatisfactory, and what is called the "mulch law" was passed some twenty or more years ago. This "mulch law" provided that certain communities, generally counties, could, by circulating what became known as "saloon consent" petitions, disregard the prohibition law, provided a certain per cent of the voters signed it. The number of saloons was limited to one for so many of population, and the license was, I think, left to be fixed by the city authorities where the saloon should be allowed.

In communities where the foreign-born population held the balance of power, as they do in some parts of the state, the "mulch law" was an improvement in practical results over prohibition, for in such communities prohibition was a dead letter, and booze was free and uncontrolled. But the saloons near the edge of the "wet" territory were always a curse to the adjoining "dry" territory, because it is so easy for those so disposed to go by team, by auto especially, and by train, and, after filling up themselves, bring back some in jugs and bottles. "Stolen waters are sweet," so that liquor, thus obtained, no doubt tasted better to some than if they could step into a saloon any time at home and get a drink.

Billy Sunday held meetings in Des Moines last fall. After that, if I mistake not, an "anti-saloon" petition went around, and Des Moines went "dry;" then the dries got busy in the legislature, with the result as stated. There is a strong prospect this time of the legislature making extra provision to enforce prohibition by state marshals appointed so as to be independent of local sentiment. There is a statewide demand for enforcement, which is what prohibition has always needed, and lacked in so many instances.

It is commonly expected that equal suffrage will carry. Prohibition goes into effect Jan. 1, 1916.

Dunlap, Iowa, March 9.

E. S. MILES.

GOD'S KINGDOM COMING.

From the *Cleveland Plain Dealer* I clip the following heading:

DRYS WIN OUT IN EAST CLEVELAND, CAST 1543
VOTES FOR PROHIBITION UNDER BEAL LAW;
212 AGAINST.

I submitted the above to Ernest, and asked him what it meant that a part of the great city of Cleveland should give such an astounding majority for prohibition. He said one reason for it was that *East Cleveland* is made up mostly of resident districts, and that, no doubt, even the saloon-keepers and brewers *themselves* do not want saloons in the vicinity of their homes.

THREE CHEERS FOR ALABAMA; GOD'S KINGDOM COMING.

The Alabama Supreme Court has declared constitutional the law forbidding papers or magazines to print advertisements of liquor. This is important, because it deals with the right of the public to determine what a paper shall print. The point was that, so long as the liquor interests could advertise largely, they could control the policy of the newspapers.—*Rural New-Yorker*.

EDITORIALS

A New-old Method of Swarm Control that Promises Much

IN this issue, on page 573, the reader's attention is directed to an article by Chalon Fowls. If the reader can wade through our long introductory he will see there are certain references in connection that will be worth his while to go over carefully, especially if swarming in season and out of season is one of his troubles.

Our columns are open to a full discussion of the subject, and we hope many questions will be asked.

Chocolate Honey Candies

MR. EDWARD HASSINGER, on page 531 of our last issue, speaks hopefully of making honey confections by coating granulated comb honey, and ordinary comb honey not granulated, with chocolate. Apparently he has not made a success of the idea. We may say for his information that quite a number of beekeepers have done it, including the A. I. Root Co. We have sold granulated extracted honey and little chunks of comb honey covered with chocolate. There is no trouble about doing this if one understands the art of making candy or handling chocolate. These honey chocolates are very fine. The only objection is, they are *too* good. They are so concentrated a sweet that one can eat but a very small amount.

Politics and Wire Pulling in Pennsylvania

IT will be remembered that there was some prospect that the State of Pennsylvania might appropriate \$50,000 for bee-inspection work and to carry on apicultural investigations. This was finally whittled down to one-tenth the amount, or \$5000, and at the last moment this has been cut in two, or \$2500. This, however, will be a good deal better than last year, and we suppose the beekeepers of the state will have to be thankful for what they got; but at the same time it is not enough to cover

the state. If the governor wishes to promote agriculture he must commence with the most neglected branches, and he must see that enough money is given them to insure their proper development.

The Apicultural School at St. Paul, Minnesota

THE apicultural school that has been doing such good work under Prof. Francis Jager, at St. Paul, Minn. (see page 541, last issue), is to have another man to help in the person of Mr. L. D. France, of the University of Wisconsin, in the capacity of assistant professor of bee culture. The Franceses are all expert beekeepers; and the young Mr. France, son of N. E. France, many years General Manager of the National Beekeepers' Association, and foul brood inspector of Wisconsin, will be well equipped for taking up the practical as well as the scientific end of the business.

Newspaper Men Eat Honey

AN "All-Oklahoma Dinner" in which Oklahoma honey figured prominently was that given the State Press Association by the A. and M. College at Stillwater last month. Rev. R. S. Satterfield, Pauls Valley, owns the apiary which produced the honey. Mr. Satterfield is vice-president of the State Beekeepers' Association.

The banquet meats, flour, salt, grape juice, ice cream, peanuts, and even the waitresses, were all Oklahoma products gathered within the state boundaries by the committee from the college faculty in charge of the dinner arrangement.

It was, of course, impossible to ignore the position of the honey as a prominent Oklahoma product.

Here is more Sweet-clover Publicity

"SWEET CLOVERS. Some Facts of Interest about this All-around Forage Crop and Soil Renewer," is the title of a 30-page illustrated booklet just off the press.

A member of the GLEANINGS editorial staff has simmered down the information in the national and Ohio bulletins on sweet clover and in the pamphlet, "The Truth About Sweet Clover," written by A. I. Root. The writer has added some new information which has been brought out of late in farm magazines and in GLEANINGS.

The wide adaptability of sweet clover, its value as a soil-renewer, its usefulness as pasture and hay, and the methods of securing a good stand, have been featured in a logical and readable manner.

To individuals making application we shall be glad to send these booklets for one cent to cover postage. Organizations can secure them in reasonable quantities free of charge by giving the name of the president and secretary and stating the number desired.

Fire Damage of \$15,000 to R. G. Coombs

It will be remembered that some time ago a brother-in-law of Earl M. Nichols, Mr. Herbert F. Cary, of Lyonsville, Mass., a dealer in beekeepers' supplies, was killed in an automobile accident—p. 878, 1914. The death of this brother-in-law handling another line of their business made it necessary for Mr. Nichols, his partner, to give up the bee supplies, and he sold out to Mr. Robert G. Coombs, of Guilford, Vt. Since then, Mr. Coombs, on June 22, suffered the loss by fire of his factory building, containing some \$15,000 worth of bee supplies. In the mean time, he himself was taken down with appendicitis. Fortunately the fire did not cause a total loss, as some of the goods were stored in a private dwelling. Nothing has been said as to whether the property was covered by insurance. In the absence of any statement to the contrary we assume that it was, and that the business will be taken care of as formerly as soon as Mr. Coombs recovers. Further particulars will be given later.

How Advertising Confidence is Created

FROM breeders of bees and queens who seek to use the advertising pages of GLEANINGS we have been expecting certain explicit information regarding their plans and ability to back up their promises with performances.

We have been requiring to know of every one taking space in our columns how large his yard, the quality of his stock, when he expects to make his deliveries, and especially have we required reliable information regarding the character of the advertiser

and his ability to refund promptly money which has been placed in his hands for certain orders.

The difficulties of the queen business in this country are almost as great as those of the king business in Europe.

For the protection of subscribers, therefore, it is only fair that we scrutinize the promises so closely. Since this reacts favorably on the value of the advertising itself we are not surprised to receive numerous letters in the vein of the following from a well-known firm of queen-breeders:

Permit us to express our most sincere esteem of your firm. The stand you are taking in refusing advertisements in GLEANINGS has increased our estimation of that periodical more than we can tell you.

Advertisers recognize that the appearance of their announcement in GLEANINGS IN BEE CULTURE is itself a credit rating. Buyers understand this, and are ordering in confidence.

Moving Bees in Carlots from North to South Not a Financial Success for Honey Alone

ELSEWHERE in this issue, page 587, will be found a report by E. R. Root, of moving bees from north to south. It is much easier for one to tell about his successes rather than his failures. Perhaps in this case we should refer to what has not been a great success. While we have not lost anything in moving bees from south to north we cannot say that we have made very much money at it. The railroad companies charge so high a rate on bees, plus the railroad fare of the attendant, that they will shut out migratory beekeeping on a large scale. It cost us nearly \$2 a colony to move a carload of bees from the North to the extreme South, and of course it costs as much to get them back. It goes without saying, that no man who is working for honey alone can afford to take the chance. Even if he can get three dollars' worth of honey in the South, and three dollars' worth again in the North, after the bees are moved back, he would hardly get enough to pay for his own time, for the simple reason that he would have to pay out two-thirds of his gross proceeds for transportation alone. But it is quite a different proposition when one moves bees south for making increase, and then sells the bees at a fair price on arrival back north. If he can secure a crop of honey while in the South, he is so much ahead. From the first two cars we did this; from the two cars last year we didn't; but from the two cars this year we may do it again.

Clover Prospects and Honey Crop

It has been a most peculiar season so far. A comparison of the weather maps seems to show that conditions at Medina have not been materially different from other clover localities in the northern and central states.

We would have one or two days of bright sunshine and warm weather, during which the bees would rush out on the clovers—alsike, white, and sweet. Later on came the basswoods that yield heavily in the morning; and just as the bees would get to the point where they would begin to fill their combs, rain or cold weather followed. This program of two days of good weather followed by two days of cloudy, cold, or wet has been re-enacted back and forth for nearly six weeks. Fortunately the copious rains every three or four days have delayed the cutting of the alsike in the fields, and given a new growth to white clover and sweet clover. Notwithstanding white and alsike have been in bloom for five weeks, there are at least two weeks in sight of abundant bloom at this date, July 9. Basswoods are out in all their glory. They never yielded a heavier bloom if we could only get the weather. Notwithstanding these diverse conditions our hives are filling up with honey, and stronger colonies are storing a little surplus.

If Medina and vicinity are any criterion there will be some clover honey, both comb and extracted. If we could have two weeks of favorable weather, 1915 might go down as a real old-fashioned clover year. At present writing no one can make an accurate forecast. But it is safe to say there will be some clover and of a fine quality. Whether the general aggregate crop over the country will be light, medium, or heavy, is yet to be determined. It will be medium in some localities and light in others. In some few favored spots there will be a heavy yield of basswood, and clover, for this appears to be a basswood year.

Conditions have not been entirely favorable for alfalfa honey in the Rocky Mountain regions; but as those localities always furnish some honey, it is probable there will be from a light to a fair yield of alfalfa, both comb and extracted. The cheaper grades of honey, including the ambers, will not be as much in evidence this year as last. Indeed, the crop will be light. We are assured now of at least a light crop of sage in parts of California and of alfalfa in the Rocky Mountain districts, and a light crop of clover in some of the clover districts of the North.

Prices ought to be reasonably firm. There will probably be no great glut of honey of any kind, this year. What there will be, will be confined to table quality that ought to find a fair market. Those who were wise enough to run to comb honey will have no trouble in disposing of it at fair prices provided it is No. 1 to fancy; but those who continued to produce only extracted will have to watch their chances to get best prices. These are usually secured early in the season.

Later, July 13.—Since writing the foregoing, conditions for honey production have improved very materially. The weather has turned hot and remained hot. Honey is now coming in at a rapid rate—very much better than it has been doing before.

Reports from over the country so far show that one-third indicates a good crop; one-third, from one-half to a fair crop; and one-third show a short crop or none. Early reports were less favorable than those that came in within the last few days. It would not be surprising if there would be a good yield of clover and a little basswood throughout the north-central states. There is at least two weeks of clover in sight.

The Most Eminent Pennsylvanian

THE editors of papers and periodicals in Pennsylvania have been asked by Governor Brumbaugh to name the most eminent Pennsylvanian. As GLEANINGS IN BEE CULTURE reaches several thousand readers in the Keystone State we feel that we at least have a right to interpret the Governor's invitation as applying to our knowledge of the men in that state.

Persons engaged in any business become accustomed to thinking in the terms of their business; and those who are devoting their attention to certain lines of activity or specialty become better acquainted among themselves and with others within their specialty than they do with persons in other professions.

In the apicultural field there is one in Pennsylvania that stands pre-eminently first, and this statement reflects no injustice on the tens of thousands of bee-keepers in that state. They themselves have for over ten years regularly re-elected Prof. H. A. Surface, State Zoologist, of the Department of Agriculture, as president of their State Bee-keepers' Association. He has written a bulletin on beekeeping in Pennsylvania, which is accepted by them as authority for both theory and practice. He

is known as a practical worker as well as a thinker, writer, and speaker. No one who knows of the development of beekeeping in Pennsylvania and of the effort to preserve this industry from the destructive attacks of bee diseases will fail to say at once that Prof. Surface has been pre-eminently most conspicuous in this work. Not only is he known in Pennsylvania, but also in other states.

After an address before the New York State Beekeepers' Association the authorities of that state wrote him that the beekeepers for whom he had spoken had voted his address as the best that was given, and they desired notes from which it could be published; but as it was extemporaneous, and its merits were in part due to the stimulus received from a sympathetic audience, it was, unfortunately, impossible for them to procure it and preserve it in printed form.

We have so many different lines of eminence that we cannot speak for all; but it is certain in our mind that if the 25,000 beekeepers in Pennsylvania could vote for the most eminent man in their profession as well as the one who has been most active in other lines of agriculture, and who is best known for his general agricultural service in that state, it would be practically unanimous for their State Zoologist, H. A. Surface. We therefore take pleasure in presenting his name to Governor Brumbaugh for all honors and opportunity that can be accorded him.

Death of A. E. Manum

In the early 90's we visited Mr. A. E. Manum at his home in Bristol, Vt. He was at that time one of the most extensive beekeepers in New England if not in the whole United States. We were so well pleased with his swarm-catcher that we introduced it to the public, with the result that from that time to this it has been sold by practically every supply dealer in the United States. He was not only an extensive beekeeper in those days, but his influence extended far and wide to such an extent that beekeepers throughout his state adopted his hives and fixtures.

In late years the beekeeping world has lost track of him. It appears that the cutting of the basswoods, that had been almost his main stay, and the failure of clover caused him to go out of the business some ten or twelve years ago. For the last thirteen years he has been in Pasadena, Cal., where he spent his time in raising

fancy poultry and eucalyptus lumber. The news has just reached us that he died in Pasadena, June 26, at the ripe age of 77. Thus another one of the old veterans has passed over the line.

W. T. Falconer

In our issue for June 15, page 477, we gave a preliminary announcement of the death of W. T. Falconer, of the W. T. Falconer Mfg. Co., so well and favorably known to beekeepers all over the United States. Mr. Falconer, besides being actively engaged in the manufacture of beekeepers' supplies, was connected with a number of other large enterprises in the capacity of president, officer, or director. From a newspaper clipping announcing his death, it would appear that he was a

THE LATE W. T. FALCONER.

public-spirited man, well known and loved by all who knew him. In a business way we found him to be in every way a gentleman—fair and square, even though he was a direct competitor.

He started originally with his father at Falconer, N. Y., in the manufacture of sash, doors, and blinds. Later on he took up the manufacture of beekeepers' supplies, and finally became president of the W. T. Falconer Mfg. Co. Later on he took up the manufacture of rules and some other advertising novelties. In this he was very largely engaged. He was

connected with the Gurney Ball-bearing Co., Chautauqua Woolen Mills, the New York Oil Co., Chautauqua County Bank, and the Jamestown Street Railway Co., all of Jamestown, N. Y. Besides this he was actively identified with various fraternal organizations, and a member of the Jamestown Club. At the time of his death he was 65 years old, having rounded out an activity both in business and social circles that few men are capable of undertaking, and of which any man might be justly proud.

As we stated in our issue of June 15, the policies of the W. T. Falconer Co. will continue as before. In 1910 the firm was incorporated, and Mr. A. C. Davis, a son-in-law of Mr. Falconer, took up the active interests of the concern.

A Massachusetts Summer School of Beekeeping

What is, perhaps, the first itinerant school of beekeeping is to be held the first week in August by the Massachusetts Agricultural College, the Essex County Agricultural School co-operating.

This school is intended to be of help not only to the professional beekeeper but to market-gardeners, fruitgrowers, growers of cucumbers under glass, managers of estates and institutions, etc.

Of the instructors, Mr. Geo. W. Adams is a prominent beekeeper of Essex County, with an experience of years. Mr. F. L. Davenport is an instructor of the Essex County Agricultural School, and has charge of the beekeeping work there. Mr. Fred A. Smith is director of that school, a man well versed in beekeeping. Mr. Gladstone H. Gale is a deputy apiary inspector in Massachusetts. Dr. Burton N. Gates is head of apicultural work in Massachusetts Agricultural College.

The school will open August 4 at Hathorne, Mass., and will last for four days. Topics of lectures will be such matters as the explanation of elementary equipment, Italianizing, the necessity for bees in fruit-growing, and suggestions for honey production.

Details of arrangements and accommodations, and all inquiries, should be addressed to Mr. Fred A. Smith, director, Essex County Agricultural School, Hathorne, Mass. Applications for registration in this school should also be addressed to him.

The opportunity open to the beekeepers of Massachusetts we wish could be available for the craft throughout the nation.

Such schols as this one—short, inexpensive, yet full of instruction—insure the spread of efficiency in apiculture.

Sweet Clover will Turn a Poor Yellow Sandy Soil to Rich Black Loam

The following article appeared in the *Rural New Yorker* for July 3. It contains so much of value that we are glad to reproduce it in these columns. The legume has not made rapid progress in the old thickly populated states, mainly, we suppose, on account of a silly prejudice against it as a noxious weed; but here is a case where one farmer says 100 per cent of his farm is in sweet clover; that it will "turn a poor yellow sandy soil to rich black loam," that "stock of all kinds like sweet clover better than alfalfa;" "contains more protein and yields more tons to the acre than any other legume."

How to get these results he explains. Many another farmer in the old conservative state of New York would do well to give it a trial.

SWEEP CLOVER IN NEW YORK STATE.

I have read with pleasure F. R. Allen's sweet-clover article. His experience with it as a pasture plant agrees with mine, and mine has extended over many years; 100 per cent of my farm is in sweet clover, and I doubt if any one else in New York can say this. Mr. Allen's plan to sow the seed two years in succession is correct; after that there will be enough seed scattering off each season to keep up the stand. This makes a perennial of it, same as alfalfa. He says that he sowed 10 acres in May, 1913, that had been in corn in 1912, but does not say whether he plowed it first or not. If he did I do not see how he could have been so successful with it, as sweet clover must have a hard seed-bed. Simply disk your sod or other ground three times in the fall, not earlier than November or December (last thing before frost, so that no weeds can start up), then roll twice, so as to get the seed-bed solid. Then any time during January or February sow 20 pounds per acre of hulled seed (white only) half each way, so as to get it even on top of the ground or snow. Freezing and thawing during the winter and spring will do the rest. If he had done this with the 25-acre field he would have had a fine catch. Sweet clover will grow luxuriantly on poor sandy soil that will not produce alfalfa, clover, nor any grain crop, if treated as above, and it will turn a poor yellow sandy soil to rich black loam in less time than any other legume. There is no poorer soil in New York than the sand belt in Schenectady and Albany counties, much of it being of the "drifty" kind.

Stock here of all kinds like sweet clover better than alfalfa or any other legume, which agrees with Mr. Allen's article. As it will produce abundantly where nothing else will grow, contains more protein, and yields more tons to the acre than any other legume, why not raise it for hay as well as pasture? I believe in giving cattle the feed they like as long as it increases milk production, as this is what the farmer is after. I cut my clover about June 15, before it commences to bloom, while it is tender, taking off perhaps 1½ to two tons per acre, and then in August thrash out a seed crop worth at

least as much as six tons more of hay, as long as the price remains where it is. The yield of seed will average about three times as much as alfalfa or red clover, as sweet clover so far has no insects nor diseases of any kind, and it is worth \$15, while the other two can be bought for \$9.

Schenectady Co., N. Y. A. BLOOMINGDALE.

Some of the Fallacies of the Past; Trying to Follow every new Hive or Idea

SOME years ago GLEANINGS was criticised for advocating in some cases certain new hives and ideas. The pages of apicultural history record many a new thing that was going to revolutionize the beekeeping world. Some of them looked very promising. The divisible-brood-chamber hive, for example, occupied pages and pages of matter from 1885 to 1895. The slogan was to "handle hives instead of frames;" but to-day nearly every one has gone back to the regulation ten-frame Langstroth hive and dimensions. We say "nearly every one" because some use and like the divisible principle. Reversible frames in the early 80's in a like manner had their day, and yet there were some good things about them. Reversible hives also came up about the same time; but the reversing of either hive or frame is now nearly forgotten.

Shake or shook swarming was exploited a few years ago. There were some good things about it; and while there were many modifications of it, the old plan of shaking bees of all ages to make an artificial swarm is not practiced as it once was.

In earlier days the pollen theory occupied whole pages in the bee-journals. If we could only get rid of the pollen in the brood-nest in the fall, it was argued, there would be no dysentery and no winter losses. The fallacy of this has been shown, and to-day good stores and pollen in the outside frames are essential for early brood-rearing. Some early springs do not furnish a sufficient quantity in time.

Non-swarming hives have had their fair share of attention; and it would be unfair to say that there was nothing in some of the principles advocated; but to-day the scheme of swarm control seems to revolve about the man and method rather than the hive.

In earlier days still, there were all kinds of devices to catch the moth-miller and the moth-worm; and while the pest is still troublesome in the South, it is now the least of the beekeeper's trouble, because he knows he can handle it with a vigorous strain of bees.

Well, has any good idea been evolved in late years that was not found in the old

original Langstroth book? Yes, many of them. When Langstroth went into the apicultural field he saw the importance of mobility in the use of combs. He invented and put into use an entirely new principle; but in making a device to hold combs he went clear to the other extreme—his frames were too movable. To-day, while there are thousands and thousands who will use nothing but the old original Langstroth, the beekeeping world at large in the United States is using some form of self-spacing frame.

Langstroth, in his day, did not know much about liquid honey; but there came, shortly after, the centrifugal honey-extractor. That device has been improved year by year, until now honey can be taken with a little engine in large quantities, and at a great saving of labor. Comb foundation followed shortly after, and with it the section honey-box, separators, fences, and the modern supers for holding them. Uncapping-devices in the form of knives; improved methods of shipping bees by express and in ear lots; stronger and better-made hives; double-walled hives for wintering bees outdoors.

In the matter of hives themselves, no great and radical change has been made from the old original Langstroth except to make a simpler hive—a plain box without porticos, a simple detachable bottom-board, and a double cover.

But there are some hives that it would have been better for the beekeeping world if they had never been "born." They cost money and tons of paper, to say nothing about printer's ink, to exploit their claims. Some of these new ideas or hives have cost thousands of dollars to the users of them. Because of this the tendency seems to be to discount everything new in the form of a hive; and any man who will essay to give the beekeeping world something better, is the butt end of jokes and sarcasm, and in most cases, at least, he ought to be. Shall we therefore ignore all who attempt to put out a new idea? Nay, verily. Such a policy would have killed the Langstroth hive and frame, the honey-extractor, comb foundation, and other wonderful devices before they were born.

There is one very good rule for every one to follow—let the other fellow do the experimenting with the new hive and frame—that is, the inventor himself; then if you feel like trying the device, test it out on a very small scale. In the mean time, stick to the standard goods and to standard methods, and you will be a happier and a wiser man, with more clean cash in your pocket.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

J. E. CRANE, that wetting the joints of sections with steam looks good, p. 482 But why didn't you tell us just how? Can you do a whole box at a time? My guess would be to elevate the box so as to direct the jet of steam from beneath.

WESLEY FOSTER is such good authority that if he says spread brood as he seems to on page 436, I don't dare dispute. I wonder if it's like stimulative feeding. I don't think that ever pays here; but in Colorado it pays big, at times when without it brood-rearing would entirely cease. Does spreading brood come good at the same time? Note that he practically says it doesn't pay when nectar and pollen are plentiful.

R. F. HOLTERMANN, you have my gracious permission to go through three motions in place of one in turning a frame over, p. 491, if you want to, but time's too precious "in this locality." With my first comb I had to do it or break combs. My assistant never has done it, and she's been handling combs thirty years. Moreover, she holds a comb flat when looking for a queen, and has never broken one. Wonder why yours break.

It is not clear, according to p. 480, "whether merely introducing a queen, without shaking or dequeening, accomplishes a cure or not" in cases of European foul brood. I don't know, but I should think it might at least be a help in most cases, even if a queen of no better stock were introduced; for in most cases when a queen is introduced there is at least a little break in brood-rearing, and that break helps the bees to clean up.

THE fact, p. 433, that Mr. Chadwick's queens lay more in a year than Mr. Byer's or mine explains why they should play out sooner; but does it explain why he should have more laying workers? When a queen goes bad my bees supersede her whether she's three years or three months old, and without any laying workers either. Why shouldn't the same bees do the same thing in California? 'Speet it's that Cyprian blood. [In California, queens might play out at a time of year when conditions were not favorable for the bees to raise another. Perhaps there are no eggs in the hive; the queen dies, and laying workers would naturally follow.—Ed.]

WESLEY L. ROBERTS, p. 415, you are starting on the wrong basis when you think good is more persistent than bad. It's often,

if not generally, the other way. Also you are away off if you think that crossing, after the first cross, always means "a breaking-up of all good qualities." It means variation, and there may be good variation as well as bad. Let me give a leaf from my own experience, an experience that you cannot have had unless you're grayer than I think you are. I had blacks, pure and simple, for five years. Then I got Italians, and had a chance to compare the two side by side. No room for discussion—the Italians were far and away ahead of the blacks. Then I had crosses, not merely the first, but the tenth or more. Some were very poor; some were excellent. As to persistence, it's been a fight of 49 years against the tendency to black blood. So I feel warranted to say Italians are better, blacks more persistent.

J. E. HAND, you ask, p. 400, "Shall we resort to the abnormal condition of queenlessness with its psychological depression upon the energies of the bees, as advocated by Dr. Miller?" Evidently you don't like my idea of having the colony ten days without a laying queen, and then, in its place, you propose—exactly the same thing! For don't you see that when you give a queen-cell in place of the queen you leave them as long without a laying queen as I do? To be sure, the bees may be in a little better state of mind with a ripe cell than with young cells just begun; but I don't suppose the difference is great. The thing that turns the trick is the same in both cases; it's that ten days with no eggs laid. Let's compare. You give a cell, with the chance that in that cell there may be a virgin with a bad wing, resulting in a drone-layer, or there may be even a dead larva. I eliminate that risk by giving at the end of ten days a young laying queen. Isn't mine the safer plan? But I've tried your plan in a few cases, and it avoids all the fuss of keeping the young queen in a nucleus and then introducing her, making it, oh so much easier! that I should prefer it if I could be sure that it never involved the very thing we are both trying to avoid—swarming. Tell us that you have tried it as many as a hundred times, and that the young queen has not swarmed out in a single case, and I'll accept yours as the better plan. But I would not use either plan for the whole apiary—not for money. I'd want a few of the most promising queens left to make a record, so that out of them I could select the best to breed from.

J. E. Crane

SIFTINGS

Middlebury, Vt.

It is very dry at this time here in Vermont, June 8. We have had little rain since Feb. 25. Clover is just beginning to blossom; and what we think we need is a "splendid life-saving rain," as Grace Allen would say.

Please, Arthur, I wish you wouldn't call the bees "poor little cusses," page 455. It isn't in good form, and almost makes a lump come in my throat. I am whispering this so no one will hear what I say but just you and me.

I met our State Commissioner of Agriculture on a train last week. He informed me that he had sowed several acres of sweet clover this season, and our county agricultural agent informs me that the interest in this crop is increasing. Well it may, for our old pastures are already drying up.

I quite agree with Wesley Foster, page 356, May 1, as to the best method of treating foul brood. Almost any method in the hands of ignorant beekeepers will be liable to prove defective or worse than useless. It needs the patience of Job and perseverance of Paul to keep up the fight.

When I read that account of 1200 acres of sweet clover, page 375, May 1, I just wanted to migrate to such pleasant pastures at once; but when I turned to the next page and read Virgil Weaver's experience in taking his bees to sweet-clover fields I thought it best to hear both sides before I decided to start.

I find in traveling about that beekeepers have different ways of estimating the value of their bees. Some count the number of their hives containing bees, while others count or estimate the number of bees in a hive. It is almost needless to add that the latter class are the more successful beekeepers.

Mr. T. J. Quail thinks alfalfa never yields honey east of the Missouri River, 453, June 1, and asks the experience of other men on this question. Well, I have seen bees work on alfalfa as fast as on any other flowers right here in Vermont. As a rule, however, it does not yield much honey here in the East. It may later.

More and more dandelions every year. It does one good to look over the fields of gold in May and feel that such gold does not demoralize any one, not even the bees. The fields that were gold have since become hoary with the seed-heads. I found one plant yesterday that had over one hundred heads; and as each head had nearly 250 seeds that one plant must have had nearly 25,000 seeds—enough, if evenly distributed, to seed well half an acre. Blessings on the dandelions! They have given us this year thousands of pounds of honey that have kept the bees rearing brood in great shape.

There is a good deal of discussion this spring about the spreading of brood, and it is well. Wesley Foster tells us it should be done with care, page 436, June 1. How? I have found it sometimes advantageous to take a comb of sealed brood just beginning to hatch, and give a weaker colony and take one with a few eggs, and give to the strong one. Sometimes we may spread brood by an empty comb from the weaker colony, or shaving the cappings of honey above the brood, or at one end of the frame of brood; sometimes, again by taking away a comb of honey and giving a dry comb instead, and finally sometimes by giving a young queen.

The discussion in the May 1st and May 15th numbers of GLEANINGS as to whether the spraying of fruit-trees injures bees seems rather amusing to one who has had some experience along these lines. One of my yards I found early in May before fruit bloom in fair condition, and coming on well, the same as other yards, but at the close of the bloom I find the old bees nearly gone, and the young bees and brood dying. While all of our other yards have continued to improve, this one has gone back and is not in nearly as good condition June 1st as on May 1st. It seems pathetic to see a ring of dead brood far outside the present cluster of bees, showing where the cluster was able to rear before fruit bloom, or to see the newly hatched bees crawl out of the hive into the grass to die. Evidently the poisoned honey is stored to some extent or it would not kill the newly hatched bees. Such colonies do not recuperate readily. The honey continues to kill the brood for some time after the fruit bloom goes by. With care a part of the yard can, perhaps, be put in shape to winter; but it looks now as though many of the colonies would die out.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

Did you ever notice that the most ardent "free trader" is in favor of a tariff on his particular product? The beekeeper is no exception.

Mr. E. F. Atwater's air-drainage article, page 496, June 15, does not appeal to my sense of reason in the least. Air drainage is a term I cannot quite comprehend, to say nothing of being able to fix it in my mind as anything more than a fancy.

There is nothing that will discourage the swarming fever more than to remove the old honey from the extracting combs before the new flow begins in earnest. The fact that there is plenty of old comb honey on hand seems to satisfy their judgment that swarming is their only recourse.

Dr. Miller says, page 481, June 15, "And you cannot know the performance of a queen until she has lived through the full season"! I recently had a young queen that filled five combs full of eggs in five days from the time she started laying. That is performance enough for me.

In a discussion with my friend Mr. Bixby a few years past, I contended that I lost no more bees on a cold day when they were going three miles to the orange than those that had only half a mile to go. In this I am convinced that Mr. Bixby was right, the past season having proved to my satisfaction that the loss is considerably greater on the long-distance flight.

Mr. Scholl thinks that I should have said a young good queen, when I said that a young queen was half the battle in fighting disease and securing surplus. He adds that he has seen many young queens that were not as good as old ones, yet Mr. Scholl must admit that age puts a handicap on a man as well as a queen, and the rule must remain in favor of the young queen.

For a number of years I have been watching the work of different colonies during the time of the yielding of nectar, to satisfy myself whether or not some colonies did not gather nectar from one source while others were working on another. I have decided that such is the case, and my discussion is based on the fact that I had

one colony this season that took a fancy to hoarhound nectar while others were working on the last of the orange. The one colony filled their combs with the dark hoarhound honey while the rest were gathering the lighter.

The season has advanced far enough to be able to figure a little on its production. If all sections of southern California are to be judged by my own locality I would say that production would be no greater than last season. Indeed, it seems probable that there will be much less than last season. With 25 per cent more colonies my production will be less than last season. Swarming has been the great drawback to heavy production. With those who gave constant care to their bees this trouble was greatly reduced; but the haphazard beekeeper this season found his crop passing in swarms, and, indeed, found many of his swarms passing over the hills and far away. More ideal weather than we have had for the past six weeks could not be asked for, but the flow has been slow for all that.

I have been making some experiments in connection with the discussion last spring as to bees drawing foundation on a certain amount of sugar syrup. In this experiment I have satisfied myself that it takes almost no stores to cause foundation to be drawn to one-third its cell depth. In this I mean to say that it is not and should not be termed comb-building. Removing a super from a strong colony at the close of the main honey-flow, while there was a slow flow at hand, and replacing it with ten full sheets of foundation, I found that the colony would draw the ten sheets to one-third the cell depth in two to three days. But there they stopped abruptly, and continued to draw the cells to the finish only as they were needed to store their honey. This led me to the conclusion that there was sufficient wax in medium brood foundation to draw the cells to one-third their length. To prove my conclusions I removed the foundation at the end of the fifth day, when work had apparently stopped, except on two combs in the center, and replaced the entire super with one containing another full set of foundation. In three days this was drawn to the same length as the first; but there, again, the rush work stopped, just as before.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas.

TEXAS HONEY-CROP PROSPECTS

So far, southwest Texas reports a comparatively short crop of honey. The spring was quite unfavorable for good results, and the early flows were affected materially by the long-drawn-out cold spring weather. Huajilla and cat-claw did not give the expected yield, and in some localities were reported as having failed entirely. The yields of light honey seem very scattering over the southwest Texas territory, and of small yield. Much of this is extracted honey, as the flows were not favorable enough for comb honey. Unlike the usual condition in more favorable years, there is very little comb honey indeed offered at present.

There is hope that the mesquite will give a yield in many of the beekeeping localities where it abounds, since reports have been to the effect that it was budded quite well, and coming into bloom. Quite a number of beekeepers have expressed very little faith in a yield from this source on account of the fact that mesquite has not yielded them any honey crop for a number of years. This source has indeed been a very uncertain one for the past few years.

Throughout the central part of the state there has been considerable horsemint, and some honey is being obtained from that source. While the mesquite here too is just coming into bloom it is not of the usual profusion that obtains when there has been a yield of mesquite honey. The unfavorableness of the springtime has had its serious effect upon all kinds of vegetation and crops. Nearly everything is about a month delayed as compared with the average year. Since the "cotton belt" extends pretty well throughout all of central Texas, and since this plant comes into bloom in our immediate portion, about the middle of June, although it is a little later this year, the bees will be kept busy for some time. Cotton is one of the most certain yielders year after year, according to my experience, and I feel assured of the usual yield from it. Just now rains are very much needed throughout the greater part of this section. The cotton has not really suffered, but more abundant rains means a much more luxuriant growth of this plant. I have found that this is essential toward a good honey yield.

It is indeed difficult for a person to report for the honey-crop conditions for the

great Lone Star State without a great deal of assistance from beekeepers located in the widely different portions of the great state. For instance, I have just learned by reports from north Texas that the bees have just begun to swarm, and that one correspondent reports having hived four swarms a few days ago. This is well past the middle of June. The honey season is coming on in this part of Texas while the beekeepers of southwest Texas have long passed the swarming season and even the spring flow.

FIRE-PROOF BUILDINGS.

I have long dreamed of a fire-proof honey-house and work-shop. My present quarters have become too small, and it will soon be necessary to erect a larger building. It is my fondest hope that my dreams will all come true. There will be a basement for honey-storage purposes. This must be dry and well ventilated, and special heating apparatus will be provided so as to keep the honey from granulating in the combs.

The main reason for only partly sinking the basement below the ground line is to elevate the first floor about four feet, or about even with the beds of the wagons in use. I have found that this is quite an advantage in that it saves lots of lifting otherwise necessary. It is easier simply to set the articles to be loaded or unloaded directly from the wagon into the honey-house or vice versa.

Concrete is to be used for the main part of the construction, but in the upper stories corrugated iron will occupy the greater portion of both walls and roof. In fact, I feel like the inventor of a new wall for the building I have in view. The new idea is that of filling out the panels between the re-enforced concrete frame-work of the building, with solid walls of corrugated iron in such a way that both the ends of the upright sheets of the metal will be inserted in the concrete at the sill-line, at the joist-line above, and into the upright piers at each side of each panel. To brace these walls of corrugated panels, angle iron will be used at proper distances across their height, to which the metal will be fastened by means of wiring. The roof will be similarly fastened.

For ordinary purposes such walls as described would be good enough, but it is my intention to use metal lath and plaster on the inside of the building, applied by fastening the metal studding directly to the angle-iron bracings that hold the iron walls.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

REARING GOOD QUEENS

"I am anxious to improve my bees by rearing better queens for each of my colonies, so that better results in honey can be obtained. I noted last year that some of my colonies gave me nearly double the honey that others did. I am going to breed from the two that gave me the highest number of pounds, rearing queens from the one which gave me 179 sections of honey, and drones from the one that gave me 172 sections. Will you give me a few pointers?"

As the time for rearing good queens has arrived, the subject of rearing the best is one well worth thoughtful attention. But allow me to say that the difference in yield, which you observed among your colonies last year, might not come altogether from the work of the queen heading each colony. This I say so you need not be altogether disappointed, should the results of your determination to rear the best of queens turn out less perfect than your expectations led you to hope for.

There are few careful beekeepers but that have noticed the lack of uniformity of yield between their colonies. This may be from two or more reasons, or a combination of them. The colony giving the lesser amount may lack enough bees of the right age for gathering. The difference may lie in the nature of the bee itself. The thorough understanding of the right management of colonies to secure the best results has much to do with the yearly product in honey, and the best queens obtainable will never roll up a success where the management is faulty. A management that has no eye toward the date of blooming of the flowers in the locality will rarely give a satisfactory return for the time and labor expended, even with the best bees the world affords.

But let us look at the bee side. From talks with beekeepers during the past thirty years, I am led to think that the variation in yield averages nearly if not quite 50 per cent between the ten highest colonies and the ten lowest in the same apiary. I am also led to believe that this same proportion will hold good when applied to different apiaries in the same state. That the stock has much to do with this, there can be no question; and when apiarists fully realize the difference in stock, the question of breeding will receive

fully as much attention as is necessary for a successful management.

It is hardly necessary to argue why queens should be scientifically bred. "The survival of the fittest" will hardly develop a better bee than we have now, for she cares for nothing save the perpetuation of the species. Her aims are altogether different from those of man. How often have I heard apiarists say, "If each colony reached the high standard sometimes reached by a single colony, my honey crop would have been doubled." Careful breeding will do much toward this, and with it reduce in proportion the cost of management and equipment. This means greater profits.

There are many points to breed for, but the one most eagerly sought is greater honey production. But in breeding for profit we often run against traits that are almost a part of the bee itself; and to change that means nearly to make over the bee. For example, let us take the swarming impulse or the desire to increase. We can remove many of the conditions that tend to produce swarming, and by persistent breeding reduce this tendency to as low a point as possible. By rearing our queen-cells in colonies whose desire to supersede their queens is the uppermost thought, quite a gain can be made.

As the queen is fundamental to the colony we must have better queens. Cheaply reared queens are detrimental. Any plan is bad which keeps a queen just emerging up from one to eight days isolated from the bees in order that she may be cheaply reared and fertilized through a saving in nuclei. Virgin queens are cheap but of little value when thus kept away from the bees for five to eight days in a nucleus, so that they may be let loose as soon as a laying queen is sold, and become laying a day or two later. In this way a laying queen can be obtained every three or four days from every nucleus made by the queen-breeder.

As long as consumers insist on paying a low price for their stock, and queen-breeders advertise queens at \$50. a hundred, so long must they be content with the results of queens reared without proper care. There is too much tendency to see how many queens can be reared, rather than how many good queens. Would that there were more among our numbers like the questioner, who is "anxious to improve his bees by rearing better queens" right in his own apiary.

GENERAL CORRESPONDENCE

THE ALEXANDER-MILLER-FOWLS-TOWNSEND METHOD OF MAKING INCREASE AND KEEPING DOWN SWARMING

BY CHALON FOWLS

[In GLEANINGS for last year, page 979, was an article by Dr. C. C. Miller in reply to Mr. A. Swahn, in which he criticised some of Mr. Alexander's statements as made in the A B C and X Y Z of Bee Culture, on his method of increase. In this connection it is proper to state that the Alexander method of increase has called forth more favorable comment as well as adverse criticism than anything we ever published. Some statements made in the original article, if construed literally without poetic license, will not stand the test of experience, and to this Dr. Miller called attention in his article, page 980, 1914. Mr. J. G. Brown, formerly a member of our editorial staff, and now in Colorado, came back with a reply to Dr. Miller in our issue for Jan. 1, page 27. In this article Mr. Brown showed that he had used the Alexander method in his Colorado apiaries with considerable success. He poked a little fun at the doctor for slightly misquoting Mr. Alexander, and not allowing sufficient leeway for poetic license. Then he gave the names of several prominent Colorado beekeepers who, like himself, had used the method with a great deal of satisfaction. More discussion back and forth followed till finally an article was written by Miss Iona Fowls, who, with her sister and father, has been doing a large business in producing extracted honey for the bottling trade at Oberlin, Ohio; but instead of going into a defense of the Alexander method she told how she and her father had used a modification of the Alexander plan for keeping down swarming. Dr. Miller in his Straws, in the following issue, page 261, calls her to task for making a statement which in his experience in his locality does not prove true. Miss Fowls comes back at him in our issue for May 1, page 377, in which she says that Dr. Miller is talking about one thing and she another; and then in the last paragraph she gives Dr. Miller credit for giving the basic principle of the new method in our issue for Aug. 15, 1911. It will, therefore, be seen that in this new or old method of swarm control several have had a hand, and hence the heading of this article.]

Mr. Fowls, in the following article, in referring to the Townsend article in the *Review*, brings out one point that deserves especial emphasis right here; namely, that the ordinary shook-swarm methods take in bees of all ages, and for that reason the shake plan cannot be regarded as an unqualified success. In the first place, it does not follow nature; and in the second place it does not always work. In the Fowls modified Alexander plan he follows nature in that he makes his swarm have nothing but old bees. We believe that Mr. Fowls or Mr. Townsend or Dr. Miller (we would not now say who, but probably Mr. Fowls) has struck on a good point in making an artificial swarm that involves the principles of natural swarming.

This whole question is a most opportune and important one, and we hope that every reader of GLEANINGS will go through the discussion very carefully. If you have back volumes of GLEANINGS, and the last issue of the *Review*, you will do well to read all the articles.

We asked Mr. Fowls to repeat his method; notwithstanding it was nearly all given by his daughter in the references cited, because we believe it is one of the most important tricks of the trade that we have published in a decade. A good thing will bear repetition.

We have known Mr. Fowls for many years. He is a man who, notwithstanding his locality is a rather poor one, succeeds with his bees. He has sent his daughters through college. He has built him a beautiful home with all modern conveniences on one of the principal streets of Oberlin. He has plenty of home comforts, and, the last we knew, money in the bank—all this and more from the bees, for he has no other business. Mr. Fowls is not, therefore, a merely theoretical writer, but one who makes money from his bees in a locality that is rather mediocre. If our readers can wade through this long introduction we hope they will take pains to read his article and those of his daughter very carefully. It might be too late to try out this method yet in some localities. If so, mark it, and save it for next year. Here it is.—Ed.]

In the June number of *The Beekeepers' Review* Editor Townsend describes a method of swarm control in outyards which he worked out last year, and which he calls "Our modified Alexander plan of swarm control." Readers of GLEANINGS will find the same plan given in an article by my daughter, page 242, March 15, also page 377, May 1.

But, to return to Mr. Townsend's article, I notice he gives as a reason for abandoning the shook-swarm plan, that there is "too much absconding of swarms" to be profitable, but gives no reason for such absconding. Now, I think that, in the system we have worked out and put in practice the last three years, we have eliminated the conditions which caused the absconding in the old "shook" method.

Let us consider for a moment the difference between a natural swarm and a "shook" swarm. A natural swarm is made up of the bees old enough to fly; but a shook swarm consists of bees of all ages—nurse-bees, cell-builders, all sorts. We have made

many "shook" swarms previous to 1912 (when we adopted the new plan), and I often thought the bees acted uneasy and dissatisfied, which I attributed to the presence of so many young bees. No doubt many of these were cell-builders primed with royal jelly, which would go right to building another batch of cells.

In 1911 we had a poor season here, the bees getting just enough honey to induce them to swarm, and we practiced "shook" swarming until we became convinced that the plan was wrong in principle for the aforesaid reasons.

About this time Dr. Miller answered an inquiry in GLEANINGS, Aug. 15, page 490, 1911, explaining that the presence of queen-cells above a comb-honey super would not have enough effect on the lower story to start swarming there. Probably I got the idea from this, and the next year (1912) we put it in practice, making over forty swarms by the new plan. The next year (1913) we had a bumper crop, and the bees directed their energies to storing, so we did not need

to make as many swarms; therefore I decided to wait another year before reporting, as I wanted to try the plan out thoroughly under different conditions; so last year we made about fifty swarms by this plan, and I don't remember that we had a single failure.

As before mentioned, our plan was given in detail in the March 15th number of GLEANINGS. I will here repeat it in brief.

Having found a colony with queen-cells we begin our treatment. If the hive has a loose bottom so it (the hive) may be used as an upper story, so much the better. In this case, find the queen and place her on a comb containing but little brood and a few bees, and place in an empty hive, filling the rest of the hive with empty combs, and place on the stand after setting the hive of brood aside. Frames of foundation may be used, but are not as good. In case foundation is used I would take (in addition to the one comb with the queen and a little brood) two frames containing little or no brood from the hive of brood, first brushing off the bees so they will be with the brood. Now place a queen-excluder on the new brood-chamber and two or more extracting-supers of empty combs on top (we use shallow supers) with the hive of brood put on last. Fill any extra space with dummies and leave till the next visit in seven or eight days, when they are moved to a new stand. To insure that no young queens hatch during the time, at the time of making the change tear out the capped cells, leaving all those not capped. Of course the swarm in the lower hive will be made up of returning field bees *all old enough to fly*. It will be seen that this result is radically different than in the case with a shaken swarm with bees of all ages, and therein is the secret of its success, in my opinion.

In this connection I notice Mr. Townsend says, if he does not find the queen the first time looking them over he shakes off six frames of brood, leaving bees and queen below, and raising the brood above. It looks to me very inconsistent, for he is simply making a "shook" swarm, and I should say they would be just as likely to swarm as any "shook" swarm. In other words, it seems to me friend Townsend overlooks an important point right here; for although our methods are alike in so far as putting the brood and queen-cells in process of building beyond the intervening super, nevertheless he allows the young bees (many of which are cell-builders) to remain with the queen in some cases.

The first year I practiced this plan, there were some cases in which cells were built in the lower story; and as there often were a lot of young bees left sticking to the sides of the hive, or adhering to the two outside frames of honey sometimes left below, I believed those fellows did the work. As most of our hives have tight bottoms I was obliged to leave them on the stand, lifting the brood out to raise up. Therefore since that first year's experience I have taken more pains to get those fellows out of the lower story. Rather than leave a quantity of young bees in the hive below I would brush them out into the hive of brood to be put on top, as I feel that is much safer.

Again, referring to Mr. Townsend's article, although I attach more importance to eliminating the cell-builders below, still the rest of his management is the same as mine; and one expression of his I can heartily indorse in which he says of those bees in the top story, "They will finish up as nice a bunch of queen-cells as one wants to see."

Oberlin, Ohio.

THE "LONG IDEA" HIVE: SOME FURTHER DETAILS SUPPLEMENTING THE EDITOR'S ARTICLE ON THE SAME SUBJECT, FEB. 15

BY O. O. POPPLETON

While any one style of hives, like all other instruments used to obtain certain results, is not superior in all respects to other styles used for the same purposes, yet all may and probably do have some advantages and some disadvantages not possessed by other styles. The original Langstroth make of hives, almost identical with the present-day dovetailed hive, seems still to retain its ascendancy over other styles in ordinary use in the production of section honey; but in my own production of ex-

tracted honey it has not given me as good results or satisfaction as has the long single-story hive with deeper frames. This doesn't mean that the long hive has no faults the other does not possess, but that on the whole its advantages are greater than are its disadvantages.

I presume that I have had more practical experience with this form of hive than has any other beekeeper in this country if not in the world, having used it over forty years, while at the same time I have had

TAKING NOTES ON LARGE-SCALE BEEKEEPING

A group of students from the advanced entomology class, Ohio State University, inspecting the apiary of the A. I. Root Co., under the direction of Professor Hines. They spent a day looking over the equipment for honey-production and queen rearing. The young man at the extreme left is from South Africa; the one at the left of Professor Hines is from China.

large experience with tiered-up hives. One season I took 52,000 lbs. of honey from dovetailed hives, and have had from 10 to 75 of that form of hives in use in my apiaries during the past ten years or more. So my opportunities for thoroughly testing both forms of hives have been very full and complete.

The editor has ably described some of the features of the hive, so I will only amplify some of the points he mentioned, and suggest some others.

Of course, the first thing any one notices on first seeing the hive is its larger size or seemingly larger size. The difference in size between one of these hives, if it were set up on end, and a three-story dovetailed hive is very small indeed, and nothing less than three stories is suitable for the best success in getting extracted honey. In fact, the hive is very similar to what a three-story hive would be if laid down on side with frames changed in position.

It looks as though such a large hive would be much more difficult to move around to different locations in the apiary. Of course, compared to a single-story ten-frame hive they would be heavier; but I can handle

them easier, and with less labor, than I can even a two-story hive. I never move any hive, large or small, any distance except on a wheelbarrow or cart. I can pick up one of my large hives and put it on a wheelbarrow much easier than I can a tiered-up one that contains the same amount of honey. This is because the cleats on which the cover rests run all around and near the top of the hive instead of handholes in the center of hives; also because there is no top story to prevent the hive being close to one, so it can be lifted straighter up. This will be fully appreciated by any one who compares the ease of lifting anything heavy close to the body, or well away from it.

Again, a tall hive is much more liable to tip over forward, if the wheelbarrow happens to strike even a small obstruction, damaging the combs, raising the temper of the bees, and bringing out more or less temper from the owner. The men who helped me load on to boats always objected strongly to handling the tiered-up hives because of the extra labor and risk.

One of the principal advantages of the hive is the ease with which it can be examined. Simply remove the hive cover, move

a couple of the slats that are loosely laid over the mortises in the top-bars, and one can see at a glance the general condition of the colony—that is, how full of bees and honey. If appearances indicate that something may not be just right, with a common pocket-knife and a couple of motions one can push back enough frames so he can look into the center of the actual brood-nest to learn the real conditions. A single motion with both hands can then shove all frames to their places; replace the slats and hive-cover, and all is done, without doing any real lifting except the hive-cover.

What I have found to be a very valuable feature of this hive is that it enables one to keep so much closer watch of conditions in the hive. Whenever I extract or go through the hive for any other purpose, I can see without using either extra time or labor in doing so the exact condition of the entire colony—not guess at it, but know it. I find this is a very important point.

I very strongly advise against using any kind of shallow frame this way. I have advised all inquirers to test the method first with the Jumbo size of frames. The more compact a colony can be kept, the better; and frames that are only two inches shallower than is the Jumbo size of frames have to be spread out too much for best results. Another thing, if one wishes at any time to use the regular size of hives and frames, these Jumbo frames and combs can be easily changed to standard size with no material loss.

I have never been a believer in the use of queen-excluders except when raising queens. I have a very decided objection to confining queens to a small part of any kind of hive. I don't believe any one making a specialty of queen-raising would be pleased with these hives. If I were to do any more queen-raising I think I would use one similar in principle to Prof. Gamallo's illustrated on page 147, only with three sections instead of two. I have raised many queens for my own use by what is essentially the Doolittle method, but not so conveniently as the same work could have been done by using tiered-up hives.

The kind of bees to use in these hives is an important factor in securing best results.

Some kinds of bees will raise large quantities of brood during a heavy honey-flow. The result is much less honey during the flow, and thousands more of bees which do not reach the age for best field work until after the flow is over with. Other kinds of bees raise brood equally well during a very light flow of honey; but as soon as a heavy flow sets in it drops excessive brood-rearing

and devotes nearly all its energies to honey-storing. In this last-named character the Italians seem to excel all other races very greatly. This seems to be the reason for their great superiority over other kinds of bees, especially in the production of extracted honey. This trait of the Italians seems to be of more importance when using these large single-story hives than in the use of tiered-up hives.

Contrary to the experience of a majority of beekeepers I have not found the dark strains of Italians to give as satisfactory results as do the very light strains. I don't mean those bred for color mainly, but those bred for both color and quality. I used to select my breeding-queens from among those giving the brightest-colored bees that were also the best honey-gatherers.

One of the real objections to these hives was well stated by the editor; viz., the extra expense of the wide boards required to make them. In Iowa, some thirty or forty years ago, I made my hives myself with the aid of a small circular-saw outfit without using any wide boards at all; but these were chaff hives; and, so far as I have ever seen, they are by far the handiest and most convenient chaff hives in existence. From what I hear I judge these hives were made on much the same principle as are those lately recommended and described by Mr. Hand, but more convenient to manipulate. My brother-in-law, Mr. Milo George, of Bowling Green, Ohio, and Mr. H. S. Rouse, of New Hampton, Iowa, are now using this style of hive. When I was with my children in the state of Washington last summer we devised between us a plan of building these hives from the rough timber by the aid of small sawing-machinery. If time and use prove that we have struck on anything that may be valuable to others, I will gladly give a description after full experience.

A person's temperament also has much to do with his choosing the right method of doing any kind of work. Some men can and do get larger net incomes from a small number of acres devoted to gardening than other successful farmers do from many scores or hundreds of acres. If these same men would reverse their work, both would be unsuccessful. These large single-story hives allow of much more intensive methods than do tiered-up hives; and many persons would make a comparative failure with one and not with the other. With others the reverse would be true.

All that is written about these hives is in reference to producing extracted and not section honey.

Stuart, Fla.

AN INTRUDING COLONY OF HONEYBEES

BY EDWARD F. BIGELOW

Recently a swarm of honeybees came out and alighted on a tree. I put them in a Pearl Agnes hive, but it was evidently too small for them. I added a second super story, making three stories in all. Then the

opposite that of the tree on which the first colony had settled. I placed a hive under the cluster, shook it off, and most of the bees started to enter the hive, but, as usual, a large number remained flying. Then some

one gave the alarming cry, "Another swarm is coming out!" Sure enough, the air was filled with bees that were pouring out of the Pearl Agnes hive, which they were deserting, probably because it was too small or I had not put it in a place shady enough. This Pearl Agnes colony moved off over the other swarm, now about half in the hive. The flying bees of both colonies seemed to become confused; and the second colony, instead of clustering, went directly into the hive, thus filling that hive to overflowing.

There seemed to be a little "scrap" among them, not only in that afternoon but all the next day

after the hive had been removed to the stand, the result being many dead bees. But now, in the words of the old-fashioned novel, they are living happily ever after.

Arcadia, Sound Beach, Ct.

hive was taken from under the tree and placed on a box in the apiary.

The next forenoon another swarm came out and alighted on a fence in a direction

HONEY WITHOUT INCREASE

BY G. W. JOICE

I have been successful in both the home and out yards with the following method of securing a crop of honey every year without making any increase unless I wish it. The system is not of my own invention, but here it is just as I use it.

During feeding, the bees are all at the home yard. I take them to the outyard about May 20, and then put on the honey-board and second full-depth story. I use a Boardman feeder for spring stimulation and feed every evening about sunset a half

to a full pint of sugar syrup, a one-to-one mixture, lukewarm. As the bees come out of the cellar about the first week of April, and the white clover begins to bloom the first week in June, I have rousing colonies by that time. Preparations for swarming begin about May 15 to 20, or practically as early as settled warm weather begins. When I find eight or more frames containing brood in a ten-frame hive I remove the parent hive and place a hive containing combs or foundation on the old stand; select

The Pearl Agnes hive and Pearl Agnes, after whom the hive was named.—Photo by Edward F. Bigelow.

a frame of brood containing the queen and young larvæ from the parent hive, clipping her at the time, and placing her on the comb of brood. I put the queen with the one frame of brood in the middle of the new hive on the old stand; place a queen-excluding honey-board on the new hive (I use the wood and 7-wire board), and the old hive on this after destroying all the queen-cells.

In seven or eight days I look the upper hive through for queen-cells and destroy them. If I wish some comb honey I place a super between the two hives when white clover begins to bloom, and a week or ten days later I put it on top of both hives. The reason for first putting it between the hives is to get the bees to draw out the sections, and the reason for putting them on top is to keep them white. After the brood is all hatched from the upper hive the bees will store it full of honey, which may be taken with the extractor and the hive put away to use the following year. In this way the queen is furnished plenty of room to lay, the bees are given plenty of storage room and an abundance of brood, which, by stimulative feeding, is here in time to take advantage of the white-clover flow. I find

that I gain about 40 lbs. of extracted honey per colony, and secure about 201 lbs. more fancy comb honey per colony than where I do not follow this system, besides eliminating 98 per cent of the swarming nuisance.

WINTERING A SURPLUS OF QUEENS.

A couple of years ago I had a few short articles in *GLEANINGS* in regard to wintering a surplus of laying queens in one cluster without division-boards or queen-excluders. I have this very day two queens that laid eggs together last season working in harmony this season. I feel that there is no secret to it that I may keep from my fellow-beemen. But there is this: I sometimes fail, and cannot understand why, when at other times I succeed fully under like circumstances, conditions, and manipulations. I have wintered successfully as many as fourteen laying queens (all of the same season's rearing) in one colony. These colonies are always wintered in the cellar. I wish other readers would try the experiment and report.

The gross receipts from my two yards are about \$10 per colony. I also farm 80 acres of land. My bees are certainly great revenue-getters.

Edon, Ohio.

A western honey-distributing company's plant.

PRODUCTION OF HONEY IN THE UNITED STATES; THE NEED OF GREATER SELLING FACILITIES

BY E. R. ROOT

The last United States census shows that, outside of the cities and towns, at least \$10,000,000 worth of honey is produced annually; but I am convinced, from the evidence in hand, that the actual amount is at least twice that, or \$20,000,000. I have run across dozens and dozens of large honey-producers located up in the mountains or out on the plains, away from assessors, who stated that they had never reported the number of their colonies nor the amount of honey produced. At one of the big conventions of the country, the question was asked how many had furnished Uncle Sam a statement of the number of their bees and of their crops. The great majority had made no such statement, and, what was more, had never been asked for one. So, taking it all in all, it is probable that \$25,000,000 would not buy all the honey that is produced annually in the United States.

The increase in the number of specialists, and the decrease in the number of farmer

beekeepers on account of foul brood is resulting in more and more honey being produced.

The facilities for producing honey in the United States have been increasing year by year. While the number of beekeepers in the United States is larger than formerly, there are more persons who make the keeping of bees a specialty. There are not a few who own and operate from 1000 to 2000 and even 3000 colonies. The large producers, as a rule, are located west of the Mississippi, and particularly in the irrigated regions where alfalfa and sweet clover are grown.

So large has become the general amount produced that it brings up the problem of insufficient selling facilities. The National Beekeepers' Association touched on this question at its last session at Denver. The secretary, Mr. G. W. Williams, of Redkey, Ind., has repeatedly called attention to the fact that the selling facilities should be in-

creased to take care of this vast production. The F. W. Muth Co. and C. H. W. Weber, both of Cincinnati; the Colorado Honey-producers' Association, of Denver, Col.; the Superior Honey Co., of Ogden and Idaho Falls, Ida.; and the A. I. Root Co., if you please, are among those who have been seeking to find a market for the honey-producers of the United States. Last year, in fact, the A. I. Root Co. spent in the neighborhood of \$25,000 in newspaper and magazine advertising. All of these companies have been sending out traveling men to get honey introduced in the main avenues of trade.

THE SUPERIOR HONEY COMPANY.

One of the companies in the West that has been doing much in promoting the sale of honey is the Superior Honey Co., of Ogden, Utah, and Idaho Falls, Idaho. It is not only interested in the honey-selling business but is a large producer of honey. It owns and operates something like 3000 colonies of bees in some very fine bee territory in Utah and Idaho. This company is likewise interested in the sale of beekeepers' supplies, and also manufactures comb foundation. It is also doing a large business in buying honey, both comb and extracted. It is buying tin cans by the carload, and shipping honey all over the United States, both wholesale and retail.

The engraving shown herewith represents one of their warehouses in Ogden, Utah;

and the other, almost a duplicate of it, is located at Idaho Falls. Both buildings are of substantial brick, and the company is well organized to do a large business in buying and selling honey and in the sale of supplies for the beekeeper.

If more of the large producers who are interested in the promotion of the sale of honey, especially the introduction of it to the large avenues of trade, would do as the Superior Honey Co. is doing, there would be a better and stronger demand for honey. Already honey is now on sale in Pullman cars, at fancy restaurants, first-class groceries, and drugstores, as it was never sold before. Some day the beekeepers of the country will recognize the services a few of these concerns are doing in the line of promoting the sale of honey in lines that hitherto have been undeveloped.

I had the pleasure of visiting both of the Superior Honey Company's warehouses. I found hustling business men at both places, and evidences of a large business being carried on. I doubt very much whether the beekeepers of the Rocky Mountain districts appreciate what this company is doing in the way of extending the sale of honey. It is doing an immense business. The Ogden warehouse is in charge of the senior Redfield. The Idaho Falls branch is in charge of his brother. A brother-in-law is superintendent of the warehouses and of the manufacturing end of the business.

THE SIMMINS METHOD OF QUEEN INTRODUCTION

BY J. H. TODD

We have read a good deal lately in *GLEANINGS* about A. C. Miller's direct method of introduction with smoke; and from the varying results achieved it seems there are several essential details which must be observed to secure success. I have not personally tried it, as I nearly always use Simmins' direct method, with which I have never had a failure, and which I believe, all things considered, to be the safest and simplest method of all, especially for a beginner. I must confess I am disappointed at the remarks made on it in the A B C and X Y Z of Bee Culture. When I got the new edition, the first thing I referred to was this, only to find the same short, discouraging allusion to this valuable and infallible method of queen introduction.

May I make special allusion to three parts of this reference?

1. "It is not one (method of introduction) that we would recommend in any event to a beginner."

This I have always been at a loss to understand. I should have thought the best method for a beginner is the one where there is the best manipulation and least chance of making a mistake—in other words, the simplest. Now, what can be simpler than the Simmins method? It is of all methods the one that can be performed by rule-of-the-thumb, regardless of every condition of colony and weather, except only that the colony must be queenless, no matter for how short or how long a time. Queen-cells may be present or not—only queenlessness is necessary.

2. "And the hive closed up for 48 hours." I don't know how this came to be inserted, as I am sure Mr. Simmins did not intend the entrance to be closed; and from the footnote you clearly mean closing the entrance. I find nothing in his book about closing the entrance. He certainly gives a caution against examining the hive for 48 hours, but that is all.

I think closing the entrance is a mistake. I never have done it, and am sure it is not part of the Simmins method.

3. Then, again, in the A B C you say, "This will work safely in many cases; but we are sure there are some conditions where it does not." And now at once, as a comparison to the above, let me quote from Mr. Simmins' book, 1904 edition, page 289, an extract he gives from Mr. F. Cheshire's work on bees:

"Following up the question, I tried many dozens of experiments, and found that by Mr. Simmins' method it was quite easy, and not only to introduce, but to get one queen to lay in half a dozen distinct hives in a single week. . . . My trials have, I believe, embraced almost every supposable difficulty and variation in season and in the condition of the stocks, and show the system to be practically perfect. . . . Direct introduction as taught by Mr. Simmins has saved me queens, time, and anxiety, and I feel pleasure in expressing my indebtedness."

From the above it appears Mr. Cheshire's unqualified praise of the system is based on exhaustive experiments. Can you tell us whether the above rather discouraging quotation from the A B C is similarly based on practice, or is it merely supposition or opinion of the authors? It reads as though it were merely an opinion.

Here are the directions in the author's words:

"The three things of importance to be observed are so follows:

"1. Keep the queen quite alone for not less than 30 minutes.

"2. She is to be without food meanwhile,

"3, and to be allowed to run down from the top of the frames, after darkness has set in, by lamplight. It is also important that the same receptacle be not used twice over for holding the queen during the thirty minutes' probation without being first scalded or otherwise cleansed. Of course, a metal cage is easily made clean, though there is no objection to the cheap 'Safety' match-boxes so commonly in use, as there is nothing obnoxious about this kind. . . . Caution: Make no examination after inserting the queen, . . . until 48 hours have expired.

"The above meets all requirements, whether the colony has been long or only a short time queenless, if it has brood or not, or queen-cells in any stage of development. It is also applicable to any season of the year."

In conclusion I will add three hints from my own experience:

1. Have a good lamp so as to be sure the

queen actually goes down between two frames.

2. Take the smoker lighted just to keep back the bees that come out when the mat is lifted.

3. Make a rule of running the queen between two central combs in case the bees are not clustering at the corners of the hives, and only just uncover the ends of the frames so as to give room to run the queen down comfortably; don't pull all the mat off and make a disturbance. Do it all as quietly as possible. Use very little smoke, just to prevent the bees coming out and getting crushed when you adjust the mat again. Work as if you were in a room with a sleeping baby who must not be awakened.

Blenheim, N. Z., March 20.

[Your whole plea in favor of the Simmins method of introducing is based on a misunderstanding of an unfortunate wording which, we are frank to admit, might be construed to mean *closing the entrance of the hive*. It certainly was not so meant by us. What we intended to convey was that the hive should be closed up, meaning putting on the cover and not opening it up nor disturbing again for 48 hours. You have the idea that we intended the *entrance* should be closed. We are not sure that Mr. Miller received the same impression. If he had he would have called attention to the error. This language has been used in two different editions of the A B C and X Y Z of Bee Culture, and yet no one hitherto has read it as you do, unless it was, perhaps, A. C. Miller, as implied in his footnote. We will see that there is no ambiguity in our next edition.

You object to the word of caution where-in we state that the plan "is not one that we would recommend in the case of a valuable queen, or in any event to a beginner." Perhaps as time goes on we may modify our opinion. We are always open to conviction. But the sentence in question was not based on theory nor prejudice, as you surmise. We referred the matter at the time to the experienced men in our yards who had tried it faithfully. It would work with them, and we used it to a considerable extent; but we have lost queens by it, and yet we followed Mr. Simmins' directions to the letter; nor did we close the entrance, as you imply, for 48 hours. Further experience with the method might modify the change in the language, although it has stood thus through two different editions.

You have, perhaps, overlooked the fact that we do a business of introducing queens, day in and day out, on a large scale, per-

haps, than any other concern in the world. We have tested all methods of introducing, and are constantly testing them; and every now and then we revert back to the Simmins fasting method; but it is an unvarnished fact that we seem to be drifting back to the caging method, which is by no means perfect.

The A B C and X Y Z of Bee Culture was written primarily for beginners. Since

the first edition it has outgrown its swaddling-clothes, and is now a volume for the professional as well as for the beginner. It is one of our policies in this work to recommend nothing to the beginner that has not stood the most thorough test in our own yards or in the yards of some successful honey-producers who have had a larger experience than ourselves, and are, therefore, more competent to judge.—ED.]

SERVING THE DRINKS WITH SAFETY

BY B. C. AUTEN

Here is a watering device which I believe answers all requirements better than any other I have seen. It will furnish an abundant supply of water for a large force of bees, keeps the water pure and fresh, gives no chance for drowning the bees, and requires attention only once in several days.

punched in the side a half-inch or an inch from the bottom. The tub should be placed in position, and water be allowed to run in until it reaches the level of the outlet-hole. Then sand should be spread in the bottom and leveled up with the water until its surface is slightly above that of the water. The

Furnishes an abundant supply of water for a large force of bees.

The reservoir is one of the tanks sold by the oil companies for the storage of gasoline, capacity sixty gallons, fitted with a brass faucet and with a four-inch screw cap in the top. The reservoir is filled with water, and the faucet adjusted to a drip faster or slower, according to the number of bees.

The other part of the apparatus is a common galvanized-iron tub, with a hole

bees then stand dry-shod on the sand, and reach their tongues down into it for the water. The drip from the tank keeps up the supply, and the outlet-hole prevents the water reaching the surface of the sand.

All watering-devices using cobs, grass, cork dust, sawdust, or any other organic material, will get foul in a very few days; but with the sand, as used above, the water will never get foul.

Carthage, Mo.

FOUNDATION ECONOMY

BY C. V. CONOVER

During each of the last two seasons I used a number of supers of sections fitted with foundation cut and used as illustrated. In every case the results were equal in every respect to those obtained by using nearly full sheets of foundation and bottom starters as advocated by Dr. C. C. Miller. My plan seems to be about the one way of placing foundation in sections that is not shown or described in the A B C and X Y Z of Bee Culture.

This arrangement of foundation produced finished sections in which the comb was straight and was attached on all four sides without corner holes. There was never any trouble with buckling of foundation due to sections or foundation being out of square, or from expansion when placed on the hive, as is often the case when full or nearly full sheets are used. The foundation is not so liable to fall from accidental rough handling before it reaches the bees, as the weight on the top where it is fastened is reduced a half, and the weight remaining is concentrated nearer the line of attachment. But the advantage over Dr. Miller's plan lay in the saving of foundation which was effected. With $4\frac{1}{4} \times 4\frac{3}{4}$ sections this saving amounts to about 45 per cent of the foundation. With $4\frac{1}{2} \times 4\frac{1}{4}$ sections it would be a trifle less, as the bottom starter occupies a relatively larger portion of the space in this shape of section.

The one disadvantage was the trouble of cutting and fastening the greater number of pieces of foundation. The cutting was not a serious matter; and as I fastened all foundation with melted wax, the fixing of the extra piece of the top starter merely took a little more time in placing the pieces, but offered no further obstacle. I imagine that,

with a little ingenuity, the hot plate fasteners could be made to handle these pieces with the expenditure of a little more time on each.

I figured that the saving effected by this means, over the use of bottom starters and full top starters reaching within $\frac{1}{4}$ in. of

the bottom starter, amounted to $\frac{1}{4}$ cent per section when using extra-thin super foundation at 70 cts. per lb., and a little more than that when using thin super at 60 cts. per pound. This is not a great amount in itself, and often would be offset by the extra time necessary; but for any one who is long on time and short on money it offers an excellent opportunity to make the one take the place of the other without any sacrifice of results.

Flint, Mich.

A SIMPLE WATERING ARRANGEMENT

BY D. E. LHOMMEDIEU

When setting bees out of winter quarters I was desirous of getting them started at a watering-place close by, so they would not go to the neighbor's well. I started them by setting out wheat flour before they gathered natural pollen. They went wild on the flour. By placing the water-dishes close by they commenced to carry water too. The bees seemed to take the flour so fast I finally substituted some reddog—finely ground shorts for stock-feeding purposes. They

soon quit working, and commenced with the regular wheat flour as fast as ever.

To return to the watering, I tried putting in about a heaping teaspoonful of salt to 12 or 15 quarts of water. In some dishes I put no salt. The bees practically left the dishes that were not salted.

To devise a watering-place for 10 cts., buy a candy-pail; put in two teaspoonfuls of salt; fill with water, and cover the top with corn cobs. In a few days, when they

become water-soaked, replace with a new set; and by the time they are ready to throw out, the old ones are dry to replace them. Change the water occasionally. Fill up the pail mornings before they get to work.

With a good-sized yard you may need two or three pails scattered among the hives. I never see a bee around my pump now, only a few rods from the hives.

Colo, Iowa.

AN OBSERVATORY HIVE 100 FEET FROM THE GROUND

BY L. ESENHOWER

[One hundred feet above the sidewalk in a section of a city in Pennsylvania stands the "house-apiary" of Mr. Esenhower. The hives are situated inside a tank house on the roof of a high building. A few years ago Mr. Esenhower averaged 60 pounds per colony. Further particulars regarding the apiary were given in *GLEANINGS* for March 1, 1914.—Ed.]

The interesting feature of my house-apiary is the observatory hive. The combs are arranged vertically, one above the other, in such a shape as to present the largest surface to view.

While I have not gone into any scientific

observation, this would be an excellent opportunity for so doing. Lack of time prevents me making this observation.

The small picture shows the cluster as it appears in winter.

I think the cluster is located where it is on account of the feeder being so near. There have been many far more interesting features developed in this hive of the honeybee which would require extended writing to put them all on paper.

From the commercial standpoint it is not a success. As a novelty, it answers admirable purposes. It has been viewed by many visitors who have expressed their astonishment and admiration at so novel a contrivance.

The combs are arranged vertically.

The winter cluster.

Last year the bees stored only two combs above the brood. I intend to try a new experiment this coming season, and will be able to report later on.

We did not find brood on more than three combs, and this was for a short time only, probably not exceeding four weeks—that in the height of the season.

Reading, Pa.

SOME UNSATISFACTORY EXPERIENCE IN CURING FOUL BROOD BY THE BALDRIDGE PLAN

BY JOSEPH J. ANDERSON

Last season when I had a very heavy percentage of American foul brood among my colonies in three yards I decided to shake every colony in these yards (more than three hundred), as I hoped to get rid of the disease at one stroke. This I did at the beginning of the honey-flow. I got a fine crop of first-class honey, and about two tons of beautiful wax.

The greatest care was used in handling combs and in rendering the wax. The melting was all done during a heavy honey-flow. A few of the combs were filled with honey, this was extracted, and strong formaldehyde used in disinfecting the extractor-tank and tools. I got a splendid lot of fine new combs drawn out.

However, I made only one shaking, putting the bees on full sheets of foundation. With some of the colonies, perhaps a third, I used the modified Baldrige plan, as described in one of the June issues of *GLEANINGS* of last year. I used funnel-shaped tin tubes about 8 inches long, with the end opening only large enough to permit one bee to pass out at a time. I set the diseased hive at right angles to the new one, with the end of the tube about two inches above the entrance, according to the orthodox method. But the bees defied all rules, and passed into the hive as well as out through the tube.

In my first inspection this spring I discovered twenty-six cases among those treated last summer.

I was disposed to lay my troubles to the Baldrige plan, which I now denominate the tin-horn method, since the one yard where I did not use this plan showed no recurrence.

We have had rains, clouds, and wind the last two weeks, so that no work could be done among the bees. Three days ago, May 16, we got a few hours of sunshine, and I started to inspect the second time. I examined four and found the infection in each one—only a cell or two—but it was there sure enough. Perhaps when I get to the yard where I did not use the Baldrige plan I shall find the infection, although at the first inspection I passed all as clean.

The query I am putting to myself is this: Are my troubles due to the use of the Baldrige plan or to the single shake or both? Perhaps had I shaken twice my colonies would have been clear of the infection. My experience with foul brood teaches that,

while one knows a colony is diseased when he sees the symptoms, he can never be absolutely certain that a colony is not infected, since a single cell containing the disease may be overlooked, no matter how careful the inspection. A second inspection may reveal the trouble as in the case of the four colonies.

"Where am I?" is the big question now. If I am anywhere, how shall I proceed? I may and will treat the diseased colonies, bringing them in to the home yard where I have a cellar and other equipment for handling the infected combs.

But when I do this, am I certain no more infection exists among the rest? Shall I proceed to make my increase artificially as hitherto, thus incidentally eliminating almost absolutely all swarming? Or shall I let the bees swarm to avoid the chance of spreading disease? How much danger is there of a swarm from an infected colony developing foul brood when hived on full sheets of foundation? Of one thing I am certain, I shall do no more fooling with the Baldrige plan, modified or otherwise.

There is a strong feeling among many prominent beemen that the only efficient way of treating foul brood is to burn up brood, hive and all. But when I reflect that these men do not get rid of foul brood, but have to burn every year, I am led to believe that shaking properly done is just as effectual, and certainly far less expensive.

It seems that foul brood is with us to stay, and that it can never be completely eradicated.

A second inspection has shown thirteen cases recurring among the bees (75 colonies) above referred to, where I did not use the Baldrige plan, and 100 cases among those 160 colonies where I did use it somewhat. A mile from my two yards is an apiary where I know some foul brood has existed. Have my bees carried the disease from there after being shaken?

Salem, Idaho.

[Last winter we spent a couple of days with Mr. J. J. Anderson; and during that time we looked over two of his outyards that had been placed in winter quarters. Pictures of these will be given in September or October. It is sufficient to state that Mr. Anderson is one of the most successful comb-honey producers in the United States. The criticism cannot be made that he did not follow directions for treating foul

brood carefully, for he is precision itself. His last paragraph suggests the cause of the recurrence of the disease among his bees where he says, "A mile from my two yards is an apiary where I know foul brood has existed. Have my bees carried the disease from there after being shaken?"

In answer to the last sentence we say, probably, yes. We do not believe the recurrence of foul brood in your yards was due to the fact that there was only one shaking instead of two, or that the Baldrige plan was unsafe, although if one uses it he takes a little risk; but if we had much disease in a yard we would use it; for to destroy good brood in a strong colony is a big waste. By the Baldrige plan this is all saved, except what is actually dead or diseased.

To sum up, it is possible that some of this recurrence was due to the Baldrige plan; but we venture the assertion that 99 per cent of it, if not 100, came from the yard a mile away. If that other yard contained any old combs or hives from which the bees had died the previous winter, the

Anderson bees would be almost sure to find them; and if there was infection in them they would carry it to their own hives. It is a well-known fact that the first colonies to die in winter are those that had foul brood the previous fall. If, therefore, there were dead colonies in that yard a mile away, there is a strong probability that they contained diseased honey.

We would suggest that Mr. Anderson either buy out that yard or get his neighbor to treat it.

Years ago, when we had foul brood extensively in our home apiary, we shook only once on foundation; and we never, in all the hundred or so of colonies shaken, have had a recurrence. Dr. E. F. Phillips, of the Department of Agriculture, has told us that one shaking is ordinarily sufficient; and, if we are correct, he advises only one shaking.

We shall be glad to hear from our foul-brood inspectors—especially N. E. France, and any of the old-time inspectors in New York. If two shakings are necessary to make it sure to cure American foul brood, we are willing to be shown.—Ed.]

CARLOADS OF BEES MOVING NORTHWARD TO MEDINA

Some New Tricks in Loading Hives into a Car, whereby nearly 400 Colonies can be put into a 36-foot Car

BY E. R. ROOT

The first two carloads of bees have arrived—one from Virginia, and one from Texas. Announcements concerning the arrival of these cars appear in our issue for June 1, page 431, and June 15, page 521. Still another one will come from Virginia some time in July or August.

The aim was to get the two first cars here before the opening of clover. The first car from Virginia arrived in ample time. The second car did not arrive until June 20 on account of unfavorable weather in Texas. Mr. Harry Davenport, one of our yard men, came with both cars. The distance was considerably greater on the second car, and on account of this we arranged to put in ten barrels of water, or enough to last practically the entire trip. Giving the bees water at intervals when the weather is very warm, in the form of a spray, is very essential. A little force pump is used to throw the water on the screens where the bees cluster tightly on the wire cloth; and where the temperature seems to be high enough to be dangerous to the bees or brood a little cooling spray not only gives them a drink, but evaporation immediately lowers

the temperature. The bees will drop back from the wire cloth and go on to the combs where they should be. As soon as they get hot and roar again they are given another light spray. It can be imagined that the attendant, if the weather is very hot, has all he can do to keep the bees cool, and experience shows that he is busy both night and day. As we have before stated, traveling with a carload of bees is no Pullman job. The gas from the locomotive in going through tunnels is unpleasant to the attendant and the cinders fall on the wire-cloth screens, although we have less of this accumulation by the new method of loading, which I shall now proceed to describe.

For the convenience of the reader we will reproduce the two cuts as they appear on page 57, Jan. 15, as seen in Figs. 1 and 2. Fig. 3 shows the piles of hives and crates after they are loaded in the car. One of the crates (see Fig. 1) is placed on the car bottom, as shown in Fig. 2. As this picture was taken when the bees were moved in October, the ordinary box car was employed; but when moving the bees north, a cattle-car was used, but the method of loading is

practically the same. First a long crate is laid on the car floor, just long enough to reach up to the car door and to the end of the car. The hives are then piled on top of this crate in pairs, the back and front of the hives pointing to the back and front of the car. This leaves the rows of hives parallel to the track. As soon as the first tier of

extra colonies. Of course a doorway must be provided on the other side for entrance and egress. Ordinarily we would consider it more difficult to ship two-story than single-story, as the ventilation in the latter case would be a little better. But if one thoroughly understands his job, and the weather conditions are not too severe, he may succeed nicely with the two-story plan.

Fig. 3 shows how our first Virginia car of bees came to Medina. There is a long crate, as shown at 1 and 2; then a tier of hives; then another crate. These are piled up in alternation until the requisite height is secured. The camera shows a view looking into the doorway, and how the crate serves to let in air between each tier of hives. It will be readily seen that, by making a hive two-story, and then splitting it up at the end of the journey into two, one can save in lumber and crating, and at the same time

increase the space for bees.

In the foreground, Fig. 3, will be seen a 2x4 with notches cut in the side. We used, as far as possible, old pieces in former cars loaded on the old plan. On that plan we made a series of shelves on which several tiers of hives were placed. We had

Fig. 1.—Crating on platform ready to load.

hives is placed on the crate, another crate is put on top, and then another tier of hives, then another crate, and so on clear up to the top of the car. Four tiers like this are placed in an ordinary car. When so loaded one can get about 350 colonies in a 36-foot car. Mr. J. E. Marchant, formerly in our employ, and now with the J. E. Marchant Bee and Honey Co., says he can load 400 colonies, or, more exactly, over 200 two-story colonies, in a 36-foot car, and use only half the number of crates. He finds that the two-story hives go through in as good condition as the single-story, and the more colonies, or bees, rather, that one can get into the car, the cheaper the relative freight. The minimum weight on the 36-foot car is 14,000 lbs. Unless one can make up a shipment that will equal that minimum he is compelled to pay more freight proportionally per colony, as will be readily seen. Mr. Marchant's plan is to load the two-story colonies clear along on one side without any reference to the door. This gives room for

Fig. 2.—One section in the car ready for the hives.

supposed it might be necessary to remove a single colony from its place in the car, and give it individual treatment, or place it where it could get more air. Theoretically this was correct; but in practice it is not practicable to disturb a single colony *en route*. By piling up the hives and crating

Fig. 2.—Interior of first car of bees from Virginia, May 21, 1915, just before the work of unloading began.

like cordwood, the several tiers are locked together, and all that is necessary is to brace the individual piles from each other, and yet at the same time provide a passage for the attendant so he can water the bees by running his spray nozzle to each tier of hives.

The 2 x 4's put up on edge make it possible for the attendant to run his hand between the tiers; and if he can feel the hot breath of the bees coming up between the colonies, and he hears considerable roaring, he proceeds to give a spray. If the water runs clear down through the colony it does no particular harm, although too much dousing will kill the young brood.

Mr. Marchant, who has just brought up two carloads of bees from Apalachicola, likes this new method of piling the hives and crating like cordwood as here shown, and considers it far superior to the old way of putting up shelving that had to be strong

enough to hold a whole tier of hives, independently of the tier below. By the new method of loading, one tier of hives supports the tier above.

Moving bees by the carload is getting to be a real science, and it is now possible to take bees from the North to the South and from the South to the North without the loss of any bees or brood, providing the weather is not too hot.* The great obstacle in the way is the freight, cost of crating, and screens, as well as the transportation of attendant. So far the railroad companies do not put bees in a class where there will be any very large number of shipments from the North to the South. Moreover, they compel the shipper to pay regular railroad fare for the attendant. For all other kinds of live stock, such as horses, sheep, and

* When the last carload from Texas started it was 110 in the shade. The excessive heat and the frequent spraying to keep down the temperature killed about 20 per cent of the brood.

Fig. 4.—Unloading first car of bees from Virginia. Truck body placed on old touring car.

cattle, no charge is made for the transportation of the man in charge. By the same token, the attendant who goes with bees should not be compelled to pay regular railroad fare in addition to the freight. Unless the beekeepers of the country can get better rates, there will probably be but few car-load shipments of bees. With lower freight and the elimination of railroad fare going and coming, migratory beekeeping would be practiced to a considerable extent; for then it would be possible for the large producers to catch an early crop of honey in the South, and move northward and catch another crop; and in some rare cases, perhaps he could make three jumps; but it is not possible under existing conditions. Marked copies of this article will be sent to the leading railroad companies, and unless they will make some liberal concessions they will probably not get much more business, as we cannot stand these excessive rates. At present it costs on the average about \$2.00 per colony to take it south, and \$2.00 to move it back. One must be sure of a good crop before he undertakes to pay \$4.00 per colony to catch an extra honey-flow in the South as well as in the North. It is seldom that a crop of honey will equal that figure per colony; and were it not for the chance of making increase in the South, and a further chance of selling the bees after arriving north, the movement of bees in car lots would never be attempted, and probably will not be continued unless more

equitable rates are secured. We have already moved, up to date, nine cars; and while this is not the biggest record, perhaps we have done enough of it to believe we know something about the cost and difficulties.

Well, we will suppose the cars of bees has arrived at its destination. It is very important that complete arrangements be made in advance. As soon as the bees can be unloaded and placed on their stands for a flight, the better. If the car arrives late in the afternoon, every hive should be placed on its stand, or a temporary stand, at least before nightfall. This can be easily done by the use of one or more automobile trucks. There should be a force of strong men. Two in the car to pass out the colonies, two at each truck, and one or two men to help unload and place on their stands, would help materially. We unloaded our two last cars of bees, with the help of two trucks, in about an hour each. After the hives were all in place, and after nightfall, the entrance-screens were removed, and the bees allowed to come out. We find it better to release the bees at night rather than during the day. This can be easily done by means of a strong screwdriver and an electric pocket-light to show the exact location of the tacks that secure the entrance-screen.

In this connection it is well to explain that the bottom screen has a slot in one end of the frame. This slot is left open after the bottom screens are put on the

hives. Just before loading, these slots are closed with wire cloth. The bees should not be confined one minute longer than is necessary. If possible, bees should be loaded late in the afternoon, and, better still, after they have stopped flying. The entrance-screens are nailed just before the bees are

loaded into the car. If the bees are flying the closing will have to be deferred till night.

Fig. 4 shows one of the automobile trucks being loaded. The regular covers and bottoms should be placed first, then next the colonies themselves.

A ROTARY SECTION CLEANER

BY A. E. SHORE

A machine which will enable one to clean as many cases of honey as four men can clean by hand is that illustrated. I have been using the machine in cleaning comb honey for the Superior Honey Co., at Idaho Falls.

I sorted the honey, cleaned and cased it, and could get through about as many cases as four others could do by hand.

The illustration will show what a small power is necessary to run the little machine. Any one can soon learn to use it.

Charles R. Dana, of Ogden, cleaned ten cases an hour with this machine.

Ogden, Utah.

[While we were in Ogden last winter we had the pleasure of meeting Mr. Shore and seeing his machine which he here describes. He sent it to Medina, but we had some little trouble with it on account of its breaking the sections. But Mr. F. W. Redfield said he had seen the machine in use, and that it had been doing very satisfactory work. It has the advantage over sandpaper in that it does not clog up; and if properly used it will doubtless do good work.—Ed.]

Not an electric fan, but a section cleaner.

A QUEEN-REARING FAILURE WITH A BRIGHT SIDE

BY RUTH C. GIFFORD

My first attempt at queen-rearing was made last summer. Before starting I read everything available on the subject. Most of the methods were too complex. I wanted some good queens and also the colonies at work in supers during the clover flow. Finally I decided to rear the queens near the end of the flow; but even then I did not want to use any more colonies than were absolutely necessary.

When the time came for starting the cells, a strong colony was made broodless and queenless, as recommended in one method given in the A B C of Bee Culture. Frames containing honey were left in the hive, and the colony was allowed to stand a couple of

hours. Then it was given a frame containing eggs and young larvæ from the high-record colony. The comb in this frame was shaved back almost to the midrib on both sides. Several days later the other frames were returned, together with an extra hive of bees and brood. Everything seemed to go nicely. They built fourteen good-looking queen-cells.

The nuclei for the cells were placed in three eight-frame hives, two of which were divided into three and the other into two equal compartments. As wire screening had been tacked on the bottoms of these hives they could be placed directly over three colonies whose supers had been removed,

Little power is necessary to drive the wheel.

After the nuclei and original colony had been supplied with cells, two fine ones were left.

In caring for these a different plan was tried. Wire screening was laid on two more colonies. On that were placed upper entrances (shown in the diagram), and on each of these one regular hive-body. Then it was the work of only a few moments to fix two good nuclei with plenty of honey. Preparing these last two hives did not require nearly as much work as the others, and no holes had to be bored for entrances.

An upper entrance that is convenient and easily arranged.

The nuclei were watched carefully, and all appeared to have equal chances for rearing good queens. None of them were both-

ered by robbers. After a reasonable time they were examined. Both the two nuclei which were last made had good queens. One of the others had a kind of queen, but she hadn't laid when she was six weeks old, and so I snipped off her head. The other nuclei had no queen.

I honestly think this is an unusually bad showing for the nuclei in the hives which were divided into two and three compartments. But I'm not going to bother with them again when better results with far less work can be obtained by using one nucleus to a hive with an upper entrance. Two or three of these nucleus hives can be piled on one colony, because their entrances need not be in a straight line.

The upper entrance mentioned above is certainly convenient. It is always ready for use, and the only thing the operator has to do is to stuff the entrance proper with a clean white rag until it is the size desired. Robbers have no chance to get in the cracks at the sides of the hive. The strip of tin fastened to the sloping sticks holds them in place. Without it they shoot apart or get crooked when a hive is set on them. The wood used in the alighting-board is three-sixteenths of an inch thick. The two side pieces are both from a 1 x 3 x 16-inch strip ripped diagonally. Perhaps every one is using these entrances and has just neglected to mention them because they are so simple.

North East, Md.

NOTES FROM GERMANY

BY J. A. HEEBERLE

The teacher, W. Honzejik, reported in the *Deutsche Imker aus Bochmen* an interesting observation of bees moving eggs. He says the various instances of bees moving eggs, as reported in the contemporary bee-literature, were never convincing to him. That bees with a laying queen take eggs from one comb and carry it to another, no experienced beekeeper will believe. The following instances will prove that a queenless colony which received a fertile queen in a cage really did move eggs.

"The middle of July, 1913, in the presence of the owner, the merchant Jos. Fleischer, of Reichenberg, I examined an after-swarm that had been there before, and found it queenless. Mr. Ed Sieber, our vice-president, was also present, and gave us a young fertile queen which I took from an after-swarm and gave it to this queenless colony the same day about 4 P. M., using a sticking-cage. [These round cages are stuck into the comb with the queen, giving her a comb area of $1\frac{1}{4}$ to $1\frac{1}{2}$ inches in diameter. To liberate the queen the cage must be pulled out or the bees have to gnaw deep into the comb.]

"The queenless colony was on four large combs. I pulled the fourth comb back enough to get room for a nice comb I had selected from the comb-chest, caged the queen on it, and put it in the prepared space. Immediately after I had shoved up the comb that I had pulled back to make room for the comb with the queen on it, the colony made that peculiar humming which all practical beekeepers know means joy, and began to cover the cage. The field bees returning apparently recognized the change, delayed before the entrance, and paid honor to the royal presence by fanning, etc.

"At 2 P. M. the next day I found that the space between the comb on which the queen had been caged was thickly covered with bees, and I had to give a little smoke to get at the cage to free the queen. The liberated queen was moving very slowly, and it took her some time to get to the other side of the comb.

"I was greatly surprised to find on the side of the comb on which the queen had been imprisoned, fresh eggs. About 300 of them were placed in a circle around the cage. The cells that had been covered by the cage were free from eggs."

Mr. Honzejik says, "In this peculiar case we may assume that the fertile queen dropped the eggs, and these fell on the bottom

whence the bees gathered them up; or it is possible that the bees caught the eggs at the meshes and placed them around the cage.

"The supposition that the eggs were in the comb when it was with the queen given to the colony, or that they were from laying workers or from an overlooked queen, is in this case impossible.

The comb in question had not been in use for quite a while, and could have contained only dried-up eggs which the bees would have cleaned out as worthless. Had the eggs been from an overlooked queen or laying worker the introduced queen would have been killed; but this introduced queen was joyfully received and lovingly cared for.

"Somewhat surprising is it that the queen in the cage, although very fertile, did not deposit any eggs in the cells that were at her disposal. Did her instinct warn her to deposit eggs in a place where they could not be cared for by the bees, and where her progeny would have to perish? Possibly. Regardless of the secrets that the bees discreetly keep to themselves and thereby puzzle their keepers I affirm upon the foregoing carefully sifted material that the bees took the eggs dropped by the imprisoned queen and placed them in a circle around the cage."

DIET FOR BEES.

It is necessary for the well-being of our bees, as well as for mankind, that the food contain in sufficient quantity all the elements of which the body is built up, because they are gradually but continually changing through waste and repair, and must be repaired by a proper diet.

We know that bees winter well on cane sugar—as far as we can see—however, we cannot see very far. We conclude that sugar is good for winter food, and that may be right. As long as the bees are practically resting there is little waste and wear and tear of the bee organism.

Sugar is a carbohydrate containing only carbon, hydrogen, and oxygen. When the bees have to work as nurses or in the field nitrogenous and mineral matter must be supplied or they soon will be exhausted and succumb from deficient nutrition.

Dr. Langer-Gratz has shown that the bees furnish from their body the albumen in honey, and the nurse-bees the nitrogenous food for the young larvæ. Dr. U. Kramer, in an interesting article, "The Physiological Importance of Feeding Sugar," has shown

that, during the inversion of sugar that had been fed to the bees, albumen has been added.

Admitting the foregoing, we must conclude that nursing, inverting cane sugar in nectar, or in sugar feeding, drains the body of albumen, and that this loss must be replaced or the bees will be weakened and die prematurely. Therefore pollen is necessary to replace the nitrogenous substance the body is losing when brood-rearing is going on. It shows that sugar feeding for winter stores should be done so early in the fall that the bees can still find pollen to supply the urgent demand of the body. At the same time they get good winter stores, remain hardy, better able to resist disease, etc. Sugar is but a substitute for honey—never as good as good honey.

If the body of the bee is weakened during fall and winter from the lack of nitrogenous and mineral matter in their diet they will be less vigorous, and in spring dwindle more rapidly than they otherwise would. This is a serious impediment for development in spring. It is also doubtful whether bees whose bodies have been weakened by a deficient diet can, as nurses, raise a vigorous, long-lived progeny, since the larval food is a secretion of the nurse-bee. A weakened body succumbs more readily to the inclemency of the weather and to disease germs. The breeder and the keeper must unite to produce a healthy, vigorous, long-lived race of bees.

SOMETHING ABOUT POLLEN.

The *Bienenvater* published some interesting notes about pollen. It is gathered by the bees for its content of albumen and fat. It is a flower-like powder, differing much in color, size, and form. The size of a pollen-grain in the forget-me-not has a diameter of 0.0025 to 0.0034 millimeter; from the snakeweed, 0.010 to 0.014; lilac, 0.024 to .34; pansy, 0.062 to 0.071; cucumber, 0.20 to 0.23; melons, 0.20 to 0.24.

The flowers furnish a great amount of pollen. According to Darwin, a single dandelion has 243,000 pollen grains; one hazel-blossom has 4,000,000 grains, and one stalk of corn is estimated to furnish 50,000,000 pollen grains.

A. V. Planta has made analysis of pollen. That from the hazel showed nitrogenous matter 30.21 per cent; fettsaeuren, 4.2 per cent; pollen from the Scotch fir showed nitrogenous matter 16.6 per cent; fettsaeuren, 10.36 per cent.

A single bee takes for one load, according to Kirchner, 100,000 pollen-grains, and needs from two to eighteen minutes to complete a load.

It is very important that the bees visit usually but one kind of blossoms while gathering pollen. This habit enables them to cross-pollinate most effectually the plants. This is of great importance in the economy of nature, and is especially valuable to the fruit-grower.

Kempton, Bavaria, Germany.

BEES PREFERRING MOTH-EATEN COMBS

BY E. G. LADD

My experience has been that bees looking for a location invariably select hives that have been used. For years I have put out decoy hives, and have succeeded in inducing some to select these decoys for a future home but never yet have I had bees select a new and unused hive, although placed in good positions.

Moth-eaten combs left in old hives are often good decoys, presumably because of the scent emanating from them; but those bees choosing them have always cut out the old bad combs, building new. As for myself, I cut out all poor combs, leaving old brood-frames and sometimes good, clean, old combs. If old frames are not numerous enough by placing them together, filling the rest of the hive with new has also worked well. This is Wednesday; and on looking into a swarm that came last Saturday, and took possession of a hive that had four good

clean combs in and six new frames, I found eight full frames with brood in five, and some frames full of eggs to the edge of the comb. A super now adorns that hive, the bees immediately taking possession. These "come-to-us" bees show up for days before they finally come to stay, and sometimes in considerable quantities; and by looking at these decoy hives I can tell where to expect a new swarm. When they do come they come straight, sometimes apparently dropping down from the clouds—no settling, but with a steady rush for the entrance. They live themselves.

I have had some experience that points to the scent of bees lasting for some time—if not the scent, I should like some one to explain or otherwise. I have found if I can get the first of my swarms to alight in a good place, ninety per cent and sometimes all the following swarms will choose the

same place. This year has been a good one in that respect. The first swarm settled on a dwarf maple. Every one since has settled on the same maple, and nearly all on the same limb. Last year the first swarm alighted on a maple 40 ft. from the ground. All subsequent swarms made for the same spot until I cut it down. Now, how long can they scent the place, when the same place is chosen covering a period of weeks, and often many days apart?

My neighbor has had similar experience, and not a pleasant one. Six times his bees have settled on the chimney of his house, and each has been successfully scraped off and secured 30 feet from the ground. This same chimney was taken possession of by a fine swarm two years ago. They filled the space so that the furnace fire would not draw. Combs were started close to the top, and went down six feet. They were cut loose, and the bees finally killed. Query—can the bees of to-day smell the old leavings in that chimney that has been used for

months as a flue? Coal was burned, and surely the scent has been eradicated. Will the wiseacres please answer?

White clover is strictly to the front just now, and a steady roar all day tells a good story. Is there any music as pleasant as the roar of the bee when honey is flooding? We have the music, and dance to the tune of well-filled supers and plenty more in sight.

Portland, Oregon.

[While it is a well-recognized fact that swarms alight on limbs where previous swarms have clustered, it seems impossible to believe that the scent could cling to a chimney that had been in use that length of time; and yet the fact that six different swarms have occupied it is hard to explain except for scent. If we did not absolutely know the unquestioned veracity of the correspondent, we might think he was telling us a "fish story," especially when he adds that the last time the swarm actually impaired the draft of the chimney.—Ed.]

HOOSIER HITS

BY S. H. BURTON.

"Brown rot" would be a good name to give American foul brood.

"It's an all wind that blows nobody good." The continued rains are bringing out the white clover wonderfully; but the bees get to work on it only between showers.

D. W. Howell, page 448, June 1, I am afraid would not think so much of a shallow brood-frame "because it does not allow so much room for stores" if he had my present conditions confronting him. Colonies in full-depth Hoffman ten-frame hives are in a starving condition. All surplus stores have been used up in brood-rearing, and a recent examination at my outyards showed the bees on perfectly dry combs, and so weakened they were unable to fly. A hive as deep as the old log gums comes nearer being the ideal size.

Has anybody observed that the clipping of queens causes a plurality of eggs in each cell? Recently I clipped a very fine golden, and now find six and eight eggs in each cell, with the bees trying to supersede her. A queen uses her wings in breaking into and getting out of the cell, and the mutilation in this way is bound to have evil effects.

J. E. Crane, page 483, June 1, should keep hammering away at this great fact about the variation in bees, not only as to their superior honey-gathering qualities but their power to resist disease. Undoubtedly

nature has enabled some races or colonies to resist foul brood effectively, else there would be great danger of the race becoming extinct. We have not only found some colonies far superior to others in gathering honey, but have found in some yards every colony save one infested with foul brood. We beekeepers are not up with stock-breeders and plant-pathologists in our profession.

Washington, Ind.

[Clipping would not affect a queen's laying. Plurality of eggs in a cell is usually explained by a lack of cell room or old age in the queen. Sometimes a young queen will start laying in this way, and later lay one egg in a cell.—Ed.]

A MID-SUMMER SONG

BY GRACE ALLEN.

The mid-summer day is drunk with heat,
And the earth is a-swoon in the sun;
But the bees—oh the bees from the dawning till night
Go winging their way through an ocean of light,
Straight on to the blossoms that bloom out of sight,
And the wine of their vision is won

The warm west wind with the perfumed breath
Sinks heavily down, and is done;
But the bees are a-quiver with life as with fire!
O soul! dreaming soul of mine, why should we tire?
We too have a vision, a distant desire—
We too have the sun.

HOW SHOULD BEES, PARTICULARLY QUEEN BEES, BE SHIPPED IN POUND PACKAGES?

BY T. DWIGHT WHITMAN

Different shippers have their own ways of preparing packages of bees for shipment.

Having to make a fresh start this spring, I decided to try buying bees by the pound to avoid danger of disease. I used no old combs, and only the best of the old frames, which were dipped in boiling lye and thoroughly washed afterward in several changes of water. All hive-bodies were burned out.

The frames, after being dried in the sun, were wired, and full sheets of foundation inserted. Bees were ordered from two places in California, each distant three days by rail.

One shipper (A) used the standard Root shipping-cage with water-bottle, the queens coming loose in the boxes with the other bees. The other shipper (B) used home-made boxes with solid sides and ends with top and bottom of screen wire, a small trough for candy feed. The queen lay in a mailing-cage inside the box, and no water was supplied.

The first shipment from breeder A reached me April 5 (about ten days after date promised), at which time the plum, cherry, currant, pears, apples, and Scotch broom were in bloom. In this shipment there were eight one-pound packages (Root cages) with four untested queens loose in four marked boxes.

Colonies 1 and 2 were made of two pounds of bees with untested queens run into double hive as described in *GLEANINGS*, June 15, 1915, page 497. In each compartment of this double hive were three full frames of foundation and a division-board feeder with two cups of sugar and two of hot water.

The bees were shaken in front of this hive at 10 A. M., April 5. At noon the next day the bees had made good progress in drawing out the foundation; and the queen in No. 1 was laying. The queen in No. 2, however, did not lay until the next day. The weather conditions were as follows: April 5, very fine; 6, dull with rain at 6 P. M.; 7, showers; 8, fine; 9, very fine.

The bees in all of the boxes had consumed all of the feed, and in some of the cages the water-bottles were empty. There was quite a number of dead bees in some of the cages, those having water but no feed showing the most dead bees.

The shipment from breeder B arrived April 10. These were in home-made boxes with the queens confined in Benton cages

inside the boxes. Most of them had been released by the bees. Their supply of feed was almost used up, no water was supplied, and, to my surprise, there were very few dead bees.

These bees were put in the same kind of hive as the others. Colony No. 5 was made of two pounds of bees with an untested queen that was still in Benton cage on arrival. The hive contained the same number of frames of foundation and feeder with the same amount of feed as used before.

Weather conditions: April 10, fine and warm; 11, showers; 12, early fine, followed with showers; 13, fine, windy; 14—19, very fine.

The bees promptly drew out the foundation. Five days later, as the queen was not laying I put in a frame of drawn comb with eggs and found, on the 21st, that queen-cells had started, but the queen was not laying, and so I broke up the hive.

Colony No. 6 was made of two pounds of bees with untested queen from breeder B; but in this case she had been released from the Benton cage, while en route, by the bees. They were run in with the queen in the other side of the double hive on three full frames of foundation with division-board feeder. They were given the same feed as the others at the same time, April 10.

This queen began to lay three days later, but scattered her eggs badly, and queen-cells were started on May 5, twenty-three days later.

Other packages from breeder A gave results as follows: Nos. 3, 4, 8, 9, and 10 showed eggs in two days. Of those from breeder B, colony No. 7 showed eggs in four days but had queen-cells twenty-four days later. No. 17 had no eggs after fifteen days.

All were put in the same kind of hives on the same kind of foundation and were given the same feed and treatment.

From the results I draw the following conclusions: While water is not essential to bees in pound packages it is a benefit. Caging or confining a laying queen injures her. Shippers of bees in pound packages make a mistake where they confine the queen in Benton cages for the bees to release on the way. The better practice is to give the queen all the liberty possible and have her loose with the bees from the start. This is easily arranged by the shipper.

Tacoma, Wash.

Heads of Grain from Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

These after-swarms always reminds a feller of the things he had thought he was goin' to say, but forgot, when he made his first public speech.

Hybrids Ahead of Italians; Bisulphide of Carbon, etc.

Mr. Root:—Ants are easily vanquished by bisulphide of carbon. If in a hole in the ground, pour a little in the hole, and cover over tight. If in a nest, punch hole down in the center with cane or cart-stake, and pour, say, $\frac{1}{2}$ teacupful down it; and then if you want a little fun, wait 4 or 5 minutes; stand off as far as you can, and throw a lighted match on to it and watch your ants and uncles scatter. Be careful and not let any fire get near the bisulphide. If any of the brotherhood are troubled with woodchucks, stop up all the holes but one, then saturate a small ball of rags with bisulphide, and shove down the hole as far as possible, and stop the hole tight. Mr. Chuck won't eat any more beans.

Weevil in grain or beans can be destroyed by putting some in vessels not much too large for them, and putting some bisulphide in a saucer on top and covering the vessel tight. The fumes are heavy and go clear to the bottom.

I have one hive of hybrids that have one super of 28 sections filled and capped, and another about one-half full—say about 10 lbs. in all, while the Italians—five stands of them—have practically nothing—same treatment to all. How about it?

Wethersfield, Ct., May 18. A. N. GRISWOLD

[My friend, while it is true that hybrids occasionally outstrip full-blooded Italians, it is by no means

the rule. You may have noticed, perhaps, that in poultry the first cross frequently excels in the number of eggs and in weight either of the races from which the cross came. The principal trouble with the remedy for ants is that we cannot always find the nest readily. This is often the case in Florida and other southern localities.—A. I. R.]

How to Fill Cans

I have bought honey where the 60-lb. cans were filled as full as they could be. Whether they were weighed or not I don't know; but I suspect they were filled by some one who thought they must be filled to hold 60 lbs. Cans may vary, so it was necessary to fill them full to get in 60 lbs.

If a can is filled full, and the honey granulates, and is later melted, it will expand in melting and run over, and waste about 2 lbs. of honey, besides making a smeared mess of the outside of the can.

Some beekeepers put 58 lbs. in a can.

I wish the journals would put in their grading-rule column this sign:

Leave room in cans for honey to expand if re-liquefied. This would save some one lots of trouble and make better-satisfied customers.

Camillus, N. Y., June 7.

IRVING KINYON.

"Bob Fitzsimmons" as a Honeybee.

While observing one day the coming and going of the inhabitants of a certain hive I noticed two bees fighting fiercely, lying on their sides facing each other, and tightly clenched. Each bee was striving with all its might and skill to reach a vital part of its antagonist with its sting and desperately guarding its own body from his adversary's weapon.

Suddenly the clinch was broken, and one bee strolled nonchalantly a couple of inches toward the door of its home, while the other, which was evidently a robber bee, and as yet uninjured, righted itself squarely upon its feet. Instantly, with a tigerish spring, its enemy was upon it. An instant touch, and it was away. In less than twenty seconds the would-be burglar had paid the penalty of its crimes.

Off guard, thinking the fight was over, it was an easy victim. Talking about ring-generalship, could Bob beat that?

Gloversville, N. Y.

F. J. SHEPARD.

One More Way to Stamp Net Weight.

For branding sections with the minimum weight I use a common stamp composed of rubber letters and figures set in a hand-block similar to that ordinarily used for a rubber stamp.

The letters and figures show plainly through transparent paper. We sell these marked sections of honey from the store every day, and have very little complaint.

Bradshaw, Neb.

C. D. PALMER.

Removing Bees from Wagons

In all the articles I have read about removing bees from trees and house walls the plan was to save the colony. This is all right from the beekeeper's view, but in case of a house, the dwellers therein want to get rid of the bees at once. They do not care to wait a month, that the beekeeper may have a new colony. This was my experience.

To expedite matters I devised the following plan to relieve a friend of annoyance. I took a box of about a cubic foot capacity, and cut holes in two sides, each about three inches in diameter. Over both these I put cone bee-escapes with the apex inside. I then made a cone to go on the building and over the principal entrance. This cone was made to fit snugly into one of the cones in the box.

Trapping them going and coming. A, box; B, B, cone bee-escapes. D, hanger. E, nail to hang box on. F, space between outer and inner wall.

I hunted out all the holes by which the bees came and went, and left the main one, plugging the others with cotton scraps wet with a mixture of creolinum and petroleum. When the bees were going and coming from the one entrance I put on the cone, then hung the box so that the two cones would engage, and fastened it there.

All the bees that were afield would come and go in at one cone entrance, and the bees coming from the house would enter the box by the other; and if the box were left there any length of time the bees, of course, would perish. But one could have two boxes and change, thus saving the bees while keeping them from annoying the people in the house.

Buck Grove, Ia.

DR. A. F. BONNEY.

Every Hive Its Own Record-book

Why so much fuss and worry about keeping hive-records with crackbats, dials, books, etc?

My hives face east and are painted white. In the spring of 1913, on going over them, cleaning up, I made notations with a common No. 2 pencil on the north side, writing from top to bottom such notes as "416-1 st. s. s.," meaning that on the fourth month, 16th day, this colony had four frames of brood and was strong, but had scant stores. If I found an unclipped queen I knew she was of 1912, so drove a tack about half way in on the east side of the hive, and, of course, clipped her.

On my next round I may have made, next to my first record, such note as "53-8 c.,"—meaning

that on the fifth month, third day, I found eight frames of brood and queen-cells started; and so on through the season, making such notes as I considered necessary.

In the spring of 1914 I used the west side, and this year the south side, changing my tacks as new queens were reared. While my notes of 1913 are dim, they are still legible.

I make my notes of a size that can be read a distance of five or six feet, so that in looking over the yard I am able to see at a glance those hives which need attention. Also the notes are arranged in neat order so as not to look bad. Try it, brother beekeeper, and I am sure you will take to it.

Springfield, Mo.

E. T. BOND.

Some Physical Effects of Beestings.

While you are discussing beestings and their cures, let me give you a little of my experience. While living in Illinois, my wife's mother was stung near the temple. She broke out all over in large blotches, and was quite sick. My wife wrapped her in a wet sheet, and in about half an hour she was all right again. There were no bad effects.

I went out to Denver one morning to look after some bees. As I rode up to the house I found quite a number of people, and heard the cry of a little child. They told me she took a stick, sat down in front of a hive, and was whipping the bees. She was badly stung on the face and hands, and the people were using whisky externally and internally, I think, with the child screaming all the time. It was a very bad case, and the child might have died. There was no medical help near, nor an automobile in those days to take her to a doctor. I told them to wrap her up in a wet sheet wrung out in tepid water as quickly as they could, and bundle her up in blankets.

In twenty minutes she was laughing and entirely free of pain.

A lady friend of ours who lived in North Denver had a swarm of bees that alighted in a tree. She climbed the tree, and, without veil or gloves, cut off the limb, but spilled so many of the bees that she was badly stung on the face and hands.

She hung to her job, however, and got the bees down and hived. She then went to bed and was quite sick. She had been taking treatment for rheumatism but the ailment disappeared after she recovered from the stings.

Denver, Col.

J. L. PEABODY.

How Not to Introduce Brood Foundation.

As a novice I made one blunder against which I think I was not warned by anything I have read. My last frame of brood foundation was put in next to the division board, and now I find the bees have clustered on only one side of it to draw it out, and their weight has drawn the foundation sideways, bagging out from the wires. Aside from the evil of the bulging shape, many of the cells must be as much stretched as if it had not been wired.

I turned it around to start the bees on the other side; but I see where I shall have a comb that will not be too good to be mutilated by pushing in a cage to introduce a queen. It may have been given too soon, for the bees had hardly finished drawing out its predecessor. Perhaps if I had waited till the bees were really hungry for another frame they would have taken hold all over it; nevertheless, my next frame will go in between combs that have bees on both sides of it, whether those combs have brood or not.

Ballard Vale, Mass. STEPHEN T. BYINGTON.

A. I. Root

OUR HOMES

Editor

And God said, Let us make man in our image, after our likeness; and let them have dominion over the fish of the sea, and over the fowl of the air, and over the cattle, and over all the earth, and over every creeping thing that creepeth upon the earth. —GEN. 1:26.

In the sweat of thy face shalt thou eat bread till thou return unto the ground; for out of it wast thou taken; for dust thou art, and unto dust shalt thou return.—GEN. 3:19.

All things work together for good to them that love God.—ROMANS; 8:28.

A year ago or more somebody asked through GLEANINGS whether inventors had yet produced a gasoline motor that would run a cultivator in place of a horse; and after we had spoken of the advantages of such an invention Dr. Miller reminded us that we had not said anything about the horse stepping on our plants, especially when he turns around, etc.

There is another thing I have been thinking of. At just the right time after a rain the ground will cultivate beautifully with a light cultivator, when it is too soft for a big heavy horse to tramp through the rows. Of course, people often cultivate when it is *too* wet; but the tramping of the horse does much injury in compacting the soil unless it is very dry. By the way, this present season we have had gentle summer showers so frequently—at least in our locality—that I have as yet, July 10, had no use for our irrigating system. Well, as our garden is small, and I have strawberries, asparagus, pie-plant, and other stuff where we cannot plow, and where it is quite inconvenient for a horse to turn around without doing damage, I decided not to have a horse in the garden at all this season. So I procured one of the latest easy-running hand cultivators. It did the work finely, but it was pretty hard work unless I cultivated a few rows and then did something else to rest. Of course I could have called on one of the big stout men from the lumber-yard; but of late Mrs. Root and I both have been planning to get along by ourselves as much as possible without calling on outside help. Several times when I was too tired to run my cultivator any longer (at just the right time after a shower to have our heavy clay soil work to the best advantage) I was wondering if I could not have either electricity or gasoline to reinforce my strength. As Ernest and Huber are both tolerable experts, and pretty well posted in regard to motor electricity and gasoline motors, I interviewed them on the matter. I wanted something to furnish power, and something that was light, and which I could easily handle. Hu-

ber said there was no motor made that he knew of that weighed less than 50 lbs., for gasoline; and 50 lbs. added to my hand cultivator would make it unwieldy in turning around at the ends of the rows, and hard work to handle. He said an electric motor would do it nicely. I had in mind something for old people and boys. A boy could often do a strong man's work if he had the strength. Our readers are aware, of course, that in the great wheat-fields they have a little motor attached to the harvester. It supplements the work of the team. The team pulls the machine along, and a little gasoline-engine furnishes the power to cut the grain. The difficulty with electricity for a motor, however, is that you have got to have a storage battery or a trolley wire. The storage batteries (even Edison's latest) would be too heavy, besides the expense. A very light wire would furnish all the power needed, but we would have to go to the expense of running wires overhead, and, all together, the apparatus would be too complicated.

While we are considering this matter it may be proper to mention that the Ford people are now making something to take the place of a horse. I do not know whether it will pull a cultivator or not; but I have seen an announcement that Ford expects to have 30,000 of them on the market in September. I presume, of course, it would be too heavy and expensive for what I have in mind. With what I have been saying before you, let me submit a clipping from an excellent article in the *National Stockman and Farmer*, by our good friend W. I. Chamberlain:

It is next to folly to ask incessantly, as the non-thinkers do: "How can we keep the boys on the farm?" We don't want to keep them all on the farm. With present machinery, I repeat again, two boys growing to be men can do the work once done by ten. The other eight should and will go to the cities, the great centers of manufacture, commerce, and transportation. Four things the cities must have from the country or they will die: Pure air wafted in; pure water piped in; pure food brought in on wheels, and pure, fresh human blood drawn in by a legitimate and irresistible attraction. These vast results of science, invention, and the increased use of nature's forces are, I again insist, on the whole beneficent and only incidentally and locally disastrous. And they are irresistible. "You might as well try to dam the waters of the Nile with bulrushes" as to dam this rising tide of vast beneficence, or damn the thinkers, scientists or inventors who cause that rising tide.

After reading the above I said amen to it, and then added, "Let all unite in making our towns and cities *safer* places for the boys who leave the farm to go out in the

world. Let us *make haste* to drive out the saloons, gambling-dens, and red-light districts."

Now, with our readers' permission we will let that cultivator with its bright sharp clean hoes rest a while in the shade while we talk about something else.

When I was ten or twelve years old my father rented a pasture-lot that contained a piece of woodland, and the trees in it were mostly sugar maple. I begged the privilege of using the trees for a sugar-camp. I think there must have been thirty or forty trees. I was given a kettle, some tin pails, a sharp little ax, and told to "go ahead." And I want to tell you that one of the happiest days of my childhood was when I made sugar down in the woods just below that Mogadore pond. The rest of our family of seven were pretty sure to go down to the sugar-camp when "sugaring-off" time came. I was so careful of my utensils (of course under my good mother's directions) I produced the nicest maple sugar, stirred off white and dry (like what we call "maple cream" nowadays) that no wonder friends all around became fascinated by this spring-time industry. Some of you may recall that, years after, Professor Cook and I published a little book on maple-sugar making. Well, throughout all my life when springtime comes I have longed to get out in the sugar-camp and taste the delicious maple syrup once more. During those boyhood days we used to hunt up a little snow, if we could find it in some drift that had not entirely melted, and the hot sugar was dropped on the snow so as to make ice-cold maple wax. The great world may talk about ice-cold lemonade and other temperance drinks and the various kinds of ice cream; but to my notion nothing has ever yet—no, not even honey—equaled the God-given *new* maple sugar.

Once more, friends, I ask you to bid good-by to the *sugar-camp*, while we talk about something else.

Forty years ago or more, while working at the bench as jeweler and watchmaker I not only put in the orthodox ten hours, but twelve, fourteen, and sometimes fifteen hours. My digestion became impaired—funny, is it not? Well, I consulted a noted Cleveland specialist. He said the trouble was that everything I ate, especially fruits, fermented. He added that I was running a sort of "beer-shop" in my stomach and intestines; and from some unpleasant experiences I had been having I thought he was about right. He said I should first get outdoors, no matter what happened to the jewelry business; and this was quite an

element in getting me started in with chickens, bees, and gardening. Furthermore, he said that if I wanted to get back to health *quick* I would have to cut off all starch and sugar—everything sweet. In fact, he put me on a diet of lean meat, principally ground beefsteak; and for *eighteen weeks* I did not taste a crumb of bread nor anything but lean meat of some sort. Some of you may think this is a rather large story. In fact, my good friend Professor Cook once said, before he knew me very well, that it was impossible—a man could not *live* on lean meat alone. From an average of about 135 lbs. I went down to 112. This was when I was riding a bicycle; and when I got warmed up I had so little weight that I could go uphill and down almost like a bird. But, dear friends, the tired and exhausted feeling that I had during those eighteen weeks was terrible. After I had become warmed up by exercise I got along pretty well. Why, I have lain awake nights longing to get a taste of some moldy crackers that somebody had thrown out in the road; and when I saw red apples ripening on the trees—well, I felt as if I would give a dollar apiece for a great lot of them if I dared disobey the doctor's orders. I got over my indigestion; but I think now the outdoor exercise with a careful diet, including grain, fruit, and vegetables, would have done about as well. Under some circumstances, perhaps many, the lean-meat diet may save life; and once in a while even now I tell Mrs. Root that I shall have to get back to beefsteak for two or three meals. I do not regret this experience, for it gave me a love for fruit, grain, and other gifts of God that I should never have had otherwise.* When the doctor told me I was all right, and that I might eat what I chose, providing I was careful, one of the first things I wanted was ground wheat, and I had a grinding-mill attached to the windmill that used to make the hives long ago. My favorite dish for quite a while was boiled cracked wheat and maple sugar or good honey. I think Mrs. Root told somebody that I ate a *panful* at a meal; but she did not say how big the pan was. I soon got back to my 135 lbs.; and after a trip to California I got up to 140 lbs. Now, I tell

* Just one word about that eighteen weeks of lean-meat diet. A good many of the doctor's patients "broke over the traces." They would get real hungry for fruits and sweets, and eat them on the sly. But the doctor, with his microscope, claimed he had a method of detecting such cheats. Well, I made up my mind that I myself, and not appetite, was going to be boss. I learned self-control. I learned to be master of temper, appetite, and almost everything else. The experience has been of value to me, all my life. But, of course, again and again I fell back on my little prayer, "Lord, help."

you it is worth something to be able to enjoy the wheat, sugar, and honey as I did, after my long fast as you might call it.

Do you wonder how I am going to get my three rambling stories hitched together when they are so diverse? While I had in mind a longing for more physical strength to run that cultivator, Mrs. Root reminded me we had not had any maple sugar nor syrup since we came back from Florida; but we found some very good syrup in the market. Remembering the days of childhood I sugared off some and stirred it while cooling until it was white and had a soft fine grain. During the forenoon I ran the cultivator a little more than usual because the ground was exactly right after a summer shower. Now, a good many times when I get tired I take a nap-and then go to work again; but while sweating and thirsty, somehow I feel a great longing for some of that nice maple sugar; and while eating it it occurred to me that I had read in the government bulletin entitled "Sugar as Food," that there is quite an element of *strength* in sugar where the digestion is able to manage it. The lady who wrote the bulletin said she had watched the colored babies in the South when sugar-cane began to be ripe enough for them to chew it and suck out the juice. She said they got all over their infantile troubles, and became fat and healthy and happy all at once, under the influence of *unstinted sugar-cane juice*. I thought I would make a test to see if a good lot of maple sugar would not take the place of the motors I have been talking about to back me up with the cultivator. I guess it was a month ago that I made the experiment. I thought I would not mention it till I had given it a good test; and it rejoices my heart to be able to tell you that a good lot of nice pure maple sugar is all the motor I want. I chew it very thoroughly, and drink plenty of pure (boiled) cold water with it; and it braces me up to do a pretty fair man's work, even if I am "going on 76." In fact, I doubt if we have a man in our lumber-yard who can clean out a garden, or who *would* clean out a garden, as quick as I do it and do it well. May God be praised for sugar, and especially for maple sugar.*

* It is now July 1, several days since the above was put in type; and it is proper to say that the craving for maple sugar has gradually disappeared; but I still take a little every day—say enough to go with my strawberries and cream which I have been eating (in place of apples). If I am correct, my craving for sweets was because I have been eating so little sugar that nature called for it; and, by the way, I believe that an unperverted appetite will direct us wisely and faithfully, as a general rule, in regard to diet. My digestion is now in excellent condition. The great amount, comparatively, of maple sugar I ate daily for two or three weeks did

Just now I do not know that I enjoy anything much more than using that cultivator and my hoe in our pretty little garden. I would rather work in the garden than to travel, go to conventions, picnics, etc. There is another thing that makes me enjoy it; and that is, such work *bears fruit*. The children often caution me, telling me that so much sugar would do harm sooner or later. But the harm has not come. My digestion is better than it has been for years. Of course, we are not alike; and, still more, at different periods in our lives things agree or disagree. Some of you may ask why I say *maple* sugar. Well, I have tried cane sugar, but, for some reason I cannot understand, it does not "fill the bill." And, finally, my beekeeping friends will ask why honey does not answer. I have tried different kinds of honey, both comb and liquid, and it does not answer like the maple sugar. I do not really know why; and I am surprised to find that sugar taken *with* fruit does not seem to answer the same purpose. Maple sugar furnishes the most strength and the most perfect digestion, taken at different times during the day when I am tired and sweating. Lest you think I am getting wild, and have simply got astride of a new hobby, let me ask you to read the chipping below:

SUGAR AND THE GERMAN SOLDIER.

A German exchange reports a letter from a German soldier who is at the front in which he lauds the use of sugar. He writes: "We made some remarkable and surprising discoveries in observing ourselves and others. Even though a soldier had no liking for sugar this article became his best friend on marches and during severe cold weather. In most places that we visited the stores were 'stormed' and all the sugar was bought up. This great need for sugar, which is easily converted into muscle and heat-properties on the march and in camp, is perfectly natural. 'The particle of instinct that still survives the trying circumstances cries out for sugar, or tea heavily seasoned with sugar. And this is particularly noticeable in those who have had an aversion to sugar heretofore.'—*Louisiana Planter*."

If it were *honey* I am writing up in the way I have above, I should feel a little deli-

not impair my digestion nor interfere with my health in any way. Perhaps the physical exercise I have been taking daily has had something to do with the need for sugar.

Very likely honey will answer just as well for most people. Perhaps I might remark that maple sugar, if I am correct, is a product of the New World—America, and I believe I have read somewhere that when our forefathers first began boiling maple sap and found it would grain and make sugar there was great rejoicing; and I feel quite sure, also, that inasmuch as it does not pass through the same chemical process as does our white sugar from beet and cane, it is a more natural diet, and more wholesome. In Florida much syrup is made from different varieties of cane grown in the gardens; and I believe the people who make their own syrup in this way find it more healthful and wholesome than the sugar made in the great factories from beet and cane.

I have seen it stated somewhere that our own state of Ohio produces more maple sugar and syrup than any other state in the Union.

cate about giving it; for some of my enemies (come to think of it, I don't think I have any *real* enemies just now) who are disposed to take exceptions to these Home papers might say, "There, just see how A. I. Root is puffing his own wares." And I should hesitate, too, about giving the above to you if it were true we now deal in maple sugar and maple syrup as we did some years ago. Our present business has so increased that we were obliged to give up all outside issues, and never expect to handle the maple product again.

Our first text tells us that God planned to give man dominion over everything that grows—animal and vegetable, and we are just now beginning to wake up and take in what that promise includes. Just think of it! The oil under the ground that nobody knew anything about for ages—where would our automobiles be now were it not for this oil? and I might use a page or pages in enumerating the blessed gifts that for ages have been trodden under foot—sweet clover, for instance. We *tried* to tread it under foot, but it would not "stay down."

In regard to the second text, I cannot be happy—that is, *very* happy—unless I work at something that starts the perspiration every day of my life. In fact, it is hard for me to read your kind letters and dictate answers for an hour or two without going out into the garden. If it had not been for the "sweat of my face," I should not have discovered that the product of the maple tree is a motor to reinforce my strength in old age far better and grander, and infinitely more simple, than gasoline or even an electric motor. "All things work together for good to those who love God."

Finally, dear friends, the work that I love—in fact, I might say the greatest joy of my life at present—is hunting up God's gifts, and particularly getting in touch with others (including the Department of Agriculture), who are in a like manner developing God's wonderful precious gifts, *planned before the beginning of the world*, to bless and make happy the children whom *he* loves and the children who love *him*.

"WHERE THIEVES BREAK THROUGH AND
STEAL."

When we built our cottage just south of Bradentown, five or six years ago, our carpenter picked out a lock for the front door, that cost, I think, two or three dollars. I took it back to the hardware store to change it for a cheaper one; but the dealer thought that was just the lock we needed on such a

building. I replied, "My good friend, I agree with you that in a locality 'where thieves break through and steal' such a lock is doubtless the very thing; but here in Manatee Co., where we have never had an open saloon, and where thieves do *not* break through and steal, a cheaper and less complicated lock will be all that is needed." Although we have left our home and premises here in Bradentown for the last half-dozen summers, I have been proud to tell the people there in Ohio how safe and secure places like my own are where people spend only their winters in Florida.

With this in mind you can imagine how pained I felt to get the following letter from my good neighbor Mr. Harrison, whose home is close to my place:

Dear Mr. Root:—Wesley has just been over to tell me that some one or, rather, *two* people, visited your chickens last night. He saw where they got over the fence and scattered some feathers. It looked as though a chicken came near getting away by the looks of the ground and the feathers left there. The tracks evidently were made by men, not boys. Wesley is distracted about it. I don't see any way to head them off but to move the chickens away for a while. It would not pay to set a watch nights, because they may not come again for days or even weeks, for that matter, and yet they may come every few nights until all are taken; and if they found no one to interfere they might take the whole lot one night.

C. S. HARRISON.

Bradentown, Fla., June 26.

I hardly need tell you, good friends, that the loss of the chickens mentioned above is but a small matter—just a drop in the bucket compared with having Bradentown and Manatee Co. lose the good reputation it has enjoyed for so many years; and, more than that, letting the culprit go unrebuked for his foolish invasion of our premises. Up here in Ohio it is a penitentiary offense for stealing chickens. I do not know how it is in Florida; but it is of much importance that little acts like these should be restrained at the outset. All good Christian men and women should unite in helping to discourage this sort of pilfering, and encourage law enforcement, if nothing else will answer.

I have repeatedly spoken of the good habits and good behavior of the colored people of Manatee Co., contrasted with other places; and, in fact, at just about the time this happened I made the following mention in our journal of the state of affairs in our neighborhood:

Let me repeat what I have said about Manatee Co., Florida. There has never been a saloon in that county, and God helping us, there never will be one. As a result, my good neighbor Mr. Rood had a poultry-house undisturbed for years right up against the fence along the highway. A passerby could, in fact, reach through and get a chicken if he wanted to, and yet our population is largely *colored people*

whose loose habits and fondness for "chicken" have been proverbial.

There is still another aspect to the matter. If the one who is guilty of this act could be kindly taken in hand he might repent and never be guilty of the same act again. Remember the beautiful promise, "He which converteth the sinner from the error of his way shall save a soul from death, and shall hide a multitude of sins."

Later.—After the above was in type Wesley sent me the following:

I've moved all the chickens over to Mr. Rood's. There are 35 old laying hens and 35 young chickens I took to Mr. Rood's, and those are what are left. There were 7 ducks left also. Mr. Rood says if they had been left there every one of them would have been taken. Chickens are being stolen all over the whole neighborhood.

Manatee, Fla., June 29. WESLEY WELCH.

From the above it appears that between forty and fifty of my chickens were stolen, mostly old hens. Well, if such things must go on, it is no more than fair that I should have my share of it. I cannot now recall that during the past sixty years during which I have had more or less to do with chickens I have ever had any stolen before, although I have had frequent reports from others who have lost in that way. Not only for the good of the hard-working people who are deprived

of their honest earnings, but that this sort of pilfering may be checked at the outset, will it not be well for poultrymen to combine and form an organization such as we used to have years ago when horse thieves were so common? If it is true, as Wesley states, that the whole neighborhood is suffering from the loss of chickens, it behooves us to combine, and in that way I feel sure we can ferret out the guilty ones. I will gladly do my part, both in time and money.

My good friend W. P. Root just informs me that over sixty years ago the farmers of this county, and Wayne on the south, formed what is still known as the "Union Perseverance Company for the Detection and Apprehension of Horse Thieves;" and so effectual was this company that they claim no thief ever yet escaped their clutches. Aided now by the telephone, horse-stealing is a thing of the past in this section.

Perhaps, dear friends, there is a providence in the loss of my forty or fifty chickens. It reminds us to wake up and look after transgressors.

Would it not be in line for the Sunday-schools, the Endeavor societies, and the Y. M. C. A. to take hold of this sort of missionary work?

HIGH-PRESSURE GARDENING

CORN-PLANTING, ETC.

We are raising some pretty good corn here on our own premises; but scarcely a season passes but that I learn some lessons and see where I have blundered. To illustrate:

Our ground was nicely fitted. Our seed corn was so carefully saved and tested that I threw out only three ears from 100; and as our two old hand corn-planters did not work just to suit me, I bought a brand-new one, and our three acres of corn was to be planted with this one planter; but when the man got about half through the field Mr. Calvert, noticing a storm coming up, borrowed two more planters of a neighbor, and set two extra men planting. As a result, the corn was all in nicely just before the big drops of rain came, and we were congratulating ourselves that we had managed so nicely. Well, when the corn began to come up we were worried sometimes by finding six or seven stalks in hills planted with the borrowed corn-planters; and, in fact, all through the field there are more or less hills having five or six stalks. I believe it is

pretty well decided that, even if it is a big job, it pays to go through a cornfield and pull out all over four stalks in a hill. I think some claim there should not be more than three stalks.

Now, I have a confession to make on my part. I know there are sieves in the market to screen out all the small grains; but with our small field of corn I decided it would not pay. But what do you think it cost to go over that field and thin it down to three or four stalks in a hill? Well, it cost enough to buy two more brand-new planters, and perhaps a sieve to sort the grains as well.

There is another thing that can be done and should be done. After each ear of your seed corn has been tested for germination, pick out all the ears having the largest kernels, and put them by themselves. Pick out those having the smallest grains in the same way, and make two if not three grades. When you begin planting, adjust your planter to drop three or four grains of the large size. When the large size is gone, adjust the planter for the medium size, and, lastly, the small grains or give them to the

chickens, which, perhaps, would be the best way. I suppose these boy corn-growers have been all over the above, and are probably better posted than I am.

There is one more point that might be considered right here. One of our experiment stations, by means of a suitable sieve, or by hand sorting, picked out the largest seed corn, wheat, beans, and a whole lot of other things. They tested the large seed side by side with the small or inferior seed. If I recall correctly, the big seed by the same treatment gave almost double the crop. I think there were some exceptions to this result; but the decision was strongly in favor of using the very best seed obtainable whatever you undertake to grow; for "whatsoever a man soweth, that shall he also reap."

FETERITA AS CHICKEN FEED.

Since the article on page 558 was printed I have received pictures of my *feterita* in Florida. One of them shows the *feterita* higher than a man's head, and yet the seed had been planted only about 45 days; and I think that in 60 days, with good warm weather, especially with good warm weather *at the start*, you can have grain fit to feed to the chickens; and if you have a hot dry time the *feterita* will not mind it very much. The other non-saccharine sorghum (*kaoliang*) may do better still, but the seed is much smaller. It is now making a tremendous growth here in our Medina soil. From the above you will see there is plenty of time now to sow or plant either of the above and get a crop of grain before the frost will hurt it. *Feterita* seed is advertised in our various catalogs. If you want just a few grains for experiment I will send you some of either, free of charge.

SQUASH-BUGS — ESPECIALLY THE YELLOW STRIPED VARIETY.

This year, as well as last, we have had a regular pitched battle for the last two weeks in trying to save our melon and squash plants. Just as it was last year, the first I saw them was on Sunday morning. They came in a swarm, and would have had my nice thrifty vines, just coming out of the ground, chewed up before night. I went and got my wire-cloth baskets, such as I used last year, and pushed the edges of them down into the ground, and made everything tight, as I supposed. But the bugs were either hidden down in the dirt, near the roots of the plants, or they hatched out in the ground. Perhaps some of our readers can tell me if the latter is possible. As I did not have baskets enough to cover them all, I tried moth-balls, which seemed to suc-

ceed so well last year. But this time they paid but little or no attention to them. After the vines—especially the squash-vines—got so large they were cramped and crowded in the wire baskets, I was obliged to take them off, and then I commenced picking by hand. The bugs fly so quickly that it is a pretty hard matter for an old man to catch them before they are gone. But I crushed them up between my thumb and fingers, and dropped their mutilated bodies among the plants, hoping the rest would take warning.* Finally I read in one of the seed catalogs that *tobacco dust* would do the business. At first it seemed to keep them away; but they soon became used to the tobacco, and I was afraid the tobacco dust would eventually cost almost as much as my melons and squashes would amount to.

Well, my plants were finally so badly mutilated that I decided they would never amount to much unless they had some extra care and manure. So I procured some old black rotten stable manure containing quite a little cow manure. I scraped away the dirt from the plants so as to get down near the roots; and, even if my compost was rather bad-smelling, I spread it around all my plants, then covered the manure with nice mellow soil in order to prevent evaporation. What do you think? There was no more trouble from the bugs; but in going over my twenty or thirty hills, by mistake I missed one. Next day there was not a bug on any of the plants where I had placed the manure; but on the one plant that was skipped by accident it was almost literally alive with them. I think somebody said a while ago, through GLEANINGS, that old rotten cow manure (or it may be *fresh* manure) would keep off the bugs; but I had forgotten it. After I had got it all done, Mrs. Root suggested that if I had put a fair-sized shovelful of it into each hill, well mixed with the soil before I planted the seeds, perhaps I should not have had any two-weeks' fight on my hands. Summing it all up, my experience is that these bugs are repelled by any strong odor or perfume.

* By the way, when you do not have very many plants, hand picking is perhaps the surest and simplest method. When the bugs are at their worst it may be necessary to get around and pick them off the plants every two or three hours; and if this is followed up faithfully they will soon give up the job. When they get the impression that the owner is going to get around about once in so often they will soon decide that it is unhealthy business and move off into some other garden. Some of you may recall that in our potato-book Terry insists that hand picking is the cheapest and simplest way to get rid of the Colorado potato-bettle, and that is just what I am doing now. I caught the mother-bugs when they first made their appearance, and it was not a big task either. I do not like poisons of any kind if we can manage to get along without them.

It does not make much difference whether it is moth-balls, strong tobacco dust, or foul-smelling stable manure.

KAOLIANG; A NEW GROUP OF GRAIN SORGHUMS.

The above is the title of a 64-page bulletin, quite well illustrated, from the Department of Agriculture. It appears from the summary that there are 27 distinct varieties of kaoliang; and more or less of them have been tested in the United States for a number of years past. The Department also sent me one pound of seed. It was planted June 16, and to-day, the 21st, it is up very nicely. These grain sorghums are tremendous growers when the weather is favorable. We happened to have quite warm weather and warm rains after the seed was planted. The seed is quite a little smaller than that of *feterita*; but it cooks much quicker—at least the sample sent me did, and it tastes very much like *feterita*. We copy the following from Mr. Meyer, who was sent by the Department to China to investigate:

Of the many crops the Chinese grow in North China, the sorghum is unmistakably the most important and the most useful. Without it life in a great part of North China and Manchuria would be almost impossible, for the variety of uses to which the kaoliang is put are legion, and it could not very well be replaced by any other single crop.

The light-colored varieties are ground into flour, out of which cakes are made, or they are simply boiled in water and served in the form of a gruel to the Chinese laborers, and it is amazing to see how much a Chinese can eat of it. I have seen my own interpreter eat three big bowlfuls for breakfast in the early morning and still feel comfortable. As a feed for horses and mules one certainly can say that the kaoliang seeds, especially the dark-colored ones, in North China and Manchuria, take the same place that oats do with us.

The stalks of kaoliang are almost as valuable to the Chinese as the grain itself. In the semiarid north, where all of the wild arboreal vegetation has either been exterminated, or at least has been reduced to such an extent as not to form an important item any longer, one finds that the stalks are the chief supply of fuel. They are used to cook the food, to heat the brick bedsteads in winter time, to boil the water for tea; in fact, are used whenever heat is needed. Another important role they play is in the fine fencing material they furnish. In North China, in winter time, the icy wind blows with great violence all over the plains. To protect themselves, at the approach of the cold season the Chinese build fences around their houses, yards, pig-pens, etc., and comfort would certainly be still more reduced in North China if these kaoliang-stem windbreaks were unobtainable.

These stalks are used also as supports for plants in the vegetable gardens. They serve as poles for beans, cucumbers, and yams. They also lend themselves to basket and matting making, and in Shantung I even observed highly colored varieties that were grown for the express purpose of furnishing fancy basket and matting materials. In making the finer qualities of baskets the outer skin only is used, being split off by hand and woven into the various articles desired by skilled men and women.

For large coarse baskets, however, the whole stems are taken while they are still fresh, for when once dry they cannot be manipulated very well.

Still another use the Chinese have for these stems is to chop them up, mix them with a few handfuls of boiled black-*soy* beans, or kaoliang seeds, or bean cake, and serve them to their hard-working horses, mules, and donkeys—in the greater part of North China about the only food the draft animals ever get.

One would think by this time that the list of uses for the stems was pretty nearly exhausted, but there are still a few more; for instance, when an ordinary Chinese laborer builds himself a home he first erects a frame of poplar and willow poles; between these he places kaoliang stems. The whole frame is then smeared over with mud, in which chopped-up straw or hair has been mixed, and the house is then ready to move into. In the primitive greenhouses of the Chinese these sorghum stems serve as bars to hold the paper windows. They also constitute the frame of the roof upon which the clay is smeared.

There are several minor uses yet for these stems, such as frames for kites, paper animals, playthings for children, etc., but I am afraid that the list would be too long to add here.

A last item about the kaoliang: Even the roots are not allowed to stay in the ground, but are carefully grubbed out by a stroke of a peculiar hoe or grub and a pull with one hand, are dried, stacked up in bundles, and sold and used all over the land for fuel. One certainly might ask, what would the farmer of North China do if he had no kaoliang to fall back upon?

My impression is just now that, as *feterita* has a much larger grain, and is a much greater yielder, it will be found more profitable. But it may be that kaoliang is going to be superior as a food product. Below is a report from our friend Mr. Harrison, just at hand:

Friend Root:—I am sending you four heads of *feterita*, one each of Egyptian wheat, and chicken corn. Your garden is looking fine. Some *feterita* planted since you went away is 4 ft. tall. Wesley also planted some sweet corn that was given me, that is beginning to tassel and silk. It is about 4 ft. high. Everything is looking correspondingly well. The chickens like the *feterita* better than corn. The birds like it also.

Bradentown, Fla., June 16. C. L. HARRISON.

The *feterita* that was planted after I left must have made a growth of four feet in a little over forty days. The fact that chickens prefer it to corn is also in its favor. I have instructed Wesley to gather the heads and give them to the chickens every day. As the *feterita* is close by their yards it will make a very short cut from producer to consumer; and, if I am correct, if the heads are cut off as fast as they are fit for food, new heads will keep coming right along from the suckers. The Egyptian wheat and chicken corn also resemble *feterita*, but the grains are very much smaller. The chicken corn is, no doubt, a splendid feed for small chickens.

Later.—I have just received word from Wesley that he has been feeding *feterita* to the chickens for the past two weeks; and he says there will soon be a second crop grown from the numerous suckers.

FETERITA FOR CHICKEN FEED.

The following from our good friend Ault, of Bradentown, will explain itself:

Your feterita is great. Wesley has been cutting the ripe heads, and wherever a head has been cut one, two, or three more are putting out. The feterita will, no doubt, greatly reduce your feed bill.

JABOTICABA, THE "GRAPE OF BRAZIL."

As this new fruit-tree is receiving considerable attention, not only in Florida, California, Texas, but in other warm climates, I have thought best to give the clipping below, taken from the *Florida Grower*; but, as I understand it, the article was written by a Mr. Popenoe, sent out by the Department of Agriculture to hunt up new and valuable plants. On page 473, June 1, I spoke of the two little trees we have in our Florida garden.

Among the many indigenous fruits of Central and Southern Brazil, few create so strong an impression on the new comer as the jaboticaba, not only because of its habit of producing its deciduous fruit on the trunk of the tree from the ground up, but also because of the unusual beauty of its symmetrical, dense, umbrageous head of light-green foliage, which entitles it to a place among the best ornamental trees of the region.

The tree is generally considered the handsomest of all the *Myrtaceae*. Under favorable conditions it grows to a height of 35 or 40 feet, the trunk nearly always branching close to the ground. The leaves are opposite, ovate-elliptical to lanceolate, acute at the apex, generally glabrous, with the margins entire. They vary from three-fourths of an inch to over three inches in length, their size being one of the characters by which the different horticultural forms are distinguished. The flowers are small white, produced in clusters on the bark from the base of the trunk to the ends of the smaller branches, sometimes so thick as almost to hide the trunk from view. In form they resemble those of the myrtle, with four small petals and a prominent cluster of stamens. The normal season of flowering is said to vary with the different species, although it is quite a common occurrence for the trees to flower and fruit several times during the year, when they are in cultivation and supplied with an abundance of water.

The fruit, which develops rapidly, and ripens within two or three months after the time of flowering, is round or slightly oblate, half an inch to an inch and a half in diameter, deep, glossy maroon-purple in color, crowned with a small disk at the apex. White, sessile, or nearly so, in some varieties, in certain others the fruits are produced upon slender peduncles, not over one inch in length. Between the two extremes in size there are many gradations, those considered the largest usually found in the markets, averaging about an inch in diameter. The skin is thicker than that of the grape, and considerably tougher. It contains, besides coloring matter, a large amount of tannin. The translucent, juicy pulp, white or tinged with rose, is of a most agreeable vinous flavor, suggestive of the rotundifolia type of grape. This similarity to the grape is not confined to the flavor alone, the external appearance, character of the flesh, the size and number of seeds, as well as the flavor, all bearing such a striking resemblance to the grape as to have earned for the jaboticaba the title of the "grape of Brazil." A good jaboticaba is so thoroughly agreeable as to tempt one to keep on picking and eating the fruits indefinitely,

a temptation to which strangers as well as Brazilians often yield.

The fruiting habits of the jaboticaba are somewhat unusual. When heavily laden the tree is a curious sight. Not only is the trunk covered with clusters and masses of glistening jaboticabas but the fruiting extends to the ends of the smaller branches, which all produce their share of the crop. When one stops to consider the small size of the fruits and their abundance all over the tree, it is apparent that the numbers produced by a tree of large size much be enormous. While the fruit is adapted to a number of different uses, at present most of it is consumed in the fresh state, frequently direct from the tree.

In Brazil, propagation seems to be exclusively by seed, although the foreman of one of the principal nurseries in Rio de Janeiro stated that he had successfully inarched young trees, and considered this a desirable way to perpetuate choice varieties.

"SUGAR AND ITS VALUE AS A FOOD."

The above is the title of Farmers' Bulletin No. 535, containing 32 pages, written by Mrs. Mary Hinman Abel. From it I make the following extracts:

The addition of sugar to an ordinary or to a meager diet also considerably increased the capacity for work, the effect of the sugar being felt about a half hour after eating it, and its maximum effect showing itself two hours after eating. The coming of fatigue was also found to be considerably delayed on this diet, and taking 3 or 4 ounces of sugar a short time before the usual time for the occurrence of fatigue prevented the appearance of it.

It is true that the harvester, lumberman, and others who do hard work in the open air consume great amounts of food containing considerable quantities of sugar, such as pie and doughnuts, and apparently with impunity; but it is equally true that people living an indoor life and that undue amounts of pie, cake, and pudding, with highly sweetened preserved fruit, and sugar in large amounts on cooked cereals, almost always bring indigestion sooner or later.

Sugar is a useful and valuable food. It must, however, be remembered that it is a concentrated food, and therefore should be eaten in moderate quantities. Further, like other concentrated foods, sugar seems best fitted for assimilation by the body when supplied with other materials which dilute it or give it the necessary bulk.

You will notice it comes in very nicely with what I said in the Home papers in this issue.

NO BEES, NO HOME, YET WANTS GLEANINGS AND THE HOME DEPARTMENT.

I am both a librarian and a social worker, with little spare time, no home, and no bees; but I have loved bees and wondered at them as far back as I can remember; and it was a joy to stumble across such a completely satisfactory current study of bees as GLEANINGS one day in a seedsman's store. However, what has made me really miss the little magazine is the warm friendliness and good comradeship that makes itself quite evident in spite of the impersonality and coldness of print. They have often been an inspiration and a comfort to me. I shall be very glad to be back in the circle around the editorial easy chair of Mr. Root's Home department and Dr. Miller's Stray Straws, Mr. Doolittle's Conversations, and the other good editor-friends, as well as among the interested listeners of the words of the occasional article-writer friends.

Southern Headquarters for Italian Queens

Photo of W. D. Achord of Fitzpatrick, Ala., with helpers, also his queen-rearing yard. Queen-house and residence in background. With six experienced men, and 600 mating-boxes, also 700 full colonies of pure Italian bees, we are able to give good queens and prompt service. Untested queens, 1 to 11, 50 cts. each; 12 and more, 45 cts. each. Tested, \$1.00 each. No disease. Pure mating and safe delivery I guarantee.

EDITORIALS

Our Cover Picture

Is there a more fascinating part of bee-keeping than the study of the flowers on which the bees depend for their honey? And is any part of this study more entrancing than the photographing of such blossoms? We are proud of the illustrations in this special number, although we wish that all of our readers might see the clearness of detail contained in the original photographs.

Our cover picture, representing the wild hawthorn, is the work of Wesley Foster, whose article appears on page 619.

Quarantine on Shipments of Bees in Nevada

THE governor of Nevada has recently issued a proclamation establishing a quarantine against all states for the shipment of colonies of bees unless accompanied by a certificate from a duly appointed state or county inspector. This does not prevent proper interchange in bees, but it will prevent the shipment of bees in car lots or in small lots from irresponsible parties from other states who have the disease. It would appear that the beekeepers in Nevada appealed to the governor, with the results stated.

The Net-weight Law, and its Effect on the Comb-honey Business

EVIDENCE is beginning to accumulate, showing that a great many do not understand the net-weight law. They are afraid of it; and this very ignorance of its provisions, as well as the knowledge of them, is causing many to give up the production of comb honey.

We also find that some are going into the production of chunk comb honey in pails. This may be right in some localities; but we believe it will be a serious mistake to foist that kind of honey on the northern markets. As soon as it granulates (and it granulates readily) it will sell for only a little over half its former price.

Chunk or bulk comb honey will granulate much more readily than honey in sections. In a like manner extracted honey will granulate more readily because of the disturbance to which it is subjected in taking it from the comb. But clear extracted honey, when it granulates, is not injured.

Ontario Association Collecting Crop Reports

As usual, Mr. Morley Pettit, the secretary of the Ontario Beekeepers' Association, is sending out requests for crop reports in the form of return postal cards, one side addressed to the beekeeper, and having on the back the following to be filled out:

HONEY-CROP REPORT TO BE MAILED NOT LATER THAN
SATURDAY, JULY 31.

How many colonies, spring count: 1914 1915
Total crop of white extracted honey
Total crop of white comb honey
What prices have you received?
Name County
Address Township
Date Con Lot

Be sure to report for 1914 as well as for 1915.
When exact amounts not known, estimate as closely as possible. Poor crops or failures should always be reported, to keep the average right.

A system of accurate crop reporting is of inestimable value in a locality. What greater service can a local organization of beekeepers perform for its members than that of determining what the crop is and what prices are being secured?

The Editor of the Western Honey Bee Gets Some Honey

It will be remembered (see page 304 April 15, and also page 393 of our May 15th issue) we referred to our interview with the editor of the *Western Honey Bee* at his home a few months ago. We wrote him some little time ago, making some inquiries along honey-crop conditions and other matters. Apologizing for delay in replying to our letter he writes:

Mrs. B. and I, entirely without help, have (managed) 381 colonies of bees (spring count); increased by natural swarming to over 500; taken off, eased, and sold over 500 cases of comb honey,

and a ton of extracted; treated about 40 cases of black brood and half a dozen of American; introduced over 50 young queens, and, not least important, kept the *Honey Bee* toddling along on its somewhat wobbly legs, all since I saw you last.

Thanks for all the nice things you said about us. More biscuit and honey awaits your next visit.

We congratulate Editor Bixby on his success this year, notwithstanding the conditions seemed to be against him earlier in the season. While the crop of comb and extracted honey was not large, it was a great deal better than he expected, and especially for making increase from 381 to 500 colonies. But it will be remembered that Mr. Bixby was an old beekeeper in New York for many years. He then went to California and now seems to be no inconsiderable part of the honey-producing interests of that great state.

Referring to those biscuits and honey, it is almost worth a trip to California to bump up against Mr. Bixby's enthusiasm, and enjoy the hospitality of him and his better half. Those biscuits! Words do not describe them, especially when they are flavored with Bixby's honey.

If he or she is flooded with a lot of visitors who wish to sample those biscuits Mrs. B. will either have to decline with thanks or charge it all up to the editor of GLEANINGS.

Complaints against Certain Advertisers; when Patience Ceases to be a Virtue

It is expected in the ordinary course of business that some little misunderstandings will occur between the advertiser and his customer; but all of these can be and usually are adjusted amicably. The chief complaint we have is where the advertiser of bees or queens announces that he has stock on hand ready for prompt delivery, but yet fails to deliver till some time after the order is received. In many and most cases, if the customer wants a queen he wants her at once. The delay may mean the loss of a whole colony. Sometimes the stock is very inferior—much below the advertised specifications. Again, the advertiser may fill the order promptly, but if the queen dies, fail to replace.

To receive a man's money and hold it for a month, and then deliver a queen, or several of them, is not doing business on the square. While we are not anxious to get mixed up in petty quarrels, squabbles, or controversies, we feel a certain moral responsibility in getting differences adjusted.

We may find it necessary to do a little free advertising—that is, if some people do not do better. In other words, we will publish the plain unvarnished fact or facts which will speak for themselves.

We have certain advertisers who have been with us for years and years, against whom we do not know that we have ever had any complaint; but there are certain other advertisers whose records are not altogether satisfactory. If any of our readers have not been treated fairly by any of them we shall be glad to do what we can to get a reasonable adjustment; and failing in that we may have to give somebody some free advertising. It is not fair that those who do a clean nice business year after year should be compelled to compete against irresponsible people who do not give satisfaction.

Honey-crop Conditions; Prospects for Clover Honey Improved

THE United States weather maps and reports from all over the northern clover belt show that there have been frequent rains every few days since the fore part of July, warm and hot spells following these rains, during which the bees did some work in gathering clover and basswood honey as well as sweet clover. These frequent rains have stimulated the growth of clover amazingly in the more northern states, so that even at this writing it is still in bloom and will continue up to the 15th of this month, or even clear up into September. In all of our thirty odd years in connection with this journal, we do not remember a time when white clover and alsike stayed in blossom as long as they have done this year, especially with a prospect that they will remain so in many localities the rest of this month.

Our subscribers have been very liberal in sending in reports, and we have received a larger number since our last issue than at any time in the season. These all go to show that the prospects for clover honey have materially improved. While it would be unwise to make a positive prediction at this time, there are many indications to show that this will be a far better clover year than last year, and it may even rank as one of the good years. The conditions this season have been more favorable for the production of *extracted* than of *comb* honey, because the flow has been slow; but there may be a big yield of clover extracted. But of one thing we are sure—there is from a light to a fair crop already in sight.

Reports with one or two exceptions show that basswoods have yielded well where any

are left. Sweet clover is more abundant this year than for several years back. The frequent rains have given it a big boost; and some of the white-clover honey will have a slight flavoring of sweet clover. A little of this honey in clover always improves its flavor; and those who have a combination of the two will probably secure fair prices.

Most of the white-clover honey will come from the following states: Northern Ohio; parts of Pennsylvania; Vermont, Michigan, Wisconsin, Minnesota, Illinois, Iowa, Missouri, and Kansas. In all of these states there will be spots where there will be no honey. Most of the poor reports are from the southern states. In Delaware, Maryland, and New Jersey, as well of a larger part of the New England states, there will be an almost complete failure of honey. The same is true of most of the southern states south of the Ohio River. Reports are unfavorable from Oklahoma, south Texas, and parts of Oregon and Washington. In the two last-named states there have been too many cold rains and too much chilly weather.

In Texas it has been the reverse—too dry and hot.

California seems to be coming ahead much better than the early reports indicated; but still it cannot be claimed that the aggregate yield has been up to the expectation of its beekeepers. Some have secured good crops; but the great majority have only from poor to fair yields. But enough has been secured so that already a couple of earloads of sage has gone east. This will be shortly followed by alfalfa from the Rocky Mountain states. If the yield from eastern clover should prove to be large it would make a slight slump in the price of alfalfa and California sage extracted. But of this no definite statement can be made—probably not before our next issue or even till the first of September.

Prospects for buckwheat honey are very good in those sections of the country where it is grown—particularly in New York.

For some reason we have almost no reports from Canada. Whether this indicates a failure of honey or not we do not know; but as the conditions have so materially improved in New York, northern Michigan, and Wisconsin, we should naturally assume that the same atmospheric conditions would favor at least a light crop in Ontario, Canada.

Reports are not numerous from the Rocky Mountain districts in regard to the probable yield of alfalfa honey. But there seems to be a sort of under-current of feeling that there will be nearly if not quite the same yield that there has been formerly. As

a general proposition the irrigated regions of the Rocky Mountain states are more sure of a crop than almost any other part of the United States.

PRICES.

At the present writing it would appear that prices on first quality No. 1 and fancy *comb* honey will be firm. Whether they will hold up to last season or not we cannot say. Prices on clover and alfalfa extracted, of best quality, will probably be a little easier than last year, although unfavorable weather during the rest of this month in the clover districts might give them an upward trend.

Reports from most of the states south of the Ohio River have been decidedly unfavorable. The cold backward rainy weather in June and the fore part of July prevented the bees from getting any honey; and when the weather warmed up it seemed to be too late for the clovers to do much good. Most of the reports from the northern clover states, if we except the New England states, and Delaware and New Jersey, are good—very good. Most of the poor reports come from the southern states south of the Ohio River, going as far west as Texas.

Prices on southern honey on account of the general failure in the south ought to be firmer than last year. They cannot be weaker, that is sure.

How to Get a Cheap Automobile Truck for Beeyard Work

WE have been using, for two years back, a regulation automobile truck with our out-yard work. It has a capacity of 1500 lbs. weight and at a speed of from ten to twenty miles. At the maximum speed the engine has to go at a terrific rate; so the speed in practice is not much over fifteen miles an hour. This however, is three times as fast as a team can go.

This year we rigged up one of our old five-passenger automobiles (an Overland), 35 horse power, which has been used for five or six years. Last winter the engine and the running-gear work were overhauled, the body removed, and a regular wagon-box or truck-box was substituted, at a small cost. In our general beeyard work it was our intention to use this built-over fast-speed truck in preference to our regular automobile truck of slow speed. As a matter of fact, the former is oftener used; while the touring-car truck will not carry more than half the load, it goes so much faster and easier that we have found it more profitable to use. It is seldom that we desire to carry more than 700 lbs. weight; and the fact that it has an

economic speed of from 25 to 30 miles an hour makes the distance between beeyards comparatively short. The larger tires, the larger wheels, and better springs, enable the boys to go more in comfort, and with less shock and jar on the combs, when bees are removed to an outyard. We found, also, that 700 to 800 lbs. is about all that we desire to carry at a time. By doing a little head work we can plan to carry a good many tons of freight in a season. We are always carrying something. When we get into the extracting season, one big extractor with a complete outfit can be put into this fast truck, thus saving the expense of an extracting-outfit at each yard.

Good second-hand five-passenger automobiles can now be purchased at from \$150 to \$200, and \$50 ought to supply such a machine with a truck body with high sides. Never buy a second-hand automobile without getting the advice of a disinterested expert. A good machine should not cost to exceed \$250; and a second-hand automobile truck would cost twice that, nor would it begin to be as serviceable. Fast speed and comparatively light loads are more practical than a slower speed and heavy loads for ordinary outyard work. At other times the touring body can be substituted for the truck body and the whole family take a ride.

For a picture of our converted touring-car automobile truck see Fig. 4, page 590, of our last issue.

Going too Far with Live-bee Demonstrations

WE have just received a newspaper clipping relating an incident where a beekeeper has been giving live-bee demonstrations; and was severely stung. It seems he had been advertising that he would "take a bath in live bees." He stripped himself to the waist and poured the bees into a pan and then poured them over his bare back and chest. There is nothing so very awful about that kind of work if it is properly done. But the average person makes a bungle of it. In the first place, he should take only gentle bees, and in the second place he should not use the same bees more than once; and in the third place he had better not strip himself to the waist. Bare arms, head, and neck "will astonish the natives" just as well as the bare back and chest; and the danger of being seriously stung is not nearly so great.

It appears that our operator referred to in the clipping was so badly stung on the bare back on one of these occasions that the

doctors had to work over him half the night before he could be relieved. Then, according to the newspaper report, he proposed to go right into another demonstration the next day.

We cannot too strongly condemn such foolishness. While there are lion-tamers who can stick their head in a lion's mouth, too many have their heads crushed to make the practice safe.

We have given some two hundred live-bee demonstrations, and with one exception we have never been stung more than two or three times all told. The exception referred to was where we were foolish enough to borrow another man's hat. The hat proved to be an old one, literally soaked with sweat and dirt; and when the bees were dumped into it they immediately showed their aversion by boiling over; and when the hat was placed on our head the bees stung us, not once but several times. Of course we removed the hat and gently combed the bees off from our head as though nothing had happened, and went on with the lecture, and no one was the wiser; but next time we made up our mind that we would use our own hat.

There is no need of one being stung at such demonstrations providing he does the thing properly; and a live-bee demonstration will draw a crowd for the purpose of selling honey as will nothing else.

We take a gentle strain of bees and shake them into a tin dishpan. Then we roll them over a couple of times. We next gently run the hand into the mass of bees, taking care not to pinch a single bee. The movement must be very deliberate. It takes about a full minute to pick up a handful of bees. To push or crowd the bees too fast will cause them to sting. A common dishpan that is slightly greasy is better than anything else. The bees cannot stick to it, and it is our usual plan to roll the bees into one hand. There is no danger of being stung if one is careful not to pinch the bees. With the handful of bees we walk down into the midst of the audience, and explain why they do not sting. Following this we shake the handful into our own hat, then place the same on the head, and continue the lecture. We have sometimes put a few bees in the mouth and blown them out. While we have never been stung more than once, we consider this an unnecessary demonstration.

A couple of years ago, for the benefit of the moving-picture men, two of our men offered to strip to the waist. We then took a large panful of bees and poured them over the backs of the boys. In the mean

time the camera man was catching the whole performance. But a couple of the boys were stung, but not bad enough to cause any trouble—two stings in all being the number received.

The average beeman should be warned against this kind of performance. Where one is immune to stings and understands the job, there is not much danger; but look out for the first time.

Temper of a Colony of Bees Dependent on Locality and Environment as well as Weather Conditions

DID you ever notice that bees in an open yard, without shade or shrubbery, are apt to be crosser, almost invariably, than the same bees or the same strain of bees located in a grove, orchard, or in any position where there is low shrubbery sufficiently high to screen one hive from the other? When the Texas shipment of bees arrived at Medina we placed them partly in the home yard with its grapevine trellises, and partly in our outyards, most of which have no shade. It was very noticeable that the Texas bees were much crosser at the outyards where every hive is exposed to plain view than the same bees (or strain of bees rather) at the home yard screened by the grapevine trellises. These vines were anywhere from five to seven feet high, and about four feet wide, and they stand immediately back of or on the south side of the hive. If the operator happens to strike a cross colony, the bees that have offered attack soon lose track of him because he is screened by vines out of their sight when working the other hives. On the other hand, if the operator happens to stir up the bees at an outyard where the view is unobstructed at every hive, those same bees will follow him about until he finishes his work at the yard. They will attract other bees, with the result that he will receive more stings than he will from the same strain of bees at the home yard that lose sight of the operator as soon as the hive is closed.

Our grapevine-trellis apiary affords a screen and protection to our boys in a way that we do not have at the outyards; and even when those outyards are in groves or orchards, the bees are not quite as easily handled as those in the home yard where every hive is screened behind a trellis of grapevines.

At the ordinary yard it is practically impossible to find a better spot to afford protection than these yards screened by low shrubbery or by an orchard. In locating

yards it is better to place the entrances as far as possible from a cultivated field. A span of horses switching their tails may obstruct the flight of the bees, thus causing trouble; so we are obliged at times to select an open spot of ground where every hive is visible from every other hive. The ideal location for any yard is a spot not near the general highway, remote from cultivated fields, with individual screens for each hive in the form of vines or low shrubbery which will cast its leaves during the cold part of the year, so that the warm rays of sunshine will be available when they are most needed, and become shut off during the middle hours of the day in hot weather when they are a detriment.

Permit me to add that Ernest submitted the above to me before it was put in type, knowing what I had in mind when I planned a hexagonal apiary with a grapevine for shade on a small trellis for each hive, something like forty years ago. At the same time, I experimented with different kinds of grapevines, and found the Concord less trouble to train as I wanted it than any other variety. Most other vines require too much pruning and clipping to keep them within bounds. It is gratifying to know that my convictions at the time have been "proved out."—A. I. R.

Why Bees Work on One Species of Flower at a Time, and Neglect all Others; an Interesting Study

On page 519 of our July 1st issue we spoke of that big field of yellow sweet clover near the home apiary. We went over to see it a great many times. The low and contented hum of the bees, thousands and thousands of them as they went through the blossoms, was something worth seeing and hearing. But all through that sweet clover there was alsike, for both were sown together.

We noticed that the bees that worked on yellow sweet clover paid no attention to the alsike. This same fondness for the same species of blossoms has been noticed in all the bee-journals for years back; but long, long before the observation was made in the bee-papers, Darwin, following Aristotle, had called attention to the same remarkable specializing on the part of the bees.

One day we spent nearly an hour to see if we could detect a single bee that would go from sweet clover to alsike or from alsike to sweet clover; but not once did we notice a single case.

Admitting that the bees do specialize (and there can be no question on this point), why do they do it? The suggestion has been made that a young bee, when it goes out into the fields, gets into the habit of going to a single species, and it keeps up that habit so long as that species gives up its treasure. But why should it not take a sip here out of one blossom and a sip from another entirely different species, and thus have a little variety of flavors? The suggestion that one bee finds it more convenient to work a single plant and another for another because they learn how at the beginning, does not altogether satisfy us. Is it not more than likely that the great Creator might plant an instinct that works to the advantage of the insect as well as to the vegetable world? The very fact that one bee gathers only one kind of pollen or nectar on a trip makes it possible for that bee to bring about better pollination among those particular plants than if it worked hit or miss among a dozen different flowers that might be in bloom. Mixed pollen from different species would not pollinate a particular species. For instance, apple-trees, while of all one species are of different varieties. In order to get good crops, fruit-growers know that they must mix the varieties. The same is also true of pears, peaches, and a great variety of stone fruit. The pear-growers know that it is not good practice to put the Bartletts all by themselves, the Seckels by themselves, and the other varieties by themselves. There must be one row in alternation with another in order to get the best results. The same is true of apples and other fruits. The busy bee comes in, and goes from one variety to another, bringing about cross-pollination; but bear in mind these apples all belong to the same species. The very fact that the bees follow that habit of working on only one species at a time renders it possible for them to carry only one kind of pollen at a time, thus bringing about a better pollination than if they carried a mixed pollen.

It cannot be argued that the bee has in mind the production of a big apple crop for the benefit of the fruit-grower. Nay, rather, it is concerned only with its own need of supplying nitrogenous food to its young. Would it not seem then that the allwise Creator had implanted an instinct by which the bee, for a reason of its own, which we cannot discover, would do the very thing that would help out the plant world at the same time?

We find all through nature a beautiful harmony. Sometimes man disturbs that

harmony, with the result that disaster follows. Certain plants, by a display of color, nectar, pollen, or all three together, invite the attention of certain moths and butterflies. Others seem to attract the diptera, or certain flies, while the blossoms of edible fruits and certain grains seem to be especially adapted for supplying bees with a food that they must have.

Some, perhaps, may doubt whether there is an "understanding" between the animal and vegetable kingdoms, or, to be more specific, between the bees and the fruit-trees, yet how else can we explain this beautiful adaptation unless the allwise Creator has brought this about in order that his great creation, man, might enjoy the product of the hive as well as that of the apple-tree?

There is a beautiful adaptation between bird life and plant life. Destroy the birds, and our useful plants and trees would perish from the attacks of injurious insects. Without food for man, he would soon become an extinct species along with all other forms of life. If we go into certain localities we see certain birds and certain plants and certain animals all work together in harmony.

On one of our western trips we asked why the ranchers did not kill off all the coyotes. They said it was for the simple reason that the coyotes kept down the jack rabbits, and the rabbits would be a pest unless there were something to hold them in check. If the small boy with his toy gun were allowed to shoot birds indiscriminately we should soon be overrun with certain insect pests.

If we reverse the rule we find that if we try to grow more fruit than the natural bees in the woods can take care of, much of the fruit will not mature. A few years ago when cranberries were grown in the Cape Cod region (about ten or twenty acres), it was discovered that the big plots would not yield in proportion as the small ones did. When bees were imported into that locality—enough so that the balance of Nature was restored—they could grow as many cranberries per acre in a ten-acre patch as they formerly could on a half-acre.

Perhaps this may seem like a long diversion from our original theme; but it only goes to show that the allwise Creator has brought about a working balance; and in order to keep up that working balance bees have been taught to specialize in endless ages until the instinct has been so thoroughly implanted that it is compelled to bring about perfect pollination that could not be accomplished indiscriminately in their quest of food for their young.

STRAY STRAWS

Marengo, Ill.

MY BEES were on the verge of starving in June: clover plenty a-bloom, but too cold for flight, and I fed much as described on p. 522, only I used sugar syrup and poured it on top of the sections.

H. P. KIRBY writes that for bee-hunting purposes he uses vinegar instead of water to dilute honey because it attracts bees more strongly. He also says that vinegar added to sugar syrup greatly increases its attractiveness, which may sometimes be quite an item.

B. F. AVERILL speaks of bees gnawing basswood splints, p. 538. If given when bees are storing, and the bees build comb over them, I have never known them to be gnawed afterward. If they are given when there is no storing or building, the bees are likely to gnaw them, and, what is very much worse, the foundation is badly gnawed.

MORE AND MORE I am learning that I mustn't set down my experience as the experience of every one. The Byer-Chadwick discussion brings up another point of difference. When friend Chadwick's bees go queenless in spring he expects laying workers. I've had many a case of laying workers, but I don't remember a single case in spring. By the way, friend Chadwick, you say, p. 525, "as a last resort, a worker is chosen to perform the functions of a queen." Did you ever know a case of a laying worker and not a whole lot of 'em?

J. L. BYER says, p. 440, he has heard queens quahk in a box in the postoffice. First time I ever heard of a queen quahking outside a cell. But I know no reason why she shouldn't. Some have said quahking is the same as piping, only muffled because in a cell. But the length of time of the notes is entirely different. [If you were in an office where four or five dozen queens were lying on a desk preparatory to being sent out in the mails you would hear a good deal of piping. We have heard them answer back and forth time and time again.—Ed.]

A. I. ROOR, last year you sent me dasheens so late they made little growth. I wintered them in the cellar in the same box with *Caladium esculentum*, or elephant's ear. I planted all this spring, and they didn't come up till July 1, and I can't tell by their looks whether to admire their beauty or to eat 'em. Fact is, except for size I don't see but dasheens are just as pretty as caladiums. From the name, "esculentum," one would expect the caladium to be edible.

But I've tasted it raw, and it bites like an Indian turnip. Cooking might correct it.

C. H. CARGO, I've studied no little over your letter, p. 518, and wondered whether you mean just what you say. You want "a healthy sentiment created that refuses to allow any party to try to monopolize our voters, but insists on every party," etc. To my certain knowledge there's been a healthy (?) sentiment of that kind for 40 years; our forces have been scattered, and the devil has chuckled over it. If we wait until every party has a prohibition plank in its platform, we'll wait some time. Don't you believe if we had all got together in some one party we might have finished up the saloon before this? [The principle is all right; but the trouble is, there has been a condition and not a theory, and that condition has been that the great majority of the voters would not desert their old party. Whether they will in the future remains to be seen. In the meantime, regardless of parties, the temperance question from an economic standpoint is moving forward by leaps and bounds. Insurance companies, manufacturers, bankers, railroad companies, business men, city property, country towns and country districts, are finding out from a financial point of view that they cannot afford to tolerate the saloon. Indications at present go to show that financial considerations plus moral and religious reasons will oust the saloon in the near future. "Safety first," and the cost of damage suits as the result of unsteady brains or brains crazed by liquor, are having a tremendous effect on the big corporations of the country. Moderate drinkers are not wanted, and regular drunks are nuisances. The labor unions are beginning to join against the common enemy. Banks that formerly bought brewery stocks as a good investment are discovering that they are the poorest kind of security; while many of them have stood with the wet crowd because of their holdings, they are now dumping those holdings because they are not worth the paper they are printed on. Great breweries are going into the hands of receivers. Saloons are voluntarily going out of business because they don't pay. Revenue receipts fell off more than seven million dollars in the Peoria district the past year because of the movement toward the elimination of whiskey from the life of America. Peoria is the greatest distillery city in the country. The mighty wave of public sentiment is getting in its work. State after state has been going dry.—Ed.]

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

Does anybody know a better way to celebrate a holiday than picnicking out in the hills, visiting a beeman or two on the way? It was by far the best thing we could think of to do on the Glorious Fourth. There were four of us, the other two also with bee sympathies, one to the extent of five colonies as a nest egg down in Alabama. The day (Monday, the 5th) was perfect, the country fresh and beautiful from recent rains. Out in the hills, to be reached only by a delightful drive, we came to one apiary of one hundred and twenty odd colonies, the strongest-looking colonies I ever saw. But the crop was as dismal as our own, only on a larger scale—practically a failure; viewed in the light of expectations, a distinct failure. After watching the bees and talking shop awhile, we drove back out of the hills to the pike again, and turned off to the river. There we were ferried across stream, and headed according to the ferryman's directions toward another bee-yard. The road ran along the river, between a tangle of growth that brushed our faces on the right, and an apparently interminable field of corn on the left. Neither one seemed to have an end; and as it was getting late, and we were all developing a prodigious interest in the generous lunch-basket and the freezer of peach ice cream, and were reminding one another of the ferryman's ominous remark that we had better be back by sundown if we wanted to get back to our own side, we gave up and turned back. Whatever that farm may or may not yield as to a honey-crop, there are four of us prepared to testify to the excellent corn prospects.

Unfortunately, this honey-crop failure seems uniformly true of the immediate Nashville vicinity. The winter stayed too long, the bees built up too late, the clover

came too early, the rains came too late, there was too much bad weather during the clover bloom.

And perhaps there wasn't much nectar in the clover blossoms anyway. Of that I'm not quite sure. Anyway, the most of what little honey there is seems to be locust. And there are many disappointed beekeepers. One man says he will not sell enough honey to pay for the supplies purchased last winter. "Bees haven't done a thing," others say. Our own crop is practically nothing; and as we have been making some nuclei, we expect to be feeding soon, which, indeed,

is likely to be the lot of many of us here. I hope this disastrous shortage may be quite local. Some parts of the state, our inspector reports, show very fair results.

* * *

I not only agree with Mr. Doolittle page 486, about saving bee-journals, but I would especially emphasize the thought of reading them thoroughly before you save them. Read them thoroughly, and, unless you object, mark them too. At the end of the year you will get an index; but you may want to refer to them many times before that. Read with a pencil in your hand, and you can check the things you care especially for. Then make an abbreviated notation on the white margin of the cover, and then how easily you can find things! Glancing at random through our 1915

copies of GLEANINGS, I find one copy marked 242, inc (increase); 236-7, f. b. (foul brood); 249 bnd'g jrnls (binding journals). Some of them, evidently marked hurriedly, show merely page numbers, as 291, 307, 381, 397, etc., while on the pages themselves are checkmarks calling attention to the paragraphs of articles of particular interest. The July 1st cover says, "Doolittle on Honey-getting, page 259." None of us are in danger of knowing too much, and constant study is surely well worth the effort.

SONG OF THE YOUNG QUEEN-BEE.

Out of the warm, close, waxen cell
I have come, I have come!
Out of mysterious silence and growth
Straight into life I have sprung!
And the far, dim past of my ancient race
Leaps in my blood, and I know my place
In the midst of the motion and hum.
All these, they are thousands, and I am but one—
I am queen—queen!
Vivid and slender, with gossamer wings
Woven of shimmer and sheen.
And something within me, with urging and thrill.
Makes me a-quiver my fate to fulfill.
I am queen, queen, queen!
Not you, royal sisters, astir in your cells,
But I—I!
Who willed it? I know not; but this thing I know—
I shall live, you must die!
You too are slim-bodied with cobwebby wings,
But passionate life surges through me and sings,
"It is I, I, I!"

BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado.

CROP CONDITIONS

In the Rocky Mountain region, honey-crop conditions are still up in the air, so to speak. In Idaho many discouraging reports have been received. Wind has interfered with the flow in the Idaho Falls district, and feeding was done until the first of July, and in some places probably later.

Cold, cloudy, and rainy weather in the Twin Falls district kept the bees from taking advantage of the first crop of alfalfa. Bees went backward in May and early June, but feeding was not necessary as late as in some districts. Prospects are good now (July 10), and early July saw many colonies building queen-cells, and most colonies will doubtless make some surplus honey.

Reports from Utah are discouraging in the extreme on account of the ravages of the alfalfa weevil.

Mesa County, Colorado, has had no flow from first alfalfa, and grasshoppers are reported very bad, with prospects poor.

Garfield County reports a good flow early in July, and fair prospects.

Delta County conditions are fair to good with indications that some new comb honey will be taken off by the middle of July.

Conditions are backward in Montrose County, with nothing favorable to report.

In the Arkansas Valley new honey is reported being stored in the hives in and about Canon City and in the Ordway district. From Rocky Ford to Los Animas conditions are very much behind what they should be, and little new honey showing.

In the lower Arkansas Valley things are a little better, bees having stored some honey from first crop of alfalfa, only to go backward early in July; but to-day, July 10, things seem to be picking up, and some colonies are beginning work in the comb-honey supers and extracting-chambers.

Swarming has begun in the southwestern part of Colorado, and prospects for a surplus crop are fair.

In northern Colorado prospects are the poorest of any place in the state. This condition is largely caused by the fact that the bees are not ready for the honey-flow, or very few of them are. In large areas there was a dearth of pollen and also a lack of stores. Many beekeepers did not feed sufficiently; and where pollen was scarce it did little good.

If Boulder County has half a crop of honey I shall be agreeably surprised. Many

colonies have gone backward until they are little more than nuclei.

Sweet clover looks fine; and with good weather appearances might change, and a fair crop be harvested; but a nucleus in July cannot be counted on for surplus.

To sum up, a few restricted districts will have a crop of honey this year; but a general good yield is past hoping for.

NON-SEPARATED OR SEPARATED HONEY.

Mr. Latham, page 530, July 1, says that, after weighing thousands of sections of both separated and non-separated honey, there is no more variation in weight in one than in the other. Did Mr. Latham weigh his own honey, or was it the honey of the average beekeeper? I will controvert the statement if he will apply it to the average producer of marketable comb honey.

I have seen sections of non-separated honey, practically all sealed, weighing not more than eight ounces. I have not seen any separated honey as light as this. I have seen non-separated honey, completely sealed, weighing 21 ounces; and I have never seen a separated section of honey weighing over 17 ounces. I have in mind the $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{7}{8}$ two-beeway section.

If as good results can be secured as Mr. Latham says he gets, there is ground for the belief that some commercial honey-producers would profit by discarding separators; but it will require closer attention to super work than most honey-producers give; and the extra time taken would doubtless offset the advantages.

I agree with Mr. Latham that all comb honey should be cartoned; but why does he refer to the bottomless-topless carton when you are supposed to slip the section in from the side, and the two-beeway section then practically seals the package? It is, of course, not as closely sealed as the regular carton.

I think the argument that the flat surface of separated honey tends to strengthen the idea that comb honey is manufactured is a poor one. I have never heard it. The most damaging idea the public gets is the comb foundation used by beekeepers, which many people think is manufactured comb, and the fact that often beekeepers buy large quantities of sugar to feed the bees. Added to this, the granulation of honey has its effect on the public. These are our obstacles.

Take the product of fifteen beekeepers who use separators and fifteen who do not, and pack both lots and size up results.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

It seems that our eastern brothers have been getting a taste of the same variety of weather that reduced our orange flow at least 75 per cent.

* * *

Spreading brood is rarely necessary where a young queen is at the head of the colony. Their first operations will extend the brood-nest just about as fast as their bee force will permit. Even the fault of the bees blocking the way with pollen is greatly reduced with a young queen. Some way they seem to get matters to move along much better than with an old queen.

* * *

The value of wired combs was most forcibly illustrated to me recently when four colonies that were being moved on an auto truck fell with a thud. Aside from slight damage done to few combs, and the crushing of a few bees, the accident was not serious. With unwired combs the whole lot would have been a mass of broken combs and dead bees, making the loss almost complete.

* * *

My queen-rearing this season has been carried on by Mr. Byron Crawford, who was with me last season and part of the previous one. He has become interested with me in the bee business on general lines, and I hope he will remain with me for many years to come. While he has been out of his teens only a few years, he has a store of knowledge on bees of which any young man of his age might well be proud.

* * *

Judging from scattering reports from various localities in the southern end of the state, there will be no very large crop of honey in the sage districts this year. Had this been the year for a sage flow we would have seen the largest crop of sage honey in recent years. Some are inclined to the belief that they have a sage crop this year; but the fact remains that they secured only a comparatively small amount, considering the immense rain, and late rain at that.

* * *

The value of young queens, and what they can accomplish, has been more thoroughly proved to me than ever during the last few weeks. Requeening was begun with colonies that were not requeened last season, and that failed to come up to standard. With vigorous young queens these colonies have forged to the front, while colonies with

last season's queens were slowing down in their brood-rearing operations and decreasing in numbers. The fact most significant to me was that where a vigorous young queen began operations, even the worst honey-bound brood-chambers were cleared for her, and the honey moved above the excluder.

* * *

We have had some perplexing experiences during our operations of requeening. Many cells have been lost by being torn down in mating-hives. If a protector was used then the queens would be balled for a few days, or even after returning from the mating-flight. Colonies hopelessly queenless have killed as many as three laying queens. The only plan of introduction that has a score of 100 per cent safe was by the method recommended by Mr. Doolittle. But just to prove that new conditions are met from time to time, and that the bees are sometimes on their good behavior in spite of all precedents, I will state that only a few days ago Mr. Crawford and myself discovered two young queens less than a month old laying in the same brood-chamber. We have placed one above an excluder over the other, and will see if they will remain so during the winter, or whether one will eventually disappear, as is so often the case where two are left in the same hive during the winter.

* * *

Late in May I purchased twenty-three colonies of bees at what might be considered a very low figure. A few were in frame hives. Nearly all the frames were not wired, and in a part the bees had taken the liberty to build the combs crosswise of the frames. Most of them were in any kind of old box that happened to be at hand when the swarm was captured, ranging in size from a small soap-box to an orange-box. Twenty dollars was the price paid for this conglomeration. Hives were brought from the Tremont apiary with full sets of combs and an excluder. The bees from a box were smoked and jarred out of the box on to a set of frames. As soon as the queen was down, an excluder was placed over the hive and the box placed over the excluder. In three weeks the brood had all hatched from the boxes and they were removed, thus making a complete transfer without the loss of any time in the operation. If we had followed the old method of transferring combs to the frames the price would have been excessive.

NOTES FROM CANADA

J. L. Byer, Markham, Ontario

I am glad to see that recommendation of Carniolans, on page 520. Although I have given them up pretty well, owing to a European-foul-brood scare, yet I still really believe a good strain of Carniolans to be the very best bee, all things considered. The swarming propensity is overestimated in most cases, and we never had any trouble to speak of, but, of course, we used large hives.

F. C. Greiner's article on page 549 in the matter of foul brood and the effect it has on the industry of beekeeping is interesting and instructive. But I cannot refrain from making a kick because he does not label the brand he has been dealing with. This is a common error; and, while excusable on the part of a beginner, it is hardly so in the case of Mr. Greiner. Many of us will know at once on reading the article that he is referring to European or black brood, but others will not think of that, and perhaps try the plans given with our old friend American foul brood. The point is that, while the treatment he recommends is no doubt up to date for the disease he has in mind, for American foul brood it would be worse than useless. This criticism is made in all kindness; and in mentioning this particular article it is simply to emphasize the fact that a lot of similar mistakes are being made all the time, to the confusion of many who are not posted on the two diseases which are so radically different and require such different treatment.

As predicted in last batch of "Notes" for this department, the clover flow here in York County has been very light. Absence of showers early enough, and too much cool weather, is responsible. While we had abundant rain during last week, at this date clover is about over and the surplus is very light. Bees here in many cases were in poor condition for what flow we had, as the very bad weather that lasted all through May and much of June caused a heavy loss of field bees; and when clover came on we had hives filled with brood and baby bees, but a lack of fielders.

Basswood never looked better, but we have little. In localities where there are lots of trees there should be a good chance of

some nectar from that source. This is written July 7, and the bloom on basswood will not be open for a week. At our north location chances are yet good for a crop from clover, as it is later there and much more abundant. Basswood buds up there which gave a great showing were all frozen in the late June freeze. Buckwheat in York County is a heavy acreage as compared to other years, and much is sown early, which will give a long time of blossoming. Some of it is so early that if, by chance, we should get a basswood flow the two will likely go together.

Having mentioned the large yard we have up north at various times, some seem to think that these far-north locations are a sort of paradise for beekeepers. This opinion is gleaned from considerable correspondence that has come to me lately. Northern Ontario has lots of room for beekeepers, and in some seasons the country gives good returns from the bees—no question about that. But it is well to remember that, the further north one goes, extremes of temperatures, especially in regard to late spring and early fall frosts, are far more apt to cause damage than in more southern localities. Our north yard is only 100 miles from Toronto, and yet the difference in these matters is considerable as compared to our home apiaries not far from this city. For instance, the frost of May 26, already mentioned, did little damage to honey-producing sources at home, while up at the north yard, where we had a splendid showing for basswood, all the buds were frozen from the trees.

Then, again, there seems to be some confusion on the part of some as to the location where we have our bees; and it is well to remember that Ontario is a big province, and our bees are not in the northern part at all, strictly speaking. While our apiary is but 100 miles from Toronto, the great clay belt now being settled is over 300 miles north of Toronto at the south side of the tract running nearly as much more north and hundreds of miles west. Up there, clover, willow-herb, and raspberries are the main sources of honey; and while there is generally lots of honey flora for the bees, as before intimated, weather conditions are more uncertain one year with another the further north one goes.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

NEW QUEENS IN THE ANNEX

"When a hive is so full of bees that the bees begin to think about clustering out, they will crowd into an empty space which may be about the hive, much sooner than they will go on the outside for the same purpose. Suppose that as soon as the sections are filled with bees, and before the swarming fever comes on them, we bore a three-inch hole in one side of the hive, and on the inside put a piece of queen-excluding metal. Bore a similar hole in an empty hive; cover it with queen-excluding metal, and set this empty hive right up against the other having the bees in it, so that the holes match. Then put a queen-cell in this empty hive. Now the point I wish to know is, will there not in time be a new swarm of bees in that empty hive?"

I doubt whether this will work just as you have outlined it; but there may be something in it, if the plan is modified. From past experience I am convinced that, if the bees did go into the empty hive on the return of the queen after mating she would enter the wrong hive, and in all probability be killed or balled by the bees until crippled and spoiled for usefulness, even if she finally superseded the old queen.

But what is there to hinder putting one or two frames of brood and one of honey in the empty hive and then giving the queen-cell? I would not warrant the bees going freely from one hive to the other to care for that brood and queen-cell. If the young queen should consider the old queen in the parent hive her rival, so as to go to the excluding-metal and there challenge her to a combat, the bees would doubtless ball her till she was no good, or she would turn up missing, as is usually the case when such a combat is challenged.

Many claim that a queen emerging under such conditions will be cared for just the same as if she were in an isolated hive or nucleus, and in due time become fertile and go to filling the combs with eggs. From scores if not hundreds of attempts to work out the plans with dual queens in a hive, as given by the late Mr. Alexander and others, my experience has been that this cannot always be depended upon. In having queen-cells cared for and reared above and behind queen-excluding metal, I have had the best of success with the mother queen doing duty just the same as if her progeny were

not perfecting them by the score on the other side of a perforated metal. It is only when the young queens from these cells begin to assert their "queenhood" that the trouble seems to arise.

"Would not the plan as I have given prevent the original colony from swarming? If so, this will make unnecessary some one staying at home Sundays and other days to watch for swarms, besides proving a boon to those having out-apiaries which they wish to work for comb honey.

Well, as I said before, I do not think it would work just as you gave it, but by using the suggestion given, as I have explained, I see no reason why it should not stop swarming entirely. As soon as the young queen lays, or before the old colony is strong, take one or two more combs of brood from it and put in their places frames of empty comb or frames filled with comb foundation, so the bees will have no chance to build drone comb, quitting the brood thus taken out over into the hive having the young laying queen. As soon as the flowers from your main source for surplus honey open, the original colony should have the surplus arrangement put on, in which are "bait sections." The first honey will be put in the sections rather than the combs in either hive, thus making your prospect of success even greater than it could be otherwise. At the same time, sections should be placed over the part of the new hive where the brood and combs are, so that in no case the bees lack room to store all the honey there is coming in. I would have these sections in every case filled with foundation, so that the bees would have no desire to swarm by being loath to build comb.

Occasionally, or as often as the out-apiary is visited, move more frames of brood over to the new hive, putting frames filled with foundation in place of the frames taken out each time until the new hive is full, always putting on sections in the case of either hive, as the colonies seem to require. If the new colony is a little slow in taking advantage of the sections, give bait sections to this also, as the results will be enhanced by getting the bees at work in the sections at the earliest possible time as regards the honey-flow. When well at work in the sections, and in the early part of the flow, raise the first super and put another under it, to induce the filling of as many sections as possible.

GENERAL CORRESPONDENCE

BLOOM IN THE COLORADO FOOTHILLS

BY WESLEY FOSTER.

For three years I have followed the practice of moving my bees to the foothills for the spring bloom. Until this year it has yielded very satisfactory returns. In 1913 it was possible to double the number of colonies by June 15, and have all colonies ready for alfalfa and sweet clover in June,

prospects from the horsemint; but this plant is seemingly very susceptible to frost injury, and a large proportion of the plants were stunted or killed outright.

This year I have been taking a census of the wild flowers upon which the bees gather honey or pollen. First among the mountain bloom I place choke-cherries, then hawthorn [Cover picture.—Ed.] and thimbleberries.

A little later (in June) come the astragalus, penstemon, oreocarya virgata, the lupins, wild geranium, and numberless others that I will tell later.

Thimbleberry. A bee can be seen on the blossom in the center.

July, and August. This moving was and is expensive, as two moves are worse than a fire, they say; but when bees are concerned, it hardly works out so disastrously.

I have this spring moved in only 160 colonies; and while they have done well, the flow from white clover and dandelions has been good where my apiaries are permanently located, so that the value of moving has not been so very apparent. The late hard freezes in May and June destroyed the nectar-secreting powers of the flowers in large part. Early in the season we had fine

We had fine prospects from the horsemint.

The astragalus, if I have been informed correctly of its name, is very attractive to the bees. I have been calling it wild alfalfa, for the reason that the odor of the blossom resembles alfalfa bloom. The astragalus has a pea-shaped blossom, not so compactly placed as alfalfa bloom, but of somewhat the same color, though not so blue as alfalfa. The plant grows about eight inches in height, and probably comes first, or ranks first, along with the penstemon as a favorite with the bees. The penstemon is a blue and light-blue blossom growing on a stem about eighteen inches high. It is a beautiful plant, and I have seen five bees at once on a single stalk of blossoms. Wild geraniums are very well liked by the bees, and would be more important if there were more of them.

The lupins comprise many varieties, and are very numerous this spring. The bees are not found so thick upon them; but from the abundance of the plants I would judge that the nectar secured is not insignificant in the aggregate.

The odor of the astragalus resembles that of alfalfa bloom.

While the wild bloom is not our source of surplus, it is so very important in the spring that we cannot ignore it. Western beemen will do well to become familiar with the mountain and plain wild flora of the western states.

Boulder, Cal.

SOME ODDITIES IN NATURAL LAWS

BY EDWIN G. BALDWIN, A. M.

A few days ago, even before we were up, our attention was drawn to the south window of the bedroom at our home, where, through the open casement, was wafted to us the sound of humming bees. I arose to see the cause. On examination it was at once clear to me that the bees were busy on a flowering shrub that fills, even to the eaves, a corner of the house formed by a bay window projecting toward the south.

The busy little workers were swarming

over the plant, which is a jasmine (not a jessamine, for the two are distinct—*Jasminum officinale*, to be exact). It is half shrub, half climber, covered much of the late summer and fall with myriads of snow-white blossoms, each about half an inch in diameter at the outer edge of the petals. It is rather fragrant, though not nearly so fragrant as the star jessamine, with which it is sometimes confused.

Now, we knew that the petals of this

jasmine are too long and narrow for bees to reach the honey at the base of the corolla. Only butterflies, millers, humming-birds, etc., can reach the base of such deep petals. Consequently we had not thought that honeybees would be attracted to the flowers at all. Imagine if you can, therefore, our surprise on seeing the bees hovering about and working on, not the blossoms, but on the bases or stubs (calyx or ovary of the blossom) left after the petals had fallen off! The white petals fall very early, leaving the vine full of the green bases or stubs.

The *penstemon unilateralis*. Three bees are working.

in the bottoms of which we could distinctly see a tiny drop of nectar shining. It was for this nectar that the bees were visiting the shrub. They were tarrying lovingly over and dipping into the bases, not merely running over them, as they sometimes do when in quest merely of pollen. They were getting honey too, for their distended bodies showed that their visits were not in vain.

The interesting thing to me was this:

Wild geraniums are well liked by the bees.

Why does Nature allow an apparent miscarriage of her plans? for the petals in this jasmine form a star-shaped tube, which, when it falls, carries away with it also the stamens that adhere closely to the inside of the petals, and so carries the pollinating elements of the blossom. No good could, therefore, possibly result to the blossom from any visit of the bees after the petals were gone. The bees, we might almost say, were mere looters, taking what was left, but paying no toll of fertilization to the plant for the nectar obtained. The blossoms would have been fertilized equally well without the visitations of the bees. Why is it so? Is it some slip in nature, some abortive condition of a principle otherwise effective and efficient, world-wide in application?

Our wonder is increased when we reflect that this shrub is not the only instance of such abortion—if such it be—of a wide principle. The cotton and the partridge pea (sensitive pea, *Cassia chacmicrista*) of northern Florida and southern Georgia are both illustrations of a similar oddity. In these two plants it is not the blossoms that secrete the nectar, but small petiolar glands or leaves at the base of the blossoms. In a recent letter from Mr. John H. Lovell, of Waldoboro, Me., I was interested to note that he also finds some of the workings of nature's rules rather odd. He remarks of this trait in cotton and the par-

Lupins cover the brook bank. The blossoms are purplish red.

tridge pea. "The glands would appear likely to distract the attention of insects away from the flowers." That is, the presence of these nectar-secreting bracts, elsewhere than in the blossoms, would probably lessen the chances of insect-pollination rather than assist in the nuptials of these plants.

Who can fathom altogether the workings of even the simplest rule in nature? Who can explain to us the workings, the cause, and occasion for these apparent slips in the operations of the rule of insect-visitation

and plant-fertilization? Are they like the appendix in the human system, or the presence of nipples on all male animals—mere souvenirs of a principle inoperative in special cases?

Truly Tennyson was as much naturalist as poet when he sang:

Flower in the crannied wall,
I pluck you out of the crannies;
Hold you here, root and all, in my hand,
Little flower, but if I could understand
What you are, root and all, and all in all,
I should know what God and man is.

Deland, Fla.

WHITEWOOD

BY W. C. MOLLET.

The whitewood is one of the most majestic and noble-appearing of the native American trees, often reaching a height of 150 and even 200 feet. In the South it is generally called "poplar," although not a true poplar, but related to the magnolia, its specific name being *Liriodendron tulipifera*; hence it is often also called tulip-tree. It is found in most of the South and East, but reaches its perfection in about the latitude of Kentucky and Virginia.

The wood is very useful in a great many ways, as it is easily worked and capable of receiving a fine polish. It is also very strong and durable. On this account the groves of whitewood have been cut down to a considerable extent, so that the trees

are not as plentiful as they were some years ago.

It is also a very ornamental tree, as its manner of growth, its leaves, and flowers are very pretty, and it is one of the best and longest-lived shade-trees known.

It is not so hardy as the basswood in the North, and is also somewhat difficult to transplant, like all the magnolia family. The young trees will often bloom in ten years from the seed, although the blossoms are not very plentiful till it reaches the age of 15 or 20 years. It will succeed in any common soil, either moist or dry, and also on the hills as well as in the lower ground.

Whitewood is one of the best if not the very best honey-yielder with which I am

acquainted. The large flowers are of a cream color, with the base of the petals of an orange color, and they stand up straight like those of the tulip. They bloom in May or June according to the weather, sometimes very early, and at other times considerably later. When the blossoms come late, and the weather is fairly dry and warm, the honey-flow is very much heavier than when they bloom early. Under proper weather conditions no honey-plant will much exceed, even if it equals, the tulip tree. One good authority says that each flower will produce a teaspoonful of nectar, which I am pretty sure is not much of an overestimate.

On account of early blooming, and also the erect position of the flowers, the honey-flow is apt to be interrupted by cold spells or rain, which happens at least half the seasons. The tree continues to bloom nearly a month; and so when conditions are just right the yield is surprising, even where the trees are somewhat scarce. The bees often fill one or two supers from this source alone.

Where the trees are plentiful there is not much danger of overstocking, as I am pretty sure that 200 hives of bees could not take care of all the honey within their range. Unfortunately, there are very few such locations now, and they are generally in some almost inaccessible place where it is almost impossible to get out or in.

The honey from whitewood is a bright amber color when new, but it becomes darker with age, and also very thick—sometimes almost like molasses. It is always considered to be of a fair quality, and most people who are acquainted with it prefer it to any other. I always can get a good price for it, generally 15 cts. for bulk comb honey, as this is the most common way of getting honey here, and so there is no need of fussing with getting the bees to work in sections. As long as I can sell bulk comb honey at practically my own price I am not very likely to produce honey in sections, as I can get fully a half more in the extracting-frames.

Stonecoal, W. Va.

VALUABLE WINTER BLOOM

BY P. C. CHADWICK.

The loquat is very limited in its distribution. It is found principally in our city gardens, and is grown for its fruit. Nevertheless it is of considerable importance as a pollen and honey plant for the month of December, when little else to encourage a bee is to be found.

The eucalyptus is of vast importance in many sections of our state. There are many species of this tree, one or more of which may be found in bloom at a time, during the entire year. The picture is that of *Eucalyptus globulus* which is, perhaps, the most important of any in the state, due to the fact that it has been planted generally to a greater extent. *Eucalyptus robusta* is the next in importance. Both of these bloom in December, January, and February, and their importance as a winter stimulative agent is well known to our native beekeepers. A flow sufficient to cause the building of new combs is quite common in some localities. The honey is not very desirable, either in color or flavor. There are said to be some thirty varieties of this tree in California.

No. 1 in the picture is a bud just in the act of blooming. The cap, which is almost exactly the shape of an acorn-cup, comes off and the petals spread, making the bloom

complete. No. 2 is a seed-pod which has shed its petals. No. 3 is a bloom with half

The loquat encourages the bees when little else is present.

of the petals removed. No. 4 is a flower just coming to full bloom. No. 5 is a bloom at its fullest. The dark spot in No. 5 is where the bees enter for the nectar, the depth of which can be judged from No. 2. I have seen as many as three bees working on a single bloom at the same time. The fuzzy petals interfere with the progress of the bees to some extent, as they are obliged to work their way through to the honey-cup. They get well paid, as a rule, for their work.

Redlands, Cal.

The eucalyptus is of vast importance in California.

A NATIONAL COLLECTION OF HONEY-PLANTS

BY EURTON N. GATES, PH. D.

The Massachusetts Agricultural College, through the courtesy of the Botanical Department, Prof. A. V. Osmun in charge, has kindly consented to serve as a repository for specimens of honey and pollen plants from various parts of the country. The year 1915 seems to be devoted to the study of this subject, especially by the bee-keeping press.

It is, moreover, fundamentally important, and is so recognized by the progressive beekeepers, for only by a thorough understanding of the flora can the most successful honey-cropping be accomplished. From time to time the flora of a given locality changes. New honey sources appear. Some seasons one honey-plant may predominate; in another season, other plants may predominate. Furthermore, a given plant may yield nectar, as, for instance, alfalfa, in one locality and not in another. The reasons for some of these phenomena are not fully understood.

It is with a view to determine the range of honey-plants and the locations of their highest efficiency that this institution proposes to serve the beekeepers. In so far as possible, too, the institution will assist beekeepers in the determination of unknown honey-plants. Furthermore, specimens received according to the directions given

below will be filed in a permanent herbarium of nectar and pollen yielding flora. This collection should become invaluable as a source of reference during years to come.

Beekeepers are, therefore, invited to furnish for this collection, according to the following directions, specimens of their local sources of nectar and pollen.

Plants should be pressed and dried for shipping, as there is always danger that when shipped in fresh condition they will not reach their destination in good condition for preserving and identification.

DIRECTIONS.

1. Plants for pressing should be in full blossoms and should go into the press while fresh.

2. Newspapers may be used as driers, if care is taken to change them each day until the plants are perfectly dry, otherwise moldy specimens will be the result. Place the plant between several thicknesses of paper. If a plant is taller than the length of the paper it may be folded over to fit.

3. Use the margins of the newspapers on which to write necessary data, including name of plant—common or scientific—place and date of collection, name and address of collector, and a note of the value of the plant in your locality for honey or pollen.

(Extended remarks should be sent in a separate letter; but be sure to refer to your specimens sent under separate cover.) It is desirable that several specimens of each kind of plant be prepared.

4. Press papers may be laid on the floor with a board of the proper size on top. On the board place a weight (or stones) of about thirty-five pounds. Too much weight is not desirable.

5. For shipping, place the folder containing plant and data between pieces of binder's board or heavy cardboard; wrap and tie securely, and label "dried plants," with your name and address as sender.

6. Address the package to:

Prof. A. Vincent Osmun,
Clark Hall,
Massachusetts Agricultural College,
Amherst, Mass.

THREE SOUTH-CENTRAL HONEY-TREES

BY J. M. BUCHANAN.

Virgillia lutea, yellow-wood—a tree attaining a height of 75 feet, and a diameter of more than 2 feet, occurring on the highlands of the south-central states, and often planted for ornament. Flowers are snow-white, in large panicles 12 inches long; blooms in April and May. The honey has

Virgillia lutea, Yellow wood. Photo by J. M. Buchanan, Franklin, Tenn.

Robinia pseudacacia, Locust. Photo by J. M. Buchanan.

a strong, distinctive flavor, and, when mixed with locust, which it usually is, it forms a delightful blend.

Liriodendron tulipifera, yellow poplar. Found throughout the south-central states. This is one of our most valuable timber trees, sometimes standing 150 feet high, and 10 feet in diameter. Like the linden, it is becoming scarce in many sections. It is a heavy yielder of nectar, producing a fine-flavored, light-amber honey. The blossoms open in May; are large, tulip-shaped, yellow, with irregular red spots on the inner faces of the petals.

Robinia pseudacacia, black or yellow

locust. A rugged, homely tree, but a wonderful honey-plant. The creamy-white blossoms open in April, and fill the air with their sweet perfume, inviting the bees to come and feast. The honey is water-white, heavy in body, mild-flavored, slow to granulate. The yield is often heavy, depending somewhat on weather conditions. I have known a colony on the scales to store 15 pounds in a day from locust alone. The locust occurs in the central and southern states; and the wood, on account of its lasting quality, is valuable for posts. It is also a good soil-

renovator, as it is a member of the legume family.

Franklin, Tenn.

THE EUCALYPTUS OF CALIFORNIA

BY LESLIE BURR.

The tourist on his arrival in California probably obtains more misinformation on the subject of eucalyptus than on any other. The object of this article is to set forth the general characteristics and habits of the eucalyptus.

The tree is a hard-wood evergreen. It belongs to the order *Myrtaceae*, and is a native of Australia. The tree was discovered in 1788 and was introduced into California in 1856, the first tree being planted near Santa Barbara. The name "eucalyptus" was suggested by the lid or cap-like covering that covers the immature blossom, the word being from the Greek, and meaning "well hidden." There are about 150 species, more or less, of the eucalyptus, the number not being definitely settled.

The tree that predominates in California is the *Eucalyptus globulus*, commonly called "blue gum." In years past a possible ninety per cent of all gum-trees planted were *Eucalyptus globulus*. This tree has the distinction of being the fastest-growing tree in the world. This does not mean that blue gum will always grow more rapidly than any other gum-trees, for in many localities other species have outgrown it in particular instances; but, taken as a whole,

it is the fastest-growing tree. In 25 years it attains the size of that of an oak-tree whose rings show it to be 200 or 300 years of age. The wood is the equal of oak, and can probably be used for a greater variety of purposes. It has another added value in that, when it is cut down, the tree sprouts freely, sending shoots 75 to 100 feet high in from six to eight years.

All the species of eucalyptus are propagated from the seed only. The seeds are very small, the average size being about .04 of an inch. The number of seed produced by a tree is enormous; but, however, a very small percentage of the seeds are fertile, and for this reason there is a widespread opinion that seeds from trees growing in California will not germinate.

The blue gum and a number of other species are bark-shedders—that is, they continually shed their bark. The trees are also classed somewhat by reason of the nature of the bark, as iron-bark gums, stringy-bark gums, and white gums.

The localities where eucalyptus will grow here in the United States are limited. They do best where the summer temperature ranges from 80 to 100 degrees; and where in winter the temperature seldom goes be-

low freezing. This restricts the eucalypti to the warmer valleys along the Mexican border, and to California. Practically all of the varieties seem to do best in a semi-arid country. They grow without irrigation in California where there is but a few inches of rainfall. Some of the species will stand more frost than others, the amount of frost a tree will stand depending somewhat on the condition of the tree. If the weather has been cool for some time they will stand temperatures of 25 degrees to 20 degrees Fahr. without injury. Florida is a poor place for the eucalyptus by reason of the sudden changes in the temperature. In Government Bulletin 35, Bureau of Forestry,

ferent species of the eucalyptus are, by the general public, called blue gum; seven are called flooded gum; eight are called iron-bark; nine are called red gum; eleven different species are known as stringy-bark, and the name "white gum" is applied to thirteen different species. By reason of this dearth of common names the botanical names have to be used, and here it might be well to say that the botanical names refer to some prominent feature of the tree. For example, *Eucalyptus globulus* is so called from the globular seed-case. *Eucalyptus longifolia* is so called by reason of the long leaves. *Eucalyptus mellidora* means "honey-scented," from the fragrance of the blossoms.

Eucalyptus robusta is so called by reason of the robust appearance of the tree. *Eucalyptus sideropholia* means "iron-bark," and is so called by reason of the nature of the bark. *Eucalyptus diversicolor* is named from the varied color of the foliage, and the *Eucalyptus cornuta* means "horned" because of the horn-like cups over the immature blossoms.

There is considerable difficulty in distinguishing the different species of eucalyptus. In fact, it is admitted by the best authorities that it is practically impossible to distinguish them in many cases until the trees bloom and the seed-pods mature.

To obtain an idea of the vastness of the study of eucalyptus we have but to consider the fact that Baron von Muller spent considerable of his time for a period of fifty years in the study of eucalypti. He described about 100 different species, and recognized 30 more, but died before he completed his work.

The foliage of the eucalyptus varies considerably. In some the leaves are bluish, others grayish-green, and still others very dark. Some of the leaves hang edgewise to the sky, and some flat. In some species the leaves

on the young shoots are round or flat and opposite; but after the trees obtain a few years of age the leaves are never opposite. The prevailing shape of the leaves is lance-shaped and somewhat curved. The leaves of the different species vary considerably in length, being from three to fourteen inches long.

The blossoms of the eucalyptus are mostly white or greenish-white, there being exceptions however. Some trees have a brilliant red or pink blossom, the red iron-bark being one of the trees in the latter class. Eucalyptus can be found in blossom at all sea-

a, yate gum; b, red gum; c, blue gum; d, lemon gum; e, lemon gum.

Prof. McClatchie quotes as follows from Col. G. H. Morton, of Eustis, Florida: "All eucalypti do well, but are killed to the ground when severe blizzards come and mercury falls below 20 degrees Fahr. The trouble with the climate is, we have warm weather nearly all the time in winter, with an occasional cold wave."

There are very few of the species that have common names, and quite often the same name is applied to several species. According to Prof. McClatchie, twelve dif-

Apple, variety Hurlbut, *Malus domestica* B. Mill.
Photographed by John H. Lovell.

Red clover, *Trifolium pratense* L. Common, but not a reliable honey-plant. Corolla tubes too deep for most honeybees. Photographed by John H. Lovell.

Tulip-tree or white-wood, *Liriodendron tulipifera*. Leaves are dark green and glossy, flowers greenish yellow, orange within, solitary and erect. Photographed by C. V. Rice, Lawrence, Mich.

Orange blossoms and leaves. Photographed by Flora McIntyre, Ventura, Cal.

sons of the year, while others have several periods of bloom. The blossoms, as a rule, grow in clusters or umbels, very seldom being single. The blossom consists of stamens, these stamens in the different species varying from $\frac{1}{2}$ to $1\frac{1}{2}$ in. in length. There is always the cap over the immature blossoms, this cap being part of the calyx, and always coming off in one piece resembling a lid or cup.

As a honey-producer, a number of the species are profuse yielders. In examining the various authorities on the subject there seems to be no species but that some one claims it yields honey. So it seems a safe proposition to state that all of the different species of eucalyptus at some time or other, in some localities, yield honey. There is

considerable variation in the quality of the honey. Some is strong and rank, and of inferior quality; some of the nectar has a distinctive odor or aroma of the eucalyptus-tree, and is not disagreeable. In fact, some people after having eaten eucalyptus honey prefer it to good white honey from other sources.

The practical value of the eucalyptus to the beekeeper is that it furnishes pasturage for the bees when there is nothing else, the bees here on the coast this past winter having stored surplus from eucalyptus during December, January, and February. The value of the different species as honey-producers is as yet far from being exactly determined, even though the tree has been

recognized of value to beekeepers for a number of years. Prof. Kinney, in his work which was published some twenty years ago, states that his attention was first called to the value of the eucalyptus to beekeepers by Prof. A. J. Cook, Claremont. It is safe to say, however, that within the next ten years eucalyptus culture will make more progress than has been recorded in the past sixty years. It is the only tree that can be grown and show a profit per acre with other ranch crops. Each year, for the past few years, large tracts of land have been planted to eucalyptus; and in a few years, perhaps, eucalyptus honey will be filling just such a place in the honey market of the West as buckwheat honey fills in the East.

San Diego, Cal.

SOME NEW ZEALAND HONEY-PLANTS

BY W. B. BRAY.

1. *Fuschia*.—This is an ornamental garden variety. The bees work the red flowers vigorously. In New Zealand we have a native variety similar to this, only the flower is green. It is a great honey and pollen

yielder, and flowers for over three months, lasting well into clover bloom. It is a standby for spring feed, and is not affected by rain, the flowers hanging downward. The pollen is blue on all varieties.

Rain cannot get to the pollen on the fuschia.

Nectar can be shaken out of redhot poker in handfuls.

Bees always work the passion flower.

The Scotch thistle grows everywhere.

In New Zealand the catsear is sometimes called the dandelion.

2. *Passion Flower*.—This is a vine which in warmer climes produces the passion fruit. The bees always work it. It has a very long blooming period.

3. *Redhot Poker*.—A garden plant here; but in its native habitat the bees should do well on it. The nectar can be shaken out in handfuls. The bees work on it from early morn till late in the afternoon. It blooms in the early autumn here.

4. *Catsear*.—This is commonly called capeweed here, and even dandelion. Is it the same as is called dandelion in the states? Dandelion has a similar flower, but only one flower to a stalk, which is hollow. The leaf is smooth. Catsear has a rough leaf, and the flowers come on branching stems which are solid. Dandelion blooms in the spring, but catsear starts soon after clover and continues when clover is finished. The flowers close up after midday. It is a strong grower, and often the pastures are a sheet of yellow in the morning. It is a useful honey-plant. The honey is of a rich golden color, and the flavor mild and good.

5. The common Scotch thistle is a weed which grows everywhere. It begins flowering as clover is going off, and provides a quantity of water-white honey. The bees work very hard on it all day, and it is no uncommon sight to see several bees at once on a flower.

Wainin, N. Z.

THE GLORIOUS GUM-TREE; A WONDERFUL HONEY-YIELDING BOTANICAL ORDER

BY T. RAYMENT

An American architect came to Australia to design a capital worthy of the commonwealth. He, like all visitors to the Australian shores, was so deeply impressed with the unique beauty of the trees peculiar to the island continent that he enthusiastically described them as "glorious gum-trees." This note awakened Australians to a better appreciation of the indigenous flora. "The glorious gum-tree" is ubiquitous. Snow-gums (*E. alpina*), twisted and bent, battle with the elements on the snow-clad mountain peaks. The scorching winds of the arid interior do not debar the coolibah (*E. microtheca*) from flourishing. Color harmonies in deep cool forest gullies are provided by the manna-gums (*E. viminalis*) and cider-gums (*E. gunnii*). Other species clothe the long coast line, notably the swamp mahogany (*E. robusta*). Surely a wonderful distribution!

But the term gum-tree is a misnomer. The various trees belong to the species *Eucalyptus* of the order *Myrtacea*. E. R. Root, editor of GLEANINGS, once said that it was almost impossible to specify botanically the goldenrods (*Solidago*) of America, and this applies to the *Eucalypts*. They furnish an interminable study in plant gradation, one species merging into another with baffling complexity; but they all yield honey. The bark permits a popular classification because it is most apparent; but no system is entirely satisfactory. Here, then, are the groups differentiated by the bark:

Gum-trees.—Bark thick, smooth, and soft. Typical specimens, blue gum (*E. globulus*), and forest red-gum (*E. tereticornis*).

Box-trees (1).—Bark solid, rough, and short-fibered; confined to the bole with upper branches bare. Typical specimens, yel-

low-box (*E. mellidora*), and gray-box (*E. hemiphloia*).

Box-trees (2).—Short-fibered and rough, persisting to the topmost. Typical specimens, apple-box (*E. staartiana*), and red box (*E. polyanthemos*.)

Stringy - bark.—Bark thick, soft, and long-fibered, not unlike cocoanut fiber, completely covering trunk and branches. Typical specimens, messmate (*E. oblique*) and Gippsland stringy-bark (*E. eugenioides*).

Iron-bark.—Bark hard, brittle, dark, with deep furrows. Typical specimens, red iron-bark (*E. sideroxylon*.)

There are hundreds of species, some with a habitat extending over the five states, so that every week produces a honey-crop in some portion of Australia. The color of the nectar varies from water-white (*e. g.*; box) to a dark vandyke brown almost as deep as the color of buckwheat honey (*e. g.*, stringy-bark). Each little district has its special favorite species for pride of place as a honey-producer. You cannot imagine the honey resources of the province of Gippsland in Victoria. From where this is written the eye may travel over the tumbling contours of sixty miles of mountains clothed with unbroken virgin forest containing many species of eucalyptus. In this mighty sylvan

The gum-tree grows everywhere throughout Australia.

expanse, pulsating with the majesty of God, and permeated with the wonderful odor of growing trees, there are but two bee farmers. Adventurers? Yes, and one of whom is your humble servant.

Briargolong, Victoria, Aust.

[This is the first of a series of three articles by Mr. Rayment on certain important pollen and nectar yielding plants of Australia. The second article will appear in the next number. —Ed.]

THE BITTER HONEY OF THE SNEEZEWEED

BY H. A. MOODY

Last September I wrote GLEANINGS that some of my supers were full of beautiful bright-yellow honey, too bitter for eating. Inspired by that fraternal spirit characteris-

tic of all true bee-lovers, Mr. Herman Menly of Corpus Christi, Texas, wrote me that he once had some bitter honey, gathered from a tree called "la Retama," which he re-

placed upon the hives, and in 30 days the bitterness was all gone. I am much obliged to him for the suggestion; but my bitter honey came from a different source, *Helenium tenuifolium*, the sneezeweed or bitterweed of the South, a poisonous perennial which can be killed only by mowing it for two years so often that it cannot go to seed. It seldom kills cattle, but it makes the milk too bitter for use. It is a nuisance, for even when there is other grazing some cattle will eat it. I might say that, though it resembles dog-fennel (*Anthemis cotula*), it is of a different family.

Well, I put about a dozen bitter supers on the hives, next to the brood-chamber,

though some warned me it would kill the bees. I have just extracted those supers. All the yellow honey was gone, and they were filled with young bees and rich amber honey. Two supers were rejected, as they still had a slight bitter flavor. So there, you see, are two questions answered. It will not kill bees, for I lost but one colony in the eight months of my absence; and you can never be sure of getting rid of the bitter taste. I have never known it to be gathered when there was any other nectar, and if replaced on the hives all other honey should be taken away, so that they will be obliged to use it.

Florence, Ala.

THE COMMON LOCUST

BY J. H. BOWMAN

The locust yields much honey usually at a time when it is greatly needed by the bees. Ordinarily it blooms about the middle of April in Kentucky, although it sometimes blossoms late in March. This makes it of much value in building up colonies in the spring. Sometimes it yields a nice surplus.

The honey made from the locust is water-

white and of very fine flavor. Owing to the value of locust timber for fencing purposes it is being cut down very rapidly, and is decreasing in value as a honey-yielder. On the other hand the locust grows rapidly, and yields some nectar while it is very young—a partial compensation.

Mortonsville, Ky.

The fragrance and nectar of locust blossoms attract large numbers of bees.

An aged locust-tree in heavy bloom.

Bees on plum blossoms promise perfect fruit. Photographed by A. G. Lucier, Powell, Wyo.

Gathering nectar from plum blossoms. The bee can be plainly seen near the center of the picture: Photographed by A. G. Lucier, Powell, Wyo.

THE NEED OF EXACTNESS IN THE DISCUSSION OF HONEY-PLANTS

BY C. F. BENDER

All beekeepers seem to agree that buckwheat produces dark honey; that basswood and the clovers produce light honey. Outside of this simple creed it seems very easy to get up a discussion as to the color and quality of honey produced by any particular plant.

It is not always easy to say *where* the bees are getting their honey. I have had honey stored in supers when I could not even guess what plant had produced it, and that in a level country where I was familiar with every acre of ground, and rather well posted as to the honey-producing flowers and their season of bloom. But that is not the rule with me. Usually I know where the honey is coming from, if there is enough to make a show in supers, and sometimes I can be sure that practically all is from one source.

We often disagree on such matters because we are talking about different things. A brother in eastern Canada and one in Illinois have a talk about aster honey, and one says it is of light color and good flavor, and the other says it is dark and strong.

Neither describes the plant, tells the Latin name, nor even the color of the flower. Neither stops to consider that there are more than forty species of the genus *Aster* in the United States, and that of aster-like flowers, easily mistaken for them, there are many hundreds. It is easier for me to believe that the honey from related plants may differ in quality than to believe that the quality varies in the same plant in different localities.

Before I had ever made any careful study of plants I was skeptical about honey ever being produced from goldenrod, as I never could find a bee on it; but at Medina, Ohio, I found two kinds of goldenrod growing side by side, blooming at the same time—one a honey-producer and the other not, and both were different from our Illinois species. We have two species of Spanish needle here—one with gorgeous yellow flowers that the bees never visit; the other a modest flower that sometimes gives some surplus. In southern Kentucky I found bees on another plant of the same genus, quite dif-

ferent in appearance. People living there called it Spanish needle, and seemed surprised to hear that Spanish-needle honey in Illinois was produced from a different plant.

In speaking of heartsease I think beemen usually mean a plant of the knotweed or smartweed family. Yet Webster's dictionary says it means a violet or pansy. Even Dr. Miller, that careful teacher of bee lore, speaks of heartsease without other definition (p. 123, *Fifty Years Among the Bees*); but he gives a cut of the plant in another place which shows it to be a knotweed (*Polygonum*). It seems to be different from the honey-yielding species here, which is *P. pennsylvanica*. We have five species of polygonum growing in our township, four of them quite common. Only one of them is ever visited by bees. It begins to bloom a little in July, but does not yield honey until cooler nights come on, the flow lasting from August 26 to October. I often get a large crop from it when nothing else is yielding. The color is very light and the flavor delicious. Sometimes it is mixed with honey from our Spanish needle (*Bidens frondosa*) which injures both color and flavor.

Boneset honey is generally described as

dark and rank, but our variety (*Eupatorium scrolosum*) seems to produce a very good quality of honey. Wood's Botany gives the name "boneset" to *E. perfoliatum*.

There are even two kinds of dandelion to be found. The species at Medina is evidently a cultivated plant run wild, and is quite different from the wild dandelion of my locality.

I could give many other instances of the same name being applied to widely different plants in different places; but it would only be adding evidence to prove what is already proven—that in speaking of honey-plants we ought to give the Latin name if possible. A vast majority of plants have no English name; and if there is one it is often applied to other plants.

It is true that the busy beeman has little time for the study of botany; but it is easy to identify the common flowers with the aid of a few books. In cases of doubt the state experiment stations or the Department of Agriculture at Washington will help us out, if the plant is sent with flowers, leaves, and seed-vessels.

Newman, Ill.

ANOTHER FLORIDA BEE PASTURE

BY F. M. BALDWIN

Much of the testimony taken in courts is worthless because the witness has not learned how to see things. The man with real ability to observe is rare. Last fall I watched for the coming of the first bloom on the goldenrod and rejoiced when by the roadside, as I was at work surveying, I caught the first glimpse of a bee on it. To my rodman, who is an intelligent young man, I said, "See there!" as I pointed at the bee. He looked all around and said, "See where?" I was almost touching the bee, and I kept on saying, "See there!" It would have been easy to say, "Don't you see that bee?" but I wanted to test his powers of observation, and so I kept on saying, "See there!" As he was not thinking bees I was at last forced to say, "See that bee on that flower."

Mr. C. H. Clute has thought bees ever since, as a half-grown boy, he earned his first quarter by a day's work watching the issuing of swarms in Wisconsin. The beekeeper was busy with his farming, and he hired the boy to report when a swarm had issued. He has acquired the faculty of observing all things that concern these wonderful insects.

Recently he was in the country along the St. John's River, Florida. He reports a flora that actually seems too good to exist.

Hearing of some bees for sale near Sanford he went to see and buy, if he found matters favorable. Of course, as a careful man he looked closely into the flora of the region before he bought. Having satisfied himself on this point he bought three yards with nearly 200 colonies. Sanford is at the head of steamer navigation on the far-famed St. John's. He made the trip by boat down it to Jacksonville, closely observing the vegetation on its banks. He brings back an interesting list of what he found growing there. Below is a copy. After he gave it to me I went over it with Mr. J. J. Wilder, of Cordele, Ga. Wilder has the "Florida habit," and winters with us at Bradentown. He agreed with me that the list was worth publication, and that we could be sure it was carefully and correctly compiled. According to our ideas there are at least thirteen first-class nectar-secreting plants in the list. These are put first in the list and marked with a star. When I told Mr. Clute about what we had

GUAMA AND GUAVA AS HONEY-PLANTS.

The illustration shows a stalk of the guama in full bloom. This tree has had three periods of bloom this year. However, it is not the heaviest-yielding tree, for we have the guava, which is more abundant in nectar, and whose flora lasts several months. Moreover, the honey is equal to that from the guama or even better. Both of these trees are used for shade in coffee plantations.

Yauco, Porto Rico.

S. COLOM.

picked out as first class in this list he thought we had skipped several that belonged in the first rank. He would include maple, yellow jessamine, sweet fennel, touch-me-not, all-root, buck-apple, live-oak, Mexican clover, sumac, and titi. If you have no personal knowledge of Florida, you may think he has included several very poor honey-plants. But remember that what does well with you may be an absolute failure here and *vice versa*. Back in Indiana it was too cool for maple to give any nectar when it bloomed. Down here it starts the activity in the hive and lasts more than a week in the spring. It is not

strange that Mr. Clute would put it in the first rank. But I hardly felt that it was a "ringer," and concluded that I would stay with the classification that Mr. Wilder and I had made. Thirteen may in some cases be an unlucky number; but in this one it means success to the beekeeper who is fortunate enough to be located in such a neighborhood. It gives a succession of bloom the year round. What more can one ask, especially when it includes such fine producers as orange, saw palmetto, Spanish needle, tupelo, and the myrtles?

Mr. Clute put up his surplus in Mason quart jars as chunk honey, and brought home with him some of it as samples. The one that most interested me, because it was new to me, its color so peculiar, and its flavor so fine, was mint honey. From one of the yards southeast of Sanford he took 1800 pounds of this kind. Dividing 1800 by 30, the number of colonies in the yard, gives 60 as the average. For a yard where there had been lack of room

owing to the owner's being engaged in what he thought more profitable business, sixty pounds is a good average. But friend Clute expects to more than double it this season, the prospects for a heavy flow being the best ever known at this time.

He has picked a location half a mile from the present one, where this yard should gather from smartweed as well as from mint. This last comes in and goes out before the other begins, and this other yields for months, beginning in July and staying with us until late in November. There are acres and acres of both mint and smartweed. Before smartweed fails, wild sun-

flower, goldenrod, and myrtle come in, and there is the greatest profusion of them. Does not this look like a beekeepers' paradise?

There are fifty plants in this list; but they ought to be separated into the different varieties, in a number of cases, to give one a correct idea of what a multitude of sources of nectar this favored region has. Surplus was already being gathered the first of February, 1915. Why, drones flying on the St. John's, and we who are miles south of it had no sign yet of drones in our hives! The orange and the grapefruit were starting to fill the air with their delicious fragrance. I saw the first bloom Jan. 31. Our bees must hurry if they get in good condition for that bloom. Saw palmetto usually comes in about April 1. I was told that already there were blossoms on some of those plants.

HONEY PLANTS FOUND ALONG THE ST. JOHN'S RIVER, FLORIDA.

*Orange,	Basswood,
*Grapefruit,	Pennyroyal,
*Galberry,	Touch-me-not,
*Saw palmetto,	All-root,
*Smartweed,	Huckleberry,
*Mint,	Buck-apple,
*Partridge pea,	Yellow daisy,
*Goldenrod, 4 varieties,	Persimmon,
*Wild sunflower,	Prickly ash,
*Spanish needle (blooms almost all the year);	Live oak,
*Tupelo,	Water oak,
*Swamp laurel,	Bay,
*Myrtle (several kinds, two of which yield heavily in spring and fall.	Woodbine,
Maple,	Chinkapin,
Willow,	Hickory,
Rattan,	Black haw,
Yellow jessamine,	Mexican clover,
Cherry,	Mexican pinkvine,
Aster, several kinds,	Watermelon,
Swamp dogwood,	Cucumber,
Locust,	Water hyacinth,
Yellow poplar,	Sheep burr,
Red shank,	Sumac,
Sweet fennel,	Titi,
	Grape, wild (good honey-plant in Florida).

Bradentown, Fla.

IMPROVING ON NATURE

BY G. DE C. CURTIS

I hived a swarm that had a virgin queen April 16; and when I examined them about a week later the queen appeared to have been fertilized, but was not laying. I noticed at the tip of her abdomen a small grayish-white deposit that looked like a bit of dried mucilage. Several days later (April 19) I looked in again, and there was still no brood. While I held the frame in my hand the queen went through the motions of trying to lay an egg. The bees stood around her expectantly; and when she moved on without depositing anything they followed her in a disappointed sort of way.

I decided on an operation. Holding her by the wings I pulled the adhering matter away with a pair of tweezers. It was stuck so firmly that her abdomen stretched out with the strain until I feared something would break; but when I looked into the hive again next day she seemed to be in good condition, and had laid a nice patch of eggs. Could it have been that the organ of the drone had not been removed, for some reason, until it had become so dried up that removal was impossible?

On the same day I saw a virgin hatch tail foremost from a cell in a queen-cell protector. I had examined the cell two days before, fearing that it had become chilled. I had made a tiny hole in the end of it, and, looking in, I saw the queen's black eyes shining, and a slight movement, so I put it back in the hive. Next day the bees had completely sealed over the hole I had made.

When I looked, on the day after that, the virgin was very much alive and trying to get out, but the hole seemed to be too small—perhaps the bees had sealed up the end too effectively. A number of workers seemed to be very much interested in the case—perhaps they were feeding her.

By the time I had carefully brushed them away the virgin had turned around in her cell, so that the tip of her abdomen projected from the hole. She might have been eating the royal jelly at the base of the cell. I took the cell out of the protector, and then with my queen-clipping scissors I carefully enlarged the hole in the cell; and when I had done so she backed out. The activity she showed as soon as released was like that of a virgin which has been held back in her cell by the bees beyond her hatching-time when bad weather or some other cause had prevented her swarming.

Foster, Cal.

[It may be that the queen did turn around while in the cell; but is it not more likely that she had hatched and then had gone into the cell again, head first, for the royal jelly and the "hinged door" (the cap of the cell) had closed after her? A number of such instances have been reported. The bees, seemingly unaware of the true state of affairs, wax the cell shut again, thereby making a prisoner of the queen.

Is it possible for a virgin queen to turn around, end for end, while in the cell?—Ed.]

Heads of Grain from Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

Don't think that you are the only one that has the blues on a cold wet day. Every bee in the yard feels the same way.

A Sting-proof Dress.

I must tell the women who have "bees in their bonnets," and yet are actually as afraid of a bee as they are of a mouse, about a suit so bee-proof in its construction that they may associate with bees to their hearts' content without a sting.

Make a garment of gingham or any light-weight material, just like a child's sleeping-garment (except a size too large). Don't shape the neck or shoulders, but extend on straight like a sack, several inches above the head; hem the top and run a good elastic in the hem. Cut out a place for the face and replace with fly-screen wire. Hem sleeves and bottom of legs, and run elastic in the hems so it will fit tight around the wrists and ankles. Take fencing wire; make hoops, and sew a few inside the garment, one at the neck to keep the garment away from the body so the bees cannot sting through.

You will not have to wear many clothes under this garment, as working with bees is such hot work. You get into the garment at the top, then put on a hat, and let the elastic in the top of the garment fit tight around the crown of the hat. Then there is not a crack or crevice where a bee can get in.

Of course, after you become acquainted with bees you will find the work very fascinating, and will discard all extra garments or wraps of any kind except occasionally a veil. But the garment described is fine for getting acquainted with bees.

CILA SEVER.

Pollen Dust on the Backs of Bees—How Did It Get There?

I have occasionally seen a honeybee with pollen on the back of the thorax. Recently, in examining a small colony, I was surprised to find all the pollen brought in exactly in that manner. I watched the bees coming in for a long time, and saw only one bee that had even a suspicion of pollen on the legs. The bees that were bringing in pollen had masses on their backs, some of them quite large. I am wondering if you had a similar report, and I also am wondering how the bees pack the pollen on the back. I chloroformed a few, and am sending them to you in a box by to-day's mail. In chloroforming them I noticed it took out the color of the pollen, which was a pronounced yellow, and also dissolved some of it, or at least flattened the masses on the backs.

I fancy that somebody may pop up and inform me that bees, in squeezing into the flowers, rub off a little on their backs. I have occasionally seen that powdery form, but these were evidently deliberately made pollen masses equivalent to those usually carried on the legs. Can anybody explain how the bees pack pollen in that position?

EDWARD F. BIGELOW.

Arcadia, South Beach, Conn.

[It is quite a common occurrence to find pollen on the backs of honeybees at certain seasons of the year. It is evident that the bees do not take the time to brush it off while in the field, but allow it to remain there, and then the dust is taken off after they get back to the hive. Sometimes these little patches of pollen are very conspicuous on the backs of the bees.]

Your last paragraph explains how the pollen in most cases gets there. If you examine some of the flowers you will find that the pollen masses are arranged in just such a way that it will daub up the backs of the bees. The bees are evidently after the honey, and, pushing into the flowers, they are compelled to brush against the pollen masses.

Referring to the samples of bees you have sent it looks as if they packed the pollen on their own backs.—ED]

Do Drone Larvae in Queen-cells Ever Mature?

A few days ago I examined a hive and found the usual signs of an infertile queen. On one frame the bees had built seven queen-cells on drone comb, each one of which contained an unsealed drone larva. As far as my observation goes, drone larvae in queen-cells die soon after being capped over. I shall be glad if you can tell me if there is any recorded instance of drone larvae under such conditions having reached maturity. I am told by an old hand at the craft that he actually witnessed this on one occasion, the result being the most extraordinary-looking bees he had ever seen. Unfortunately he did not preserve them.

J. B. SHEPPARD.

Apiary Inspector.

Nelson, B. C., June 26.

[There have been instances recorded where drone larvae in a queen-cell reached maturity; but usually the highly concentrated food seems to be too much for the poor beast, and he dies. In this connection, brood from a laying worker or drone-laying queen in ordinary worker cells will often be neglected. It will die about the time it caps over, smells horribly, and gives one the impression that it is either European or American foul brood. Such brood does not always die, but it frequently does. The cause

of death is neglect or starvation. It is a case of what we call "neglected brood." The bees evidently know that this brood is good for nothing, become discouraged, lie down on the job with the result that there may be a stinking mess in a short time.—EDJ.]

Importance of Italian Blood in the Cure of European Foul Brood.

Mr Root:—Replying to yours in reference to editorial on page 480, I may say that the instructions for the cure of European foul brood given in the Ontario Bulletin, 213, on "Bee Diseases," may be outlined as follows:

First.—The same treatment already described for American foul brood is effectual if applied to the whole apiary at once, but the cure is permanent only when pure-bred Italian queens are introduced to all black or hybrid stock.

Second.—If the colony is strong, and only then, another treatment may be employed. Remove the queen, then in ten days introduce a vigorous young Italian queen, and by the time she gets well established the disease will be cleaned up. If the disease returns in an Italian colony to such an extent that, say, half the brood is dead, removing the queen for five days before introducing a new one works well, as it gives the bees a chance to clean up the combs before the new queen has a chance to lay. If more than half the brood is dead, the colony should be treated by the McEvoy method.

The experience of some of our most careful men is that, if a beekeeper has his apiary Italianized before the disease reaches him, and if he is looking into his brood-chambers every week during the season, he need never destroy a single comb. The great trouble is that the vast majority of beekeepers, even the more extensive ones, are like the writer of the letter from which I am taking the following extract:

"*Dear Sir:*—I am really afraid that my bees are affected with that dread disease European foul brood. The first I noticed was about ten days ago. In looking them over I noticed two or three colonies that did not look right. Colonies that were healthy then are affected now. If you could send me some good man who could tell me if I really had the disease, so that I could start to Italianize at once, you would greatly oblige. I have about 250 colonies, the majority hybrids, about 25 pure."

The point that I wish to make is that this man has been reading our bulletins regularly, in which we have sent the most vigorously worded warnings against danger of continuing the use of black bees. He has been told that European foul brood was in his vicinity. In spite of that fact he is not willing even yet, when he feels quite sure the disease is in his apiary, to order queens and Italianize his apiary until we go to the expense of sending a man there to show him and tell him what he already knows. On the other hand, we have successful extensive beekeepers who have been treating a few cases each year for the last three years, and have never melted a single comb for the purpose of curing European foul brood. I trust that this will also answer Dr. Miller's question in your July 1st issue.

Guelph, Can., July 8, 1915. MORLEY PETTIT.

[Quote in line with this is a letter written to our State Inspector N. E. Shaw at Columbus, by W. C. Eastman.]

Mr. N. E. Shaw:—Replying to your inquiry regarding European foul brood that appeared in my yard last season I am pleased to report that I have the yard almost entirely cleaned up.

A year ago I had over 100 colonies of bees, mostly blacks, a large percentage of which showed more or less European foul brood, some of them so bad that I could not save them.

Acting on the advice of those having had experience I decided to try requeening with best Italian

stock as a cure; and as I was determined to do or die I ordered queens for every one not containing a pure Italian queen, and succeeded in introducing nearly all of them. The new queens were introduced as soon as the old one was removed, and the cure seemed to begin at once, as the Italian brood seemed to be almost immune.

All combs were saved and used as if no disease existed and more trouble was expected; but this spring only three colonies showed the disease, and two of them were blacks that did not accept Italian queens. The other is an Italian colony that probably had some very bad combs. The blacks were requeened; and one of them being left queenless for about two weeks showed very little disease, and the others are fast coming my way.

On combs that were fairly rotten last year I have now the strongest colonies I ever owned, many of them covering 30 L. frames with two supers added. Perhaps not all Italian bees are as immune as these.

No colonies were lost after requeening, and over 90 queens were accepted.

Rock Creek, O., June 21.

W. C. EASTMAN.

Bees on Dogwood.

In the past fortnight, when clover-time has been an actual honey-famine because clover had no nectar and locusts had no bloom, I have seen my bees working for honey on the cornel, otherwise called dogwood. There are different species of *Cornus*, blossoming at somewhat different dates, several of them fairly common, both wild (most of them near water), and in ornamental shrubbery (where they seem to thrive, water or no water). I cannot see that they have much nectar or any place in the flower where they could put it; but they seem to be some resource in a time of stress like this. These true dogwoods are no more relation to the "poison dogwood" than a horse-chestnut is to a chestnut, or a bee-martin (kingbird) to a real martin such as lives in martin-houses. I have heard authentic-sounding stories of people being poisoned by the "flowering dogwood," a true dogwood flowering in May, but I never fairly believed them.

Ballard Vale, Mass.

STEVEN T. BYINGTON.

Cold Weather in the Midst of the Honey-flow.

Conditions and weather here are about the same as in other western states. It was cold and windy up to June 15; then for two weeks we had a good flow; but it has again turned cold and cloudy, clearing at night, with light frosts in the morning. But in spite of the cold the flow continues good. Alfalfa is in full bloom, and very fragrant. I have never before experienced such a cold spell coming in the midst of the honey-flow without the flow being checked. Nevada seems to be an exception.

Reno, Nev., July 6.

M. W. HARVEY.

Good Record for an Old Queen.

Three years ago I started as a novice with one colony and the *A B C of Bee Culture*. I increased this one colony to four, and that winter bought three colonies that were starving from lack of stores.

In 1913 I increased my seven colonies to fourteen, and got 900 pounds of comb honey. This took the blue ribbon at the mid-winter fair.

In 1914 I increased to thirty-three colonies and took off 11,000 pounds of comb honey, not counting the fall honey-flow. How is this for a queen four years old?

OUR HOMES

Editor

Her price is far above rubies.—PROV. 31:10.

Train up a child in the way he should go, and when he is old he will not depart from it.—PROV. 22:6.

By invitation I gave a talk to the Wooster summer school of teachers (mostly schoolm'ams) at Wooster, O., the suggested topic being "Some Lessons of Eighty Years.*" As I am not quite 76 years old I cannot very well go back as far as eighty years of *personal experience*. I have a dim recollection, however, of something that occurred 72 years ago. I remember a broad open fireplace with a brisk warm fire, for it was winter time. I was supported on warm pillows in a rocking-chair. At the right and left and back of me thick warm blankets were hung up. How did I come to be in this predicament and with such surroundings? Well, some days before, I had caught cold, and I think I had an attack of croup. Our family doctor was called; and as he went away he said:

"Do not let that child even so much as look out of doors, for he is threatened with lung fever."

Well, not long after the doctor's visit, preparations were being made to brimstone a hive of bees to get the honey. Let me remark here that my good mother had said that at even that time of my life I was a great hand to ask questions. I wanted to know the whys and wherefores of all the wonderful things going on in this teeming world. I had tasted honey, and asked *where* the bees got it and how they got it. Then when they talked of killing the faithful and industrious little insects I had a lot more questions. I asked if there was not some other way, and where they would get more bees to gather honey the following summer, etc.

Notwithstanding the doctor's orders, even if I knew of it, in my enthusiasm to know more about the bees I forgot or ignored it; and when the wooden latch to that rustic door of the little log house was "unketched" I pulled the door open, and, childlike, pushed out to see what they were doing with their shovel of coals and brimstone.† I stubbed my toe, or slipped on

*With some changes I propose to give this talk, and I hope my good friends will pardon me if I tell *another* some things that I have already given on these pages in the past. To make my story *continuous* I cannot very well *avoid* these repetitions.

†Please remember that friction matches were not invented at that early day. The only way to start a fire was the old-fashioned flint and steel, or go to the neighbors for a shovelful of coals; and it was setting a shovelful of coals out of the old fireplace to brimstone the bees, probably, that aroused my curiosity.

the snow, and the first thing the crowd around the hives knew of my presence was to find me fallen down, with my hands sprawled out in the snow. By this time my mother or one of my older sisters was asking, "Where is the baby?" I was carried in and placed in front of the fire as mentioned above. I grew rapidly worse, and *finally* a *council* of doctors was called. But they said it was too late—the child was past help; his falling down in the snow was more than he could stand in his frail condition. They gathered up their medicines, and told my good mother there was no use of their coming any more; the baby would not likely live till morning. But *mother* did not give up. Did you ever know a mother to give up? She watched over me, and in the stillness of the night prayed that the little spark of life might be kept going. After days and perhaps weeks of untiring care and devotion her prayers were answered. Some one inquired which one of the three doctors had succeeded in pulling me through. The doctor replied, "No *doctor* and no *medicines* saved his life. It was the mother's love and the mother's prayers." "Her price is far above rubies." I lived; but I was a feeble child, not only for months but years. When I went to school they laughed at me and called me "Pipestem." But although I was pipestems physically I could keep up with any of the rest, mentally. As soon as I was old enough I was taken to Sunday-school; and I one sabbath astonished the class by repeating forty verses of scripture; and when the older children laughed at my unending curiosity and odd questions, mother used to say, "Amos, when he grows up, will be just as smart and capable as any of you. You watch and see."

As a consequence she gave me, perhaps, more loving care than any of the other six who were strong and healthy. Some good doctor told her to keep me in the open air as much as possible; and this is why I have always been so fond of gardening and seeing things grow. She taught me to care for the chickens, and told me all she could about bees.

I think I was between nine and ten years old when I found a chapter on electricity in our old doctor book. At that time we had so few papers and periodicals in the home that I had at that age read over pretty much everything in print to be found in our humble home, including the dictionary and the "doctor book." I was so excited

about what I found in regard to electricity that I soon had a home-made battery. It did not work, however, as I expected, and I applied to the family doctor and to my schoolteacher. When I got hold of Parker's Natural Philosophy I was almost wild with delight. I shall always remember the evening when I first got my battery to work. A traveling lecturer had magnetized my knife, and with it I had made a magnet of a good-sized steel pen. It was balanced on the head of a pin driven into the table. Now with one of the battery wires laid on the table just under the steel pen (that was pointing north) I could make it swing around by making and breaking the electric current through the wire; and when I could make that magnetic needle bob back and forth by simply touching the wire at *the further end of the room* I was delighted beyond measure.

A little later the principal of our Mogadore schools made me a present of an old book called "Conversations on Chemistry." I read it over and over, backward and forward, from beginning to end.

When I was thirteen years old an uncle invited me to spend the winter with them at Wellsville, on the Ohio River, promising to give me all the advantages of the Wellsville high school. Before deciding in what department I belonged, the superintendent put me through an examination. As he did not mention natural philosophy and chemistry, and knowing they had a fairly well-equipped laboratory, I asked if I could not have chemistry and philosophy with my other studies. I noticed a sort of smile on his face as he questioned me in regard to these branches; and I took great pride in "showing off" my acquirements. When he decided that for the present I had better stop these scientific studies I protested. He replied something as follows:

"My young friend, did you ever see an apple-tree with great branches all off on one side? May be you have seen such a tree after the wind had blown it over because it was 'lopsided.' Well, you are like that tree. You have been following your own bent in these studies that usually have a place later on, until you are 'lopsided.' Just now you particularly need grammar."

When I replied that I did not *like grammar* he laughed and said:

"That is about what I expected, and it is *our business here* to help you to *like grammar*."

Then he took me into one of the rooms and brought me to one of the women teachers. At first sight I was drawn toward her,

for I thought she looked like my good mother, and I was just getting homesick, especially when I was told I could not study chemistry and electricity nor go into that laboratory which had been in my mind's eye since the first thought of going to Wellsville. The superintendent said, "Miss Udell, here is a young man who thinks he does not like grammar. Now, I hope you will be able to persuade him while he is with you that he *does* like grammar."

She put out her hand to me with that kindly smile of hers, and said she felt sure we should be good friends anyway. Then I made a mental resolve that, if we did not get to be good friends, it would not be *my* fault. Through that four months of schooling the prospect of getting a glimpse of her encouraging smile was the strongest incentive to work while at my studies. At that time, over sixty years ago, we used to "go up" in the grammar class as we did in spelling. I remember the superintendent coming in after I had been a few weeks there, and saying to Miss Udell, "Oh! how about that boy who did not like grammar? How did you two get on together?"

With some pride, no doubt, she pointed to me and remarked smilingly, "He is at the head of the class, as you see, and stays there; and he is making remarkable progress in all his studies as well as in grammar."

Let me pause a little here. Suppose that at that early age I had been allowed to have my own way, and study what I liked, and skipped grammar. Imagine, if you can, the predicament of the editor of a family journal that goes over all the world, and yet who has never studied grammar! I do not know but some of the other pupils thought Miss Udell was partial to me, and gave me more of her time and attention than she did the others; but if so it was because I tried so hard to please her; and I thank a kind Providence that it has always been easy for me to learn *anything* when I get right down to it and work hard.

Miss Udell, bless her memory, was not the only schoolteacher who made friends with me and gave me a helping hand; and as a consequence I can most devoutly say, as did King Solomon, of the good bright "school ma'ams" all over our land, "Her price is far above rubies."

I attended Sunday-school faithfully until I was about eleven years old. When I was four years old my parents moved into Summit County, where my mother's father gave us a home. Our circumstances were such that it was a task on the part of my good father to provide for a family of seven; and my oldest brother, who was but a little more

than a dozen years old, found work in a pottery. Some of the men in the shop were not only profane, but they were well known as unbelievers in the Christian religion, and they poisoned this young brother's mind until he stopped going to Sunday-school, making him think it was only a place for little children, etc.

Let me put in a word of warning to parents right here. No matter what *price* may be offered, do not let your boys (or girls) go to work under the influence of ungodly men. I am sure my mother demurred and protested; but father thought he could not keep so many unless they helped to earn a living. Finally my brother and I, when we stopped going to Sunday-school, wandered off into the woods Sundays and got among bad associates. Father had often expressed a wish to leave the village home and go back to the farm in Medina County; and I think he gave as one reason that he thought his growing boys would be better off on the farm back in the woods. We accordingly moved back when I was a dozen years old. But my good father failed to calculate that there are bad boys in the *country* as well as in the town and cities. I have already mentioned how he finally laid down the law and told my brother and me one Sunday morning, "Choose ye this day whom ye will serve." I have told you about how my brother finally turned the scale and recommended that we both go to church, at least for once. I have told you, also, that on that eventful Sunday I got about the first glimpse of Mrs. Root. She was one of the singers in the choir. By the way, friends, as you may have already discovered, I have been all my life greatly given to hobbies; and I sometimes ride these hobbies fast and far. The traits of childhood, the desire to investigate and find out all that is to be known about the wonders of God's creation, have followed me through life, and some of my happiest moments have been, perhaps, when I was investigating and exploring, to the further limits, some of God's creation. I believe I have always had a peculiar liking for the other sex. My good mother said that when a child I always preferred to play with the girls. The boys were, as a rule, too rough for me. Through my youngest sister, who was a very close friend of Mrs. Root in her childhood, I soon became acquainted with Mrs. Root. The reason I had not known her or of her was because I had been away attending school as mentioned above. Fifty or sixty years ago it was the fashion for boys of sixteen or seventeen years to go "courting" the girls. The two usually had

a room by themselves, and often stayed there far into the night unless some good father or mother interposed. In due time I got in the habit of going home with her who is now Mrs. Root, after church; and when it was time for *me* to go home I did not seem to know it. One Sunday evening Mrs. Root said to me, "You are going to school, and I am going to school. Our good parents are trying hard to give us the benefits of an education. It is time for you to go home so that both of us can get the rest we need, to give proper attention to our studies."

I did not like the idea of being dismissed, and finally declared that if I went home *then*, I never would come back again. Kindly but firmly she told me that in such a case it would be better for her, at least, if I did not come back. I said, "All right." I went out and closed the door in a not very pleasant frame of mind. I started down the hill toward the river, with long strides. But my strides kept getting shorter and shorter as I reflected. When I approached the river bridge I came to a standstill. I reflected for a minute. At that time I had not found that precious text at the head of our talk; but I did reason, perhaps, that my dismissal indicated, at least along the line of the text, "her price is far above rubies." I started slowly to go back. I walked faster, and finally hurried up to the front door that I had just left. Her room was upstairs, and her window was over the front door. I picked up a little pebble from the walk and tossed it against the window-pane. The sash went up as I expected it would, and I said, "Sue, forgive me. You are right and I wrong;" and in her usual way she simply said, "Thank you; good night," and then the window went down. How many girls are there who are reading these pages who have the good sense (especially at fifteen) to do as Mrs. Root did?

After this it was pleasantly understood that I was always to go home at a particular hour. But I not only made my calls on Sunday evenings but also on Thursday evenings, and sometimes *between* times. I attended to my studies and was making fair progress; but Mrs. Root did not learn as readily as I did. My frequent visits interrupted her studies. She had the good sense, even if I had not, to know that we both were *too young* to keep up any such fashion of being together *so often*; and finally she soberly and kindly, but perhaps sorrowfully, told me that she felt sure it would be better for both of us to stop our frequent visits together for some time—

perhaps several years. I protested, and I do not know but I threatened again; but she declared her conscience told her it was best. I asked her to set the time, say within two or three years, but she refused to do even that. She said we both were quite liable to change our minds before we became of marriageable age and it would be better to leave it with no pledge or promise. Then I went off into the "cold empty world," as thousands of other boys have done under similar circumstances. If you want to know how many men and women commit suicide just because they have been disappointed in love, look over the daily papers. Other young men and boys, I am sorry to say, go and get drunk, and say they do not care *what* becomes of them. I did neither. I just decided that, if I could not court the girl I loved, I would court *science* and become a "great man."

During the winter that followed, I studied harder than ever before. In school, in addition to the common studies, I had algebra, geometry, and shorthand, and was making experiments in chemistry and electricity during the evenings. In order to get exercise so that I could stand so much study I walked two and a half miles to school and back again, and cut all the wood to replenish the fire for the family, and while I experimented sometimes late at night it did not hurt me a bit. The walk through the woods developed my bones and muscles so they did not call me "Pipestems" any longer.

Now right here let me tell you something that will more fully illustrate Mrs. Root's good sense and wisdom. A fellow-student—in fact, a young man with whom I was intimately acquainted, told me, in speaking of what I had accomplished during that one winter, that *his own* schooling was just about a complete failure. When the school first opened he got in with a class of boys and girls who called themselves the "Euebre Party." They got into such a craze for playing cards that they spent about all their time, not only during the day but late at night, in card-playing—an occupation that amounted to nothing or worse than nothing; and when they came to recite they were just a drag on the school. Years afterward this man realized what he had lost by *wasting* the best hours of his early manhood. His good father and mother worked and scrimped on the farm to provide the means for him to go to town and attend school. Do you wonder that I feel pained whenever I see or hear of *card-playing*?

Another point comes in right here: The average boy or girl is far better off in the

home under the father's and mother's care, especially when getting an education. My tramp of two and a half miles every night and morning, and the muscular exercise given by chopping firewood, were *splendid investments* when I was just turning from boyhood to manhood. The parents of these card-players paid for their board, and they had a room of their own, so they (boys and girls both) could sit up *all night* if they chose, and no one were near to hinder.

THUNDER AND LIGHTNING! ELECTRICITY, GALVANISM, ELECTRO-MAGNETISM! MAGNETO-ELECTRICITY!

Attention, Ye Masters of the Sublime and Beautiful!

Admission 10c. Children under 10 years, 5c.

Doors open at 6 1-2, and commence at 7 1-2 o'clock.

Photographic copy of A. I. Root's "program," as he had it printed when he was 16 years old—almost 60 years ago.

I wrote several articles for the *Scientific American* before I was seventeen. These were accepted and published. In the mean time I began to go into the country school-houses and give talks and experiments. The idea that a *mere boy* was giving lectures attracted attention. I had full houses, and

with the money I received I was able to purchase better and more up-to-date apparatus. A few days ago the editor of our *Medina Gazette* sold out; and in removing some stuff from the office he ran on to an old handbill printed almost sixty years ago. On the preceding page is a copy. You will notice there is a blank before the name A. I. Root. Do you want to know what word occupied that blank? It was "Prof." Mrs. Root was still keeping track of me, although it was rather at arm's length. She objected to the word "Prof." and asked me what I was a professor of. I told her I was a "professor of electricity and chemistry," and that "folks wouldn't come" unless I put on—"Professor." Just think of it, friends—"Prof." of electricity and chemistry at the age of sixteen! Did you ever?

Before I was quite seventeen I decided to go off into the big wide world. My father laughingly told me he would have to send me money to get home with before I had been gone a month. I replied:

"Possibly you will, father, but just wait and see."

My father's little prediction did me good. I doggedly determined that, come what would, I would not send for money to get home. My first trip was out in the western part of the state in what is called the Black Swamp. I fell sick and got out of money, and had to leave my apparatus at a hotel. Between sundown and sunrise next morning, on one occasion I walked 24 miles to reach a sister of mine who lived in Elmore,

"When I, a few days ago, held up that old program before Mrs. Root, she immediately centered her gaze on the "Prof." before the name A. I. Root, and said "Please cut that out before anybody sees it."

"But," said I, "why. Sue, that was put on there sixty years ago."

"I do not care how many years it was—cut it out before anybody sees it."

"But I was only sixteen years old when I ordered this bill printed that way."

"I do not care whether you were sixteen or sixty—I would not want anybody to know that you were ever so foolish at *any* age."

"The lapse of sixty years' time doesn't seem to have changed her convictions very much. She "is of the same opinion still." I did as she directed, as you see; but I did not tell her I was going to have it printed.

Now just a word in conclusion. There is a great deal said about "emeralds" just now. The education of young men is being called to the fact that the kind of boys and girls they give the world depends largely on the *girl* they choose for a wife. If you want your children to be a blessing to the world, instead of helping to fill our penitentiaries and asylums, consider carefully before you choose. If you want a partner for life whose price is "far above rubies," do not look for her in the dancehall run at the card party, but, rather, seek to find her in the church, in the Sunday school, Pledge society, etc. Some girl singing in the choir of some country church will very likely be the one in after years to show that "her price is far above rubies."

Ottawa Co., but I finally came out ahead, and when I got home about a year later I had some money in my pocket.

In order to keep my apparatus in repair I often called on jewelers in towns I passed through; and at one place I took a little rest and paid a jeweler \$25 for two weeks' instruction in repairing clocks, watches, and jewelry. When I was 19 I was sufficiently expert so that one of our Medina jewelers asked me to care for his shop while he went east to buy goods. During the 4 or 5 years that had elapsed since Mrs. Root had dismissed me I had seen but little of her. I thought it was her business to send me word saying I might come back. But she evidently did not propose to do anything of the kind. While I was taking care of the store mentioned, one day Mrs. Root opened the door and looked in; and when she saw me instead of the proprietor she hesitated and said: "Why, isn't this Mr. Herrick's shop?"

I replied, "Yes, this is Mr. Herrick's but I am taking his place for a few days while he has gone east."

She was about to close the door and go away; but I ventured to suggest that perhaps I could wait on her. She finally came back, saying she simply wanted a piece of jewelry repaired. After that had been attended to I ventured to ask her if she was staying in town. Without looking up she replied that she would probably stay with her sister (who lived in town) over night. Then I ventured to ask if I might deliver the piece of work in the evening. At this she ventured to look up, and her eyes met mine. She replied faintly, "If you like." I knew then, and she knew, that the "embargo" was raised. That was the night of the terrible frost, June 4, 1859. The next morning the landscape was white with hoar frost. The wheat was killed, the fruit was gone, and the gardens were ruined. The price of flour went up to an extravagant figure until people got over their fright. Now, when everybody else was sad and sorrowful my heart was light, and I was as happy as a bird. The "cold empty world" was past and gone. What did it matter whether we had frost or cyclones, or even earthquakes? She whose "price is far beyond rubies" had linked her life with mine, until death should separate; and may God be praised for having *permitted* us to tread life's pathway together for more than 54 years. Most faithfully has she kept *her* part of the pledge.

HIGH-PRESSURE GARDENING

THE SPINELESS CACTI OF THE FRUIT-GROWING VARIETIES.

When I first visited California I was a good deal interested in the beekeepers' ranches. At that time the proprietors of most of them were single men. I was especially pleased and attracted by the beautiful home of G. B. Woodberry, of Glendale, near Los Angeles. Some of our older friends may remember that about that time I was particularly vehement about urging these bachelor beekeepers to have a wife, at least when they were, say, 25 years old or more. Well, the next time I visited that pretty little home I found a wife there. Of course I do not know how much my advice had to do with it; and with this preface I want you to read the nice letter below.

Mr. Root:—I read with interest your remarks concerning the spineless cactus some time ago, and I am sending you by parcel post a cutting from the variety called the Malta. It may grow in Ohio during the summer, and it can be taken up and carried to Florida in the fall if you wish to try it there. I also send some of the literature of five years' ago concerning the subject.

I find it makes a good hedge-plant, and, with garden culture, a remarkable growth. Without care, however, the results are very much less—at least with this variety.

I had one plant in the garden that set over 200 new slabs the third year while a similar plant on the ranch, without water, set only a few.

I am told by the Los Angeles branch of the A. I. Root Co. that you and Mrs. Root expect to be in California this summer. You will, no doubt, remember me and the strawberries which you picked at my place in the winter when you visited me over twenty years ago. I was a bachelor then; but now I have a daughter who graduates from college this spring. I still have the ranch, a "mess" of bees, and shall expect a call from you and Mrs. R. when you visit Los Angeles. The Glendale cars run to within 200 feet of our home in Glendale.

Glendale, Cal., April 10. G. B. WOODBERRY.

Before this letter came I had been longing for a sight of my cacti growing in Florida; and I had really thought of trying a leaf in my Medina garden, even if it should cost me a dollar or more. Imagine, then, my happy surprise on receiving a leaf 19 inches long, 8 inches wide, and weighing $4\frac{1}{2}$ lbs., and so smooth and free from spines that you might give it to the baby to play with. The variety is what is called the Malta. Below is a description of it:

MALTA.

A good, hardy, rapid grower; leaves, medium size, 18 inches long by 8 wide; very few short, weak, hair-like spines; bristles almost wholly absent; fruit nearly 4 inches long by 2 in diameter; skin yellow, turning to light red when fully ripe; flesh, salmon, with crimson shadings; seeds small; bears abundantly even when quite young. A most desirable variety.

What do you think, friends, of a cactus

fruit 4 inches long and 2 inches in diameter, and more luscious than an orange? By the way, perhaps I should say that Ernest says he tasted of the fruit during his recent trip in California, but did not like it very well.

I am sure our good friends will excuse me if I digress enough here to say that Mr. Howard R. Calvert, my next oldest grandson, was married June 29 to a young lady he met in California—a daughter of Mrs. H. G. Aeklin, who for many years had charge of our St. Paul agency. Howard and his bride started immediately after the ceremony for their home in San Francisco, and I shall now be able to get accurate information in regard to spineless cacti, both fruit and fodder, from California as well as Florida.

You will notice that friend Woodberry agrees with the statement made by the Department of Agriculture on page 515, June 15, in regard to growing plants under culture compared with letting them grow wild. Before I got this information I had pretty well satisfied myself, from the way my plants grow in Florida, that, like all other vegetation, it would respond to thorough culture and fertilization.

As there has been some contradictory information in regard to planting, I copy the following from one of Burbank's circulars.

SPECIAL DIRECTIONS FOR SUMMER PLANTING OF THE BURBANK CACTUS.

1. Dry plant for a day or two in the shade.
2. Plant cutting in the ground to the depth of one-half.
3. If the ground is moist, pack the earth about the cutting firmly, and water after a few days. If the ground is dry, water on planting.
4. Shield the cutting from the direct rays of the sun until rooted to prevent sunburn.
5. Do not water too much. Never keep the soil soggy.

SPINELESS CACTUS AND THE FLORIDA GROWER, ETC.

In our issue for June 15 I published some of the claims of Samuel C. Kidder in regard to the spineless cactus. Well, our friend Kidder has been in the habit of carrying an advertisement for some time back in the *Florida Grower*. It seems that the *Grower* considers his claims almost too extravagant, and, as a consequence, Kidder's advertisement has been recently changed so as to read as below:

SPINELESS CACTUS.—Certain varieties are very valuable, notwithstanding some professional opinions and chemical analysis. This paper refuses to publish evidence in its favor from a reliable resident grower. Send stamp for catalog of varieties that are right. SAMUEL C. KIDDER, Monticello, Florida.

I congratulate the *Grower* on keeping an editorial eye on its advertising pages as well as on the reading-matter. Mr. Kidder now must shoulder the responsibility, and it is up to him to give us unbiased proof of what he claims as possible with the new creation in the way of spineless cactus.

SPINELESS CACTUS—BURBANK, AND THE OTHER KIND, ETC.

Mr. A. I. Root:—Your notes on spineless cactus interest me very much, especially the *ignorance* most writers display in regard to it. They seem to name all spineless cactus "Burbank." Now, Mr. Burbank has originated (or claims to have originated) several varieties of cactus that make an enormous growth of slabs and fruit at *Santa Rosa, Cal.*, where they have rich adobe land and an annual rainfall of about 25 inches; but the same varieties of cactus hardly grow at all here in Fresno Co. with or without irrigation; but the government cactus (or, rather, the cactus imported by the United States and propagated at Chico, Cal., and distributed free) grows here very nicely, and I have growing on very poor land about 2500 slabs. I was at Santa Rosa at Mr. Burbank's place, and saw a growth of 200 tons per acre (not a whole acre), and I saw the fruitage of 90 tons per acre (not a whole acre).

I strongly suspect that Mr. Burbank highly fertilized the *already* rich land. In fact, I saw white powder on the ground, and it was not alkali either. I have spent considerable time and probably \$50 in money investigating and buying spineless cactus. Many varieties are worthless. Some varieties are valuable only for fruit, which carries a high percentage of sugar, and other varieties produce slabs at a great rate. It has about the feeding value of pie-melon, and stock will live over famine times on cactus; and since it can be grown and allowed to accumulate from year to year on the land until 1000 tons or more has accumulated on the acre, it is reasonable to figure that when famine or dry years come along, as they have done and will do again, the cactus will be valuable to save the stock from starving to death, as they often do in the West and Southwest. I have seen the chickens peck the slabs all to pieces when green feed was scarce.

I have seen plants produce here in Fresno Co., at Mr. J. C. McCubbin's of Reedley, Cal., at the rate of 114 tons of slabs per acre (Chico or United States varieties). I think it is worth \$1.00 per ton as a dry-year feed-over ration; and 1000 tons can be accumulated on an acre in five years with very

little labor, irrigation, or care, and will need replanting about once in fifty years. The land gets richer and richer where cactus grows. Thus, it seems to me to have some real value. The Miller & Luz Co. planted 80,000 slabs for this very purpose. The cactus at Mr. McCubbin's was not irrigated nor sub-irrigated, and the rainfall was 11 inches. Poor land will grow cactus; but rich loam grows better, and yields better cacti. I have read and studied all the literature to be found in the library of the University of California on the subject, and I have seen it growing under all conditions I could find, and am experimenting with it, and still hope to find it of value. I can tell you a great deal more about cactus if it is interesting to you.

Selma, Cal., June 27.

O. S. DAVIS.

We are very thankful to get the above information right from headquarters, or, rather, from near where Burbank brought about his wonderful results. It seems to me that a dollar a ton is a rather low price for cow feed compared with timothy hay and alfalfa—say from \$15 to \$25 a ton. On page 515, June 15, I copy from a government bulletin the statement that an acre of prickly pear is worth more than six times the value of sorghum for feeding purposes. According to this a ton of sorghum is not of very much value, say just as it is cut for cattle feed. It seems to me there is a discrepancy there somewhere. Also notice what friend Borchers says about these for feed on page 557, July 1. I am also pleased to note from the above that the chickens will take it as green feed. I am sure this is going to be quite an item in its favor in Florida.

Later.—To-day is July 26; and the cactus mentioned above, planted about July 1, has now eight little slabs started (one almost as large as my hand) and it is growing rapidly every day. I expect to give you some pictures of it, illustrating how rapidly this spineless cactus grows when it once gets a start.

TEMPERANCE

A LETTER FROM THE GOVERNOR OF KANSAS
HIMSELF IN REGARD TO PROHIBITION
IN THAT STATE.

No doubt our readers have been pained to see statements in our daily papers to the effect that Kansas is "Hard up" financially, etc., in consequence of their "puritanic prohibition law." Before submitting to our readers the positive statement of the governor himself, we give below a letter from our untiring and indefatigable prohibition friend Minnie J. Ellet:

East Akron, Ohio, July 22, 1915.

My Dear Brother Root:

A few weeks ago one of the liquor-license commissioners of this county told me that the governor of Kansas had said that all his state could do to save herself was to go back to license and regulation. I told him one of us was grossly misinformed in regard to Gov. Capper's attitude, and that that week's *Union Signal* had a splendid article, excerpts from the governor's speech before Kansas bankers. I told our commissioner that, and he set it down as "misquotation of a temperance paper that always makes things too big." I wrote to Gov. Capper that night, and on another sheet I'm sending you the exact copy of that letter.

Yours for God's glory through the highest good of all for whom he died.

MINNIE J. ELLET.

Below is the letter referred to, from Governor Capper, of Kansas:

STATE OF KANSAS
ARTHUR CAPPER, GOVERNOR.

Topeka, June 24, 1915.

Dear Miss Elliot:—I have your letter of June 22 and note the statement that Mr. C— attributes to me. Neither Mr. C— nor any one else ever heard me say that "prohibition is a failure wherever tried," or any other statement of a similar nature. But I have said, and am glad to repeat here, that I think one of the greatest blessings ever bestowed upon this state, and the law which is doing more to make good men and women, and to bring prosperity and happiness to the people of Kansas, is the amendment to the constitution, prohibiting the traffic in intoxicating liquors.

Kansas has had prohibition for about thirty years, and it may be truthfully said that the law was never so well enforced as now, and never so generally approved by our people. Approval, indeed, is too mild a word with which to express the attitude of Kansas people toward this provision of the state constitution. Most of them are enthusiastically in favor of it. It is the portion of the fundamental law of the state that is nearest their hearts.

I am returning the clipping from the *Union Signal*. I am correctly quoted in that article.

I am emphatically and enthusiastically in favor of national prohibition, and am always glad to do anything I can to hasten the day when there will not be a saloon in this or any other country.

With best regards, I am

Very respectfully,

ARTHUR CAPPER.

THE "ACHAN" OF THE LIQUOR-TRAFFIC.

Some of the friends thought, no doubt, I was rash in suggesting in Our Homes for June 1 that God permitted this great war, with its awful loss of life and property, because the United States and other nations persisted in *cherishing* the liquor-traffic for the revenue, etc., it furnished. With this matter in view it is a little refreshing to find the clipping below, which I take from the Chicago *Farming Business*.

BREAD OR BOOZE.

Great Britain uses more grain in the manufacture of alcoholic liquor in one year than she produces in her own territory in the same length of time; so that, in effect, her people are not working their farms for the purpose of making bread with which to feed themselves and their fellow-citizens. Rather, they are working them for the express purpose of manufacturing booze with which to destroy the economic efficiency of themselves and their fellow-citizens. The whole country is dependent on its imports for its bread.

We cannot conceive of any poorer business than this, that a nation should use all the grain which it produces in the manufacture of liquids which sap the vitality and efficiency of its people without adding to any one desirable or useful quality, thus leaving the nation dependent upon the outside world for its bread and cereal foods. Such a practice is a fundamental economic error, and it seems to have taken this great war to teach Great Britain the folly of such a method.

The great war of the past nine months has taught the nations of the earth, as no moral wave or religious campaign ever could have taught them, the absolute uselessness of alcoholic beverages. It is not a moral lesson which is being taught so much as

it is an economic lesson. And out of this war will come the greatest good which ever yet has been done to the cause of temperance and of personal and national efficiency, for it will have taught very forcefully the individual and national damage which comes from diverting the grains of the world to the manufacture of harmful drinks rather than using them for the manufacture of bread and other foods.

When I wrote that Home paper I was not aware that Great Britain used practically every bit of grain she raised for making booze; and I was not aware, either, that Great Britain was getting toward the point of starvation. See recent dailies in regard to the way the "high cost of living" has gone up in London. It rejoices my heart to see the way in which our agricultural and farming papers are standing up for prohibition. It is a terrible punishment we have been receiving, I admit; but I am firmly convinced that out of this great war will come one of the greatest benefits to humanity. I wish the clipping above might be copied and sent broadcast over all the earth. May God be praised that we have at least one farm paper and one farm editor who has enough breadth of character to look ahead and recognize the lessons God has been striving to teach the whole wide world.

GOD'S KINGDOM COMING; MORE EVIDENCES OF IT.

We clip the two following items from *Farming Business*, of Chicago:

BOOZE OFF THE BOARDS.

The Associated Bill Posters and Distributors of the United States and Canada will not take any booze advertising the coming year, according to a promise by Donald Ross, testifying before Judge Landis in Chicago for the bill posters.

ARREST HOTEL-KEEPERS.

Chicago hotel owners and managers will have to bow to the law soon, according to statements of the anti-saloon leaders. Managers of the Sherman, Fort Dearborn, and La Salle have been arrested for selling liquor on Sunday.

And here is something from the *Cleveland Plain Dealer* of July 1:

ALABAMA BEGINS GRAPEJUICE DIET.

BIRMINGHAM, Ala., June 30.—After trying prohibition four years and then limited saloons four years, this state again becomes totally dry on the stroke of midnight to-night.

Although extra police precautions were taken to prevent any disorder at the wake of the liquor business, the officers had little to do during the early part of the day.

The law which makes Alabama totally dry was passed about six months ago by the legislature, and allowed the liquor men until to-night to get their affairs in shape and go out of business.

Along with this law measures also were passed prohibiting the advertising of liquor within the state and making it unlawful for express or railroad companies to accept shipments to firms or individuals in excess of two quarts every thirty days.

These bills were designed to prevent the state being flooded with literature and wet goods by mail-order houses outside the jurisdiction of Alabama courts. Both measures have been upheld by the courts.

"GOD'S KINGDOM COMING."

Some years ago, while up in Puget Sound, Washington, my good friend H. A. March gave me a little experience of a wet-and-dry fight they had in their own county. After having a fierce battle the wets won out by a narrow margin, and a saloon was opened up not far from Mr. March's home; but, to the great astonishment of everybody, it did not pay expenses. In fact, it starved out in just a few months. Public opinion had got ahead of the law in spite of the trickery and cheat of the wet side. There was nobody to buy the drink after they had won the battle, as they supposed. Well, I have been watching for this very thing. With the advance the world is making, it would be strange indeed if public opinion did not starve out some of the saloons after paying \$1000 or more license.

Below is a clipping from the *Union Signal*:

100 MILWAUKEE SALOON KEEPER TO ABANDON BUSINESS.

It is reported by the Philadelphia *North American* that more than 100 saloonkeepers are to go out of business on July 1. This information is said to be contained in the annual report concerning saloons sent to the city council.

Just now I read in the *American Issue* that the Board of Health of the great city of New York has decided "It is as necessary to fight drink as it is to fight an epidemic." Does not that sound sensible, even if it has taken years to find it out and arrive at such a conclusion? *God's kingdom is coming.*

THE FOOT AND MOUTH DISEASE NOT THE WORST "MOUTH DISEASE" AFTER ALL, ETC.

The following is clipped from *The Day*, of New London, Ct.:

Can any argument prove that the one deep need of New London is not an ocean terminal, but a termination of the power that turns men into bleary-eyed soaks, as Billy Sunday puts it? It is not a college for training the minds of our daughters how to think correctly, but a civic conscience that will safeguard the homes of the men our daughters will marry.

It is stated that the hoof and mouth disease broke out among cattle fed on the slop and refuse of distilleries. But one has only to listen to the vile language of rum-filled men, and he can trace the origin of a worse "mouth disease" than that of an ox. Billy Sunday says that "alcohol will remove the stains from summer clothing. One has only to walk around the rum-cursed sections of New London to see that alcohol will also remove the clothing as well as the stains. Visit the pawn-brokers' shops, and you will see that alcohol can remove a ring from a woman's finger, a watch from her husband's pocket, tools from the workman's chest, and, worst of all, clothing from the children's backs."

I appeal to the manhood of this beautiful city to rise in their true strength and move this remover of the best things we have in our homes. The saloonist insists that the liquor business is "good for business." But he cannot prove that it is good for any business under the sun but that of the undertaker.

REV. FRANCIS ADAMS.

RETURNING THE EMPTIES.

Collier's Weekly says:

Rev. E. M. EVANS, of the Trinity Methodist Church, Des Moines, Iowa, got one of those circular letters booming "Old Bob Adams' whisky." He printed a reply in the Des Moines *Register and Leader*, that should interest every intelligent man whose talents are being misused in the booze business:

"I note you pay the freight on returned empties. I should like to send you a full carload of empties if you will honor your agreement. I suppose the freight will be much cheaper on full carload lots. To be honest with you, the empties are not in first class condition. They consist of empty men—empty of manhood, energy, ambition, prospects, self-respect, and necessities of life—empty head, empty heart, empty soul, empty stomach; also empty women, empty of womanhood, refinement, modesty, and hope. Will it be worth while making the return of this carload of empties? Will this carload of empties be worth the freight to you?"

Do you haul back your empties, Mr. Respectable Distiller, or are you dumping the junk of them on the jail and the poorhouse?

CINCINNATI, AND WHAT THE CITY IS DOING TO KEEP UP THE OHIO PENITENTIARY.

We clip the following from the *American Issue* for July 23:

Mr. E. A. Mack, Cincinnati, Ohio—

My dear Sir:—I am the matron of the woman's department of the Ohio Penitentiary, and I desire to say there are more prisoners from Hamilton County in the woman's department at this time than from any other county in the state. One-fifth of our population are from Hamilton County, and at least 85 per cent of the prisoners in the institution are here from drink. Sincerely,

CORA E. WELLS, Matron Ohio Penitentiary.

THE FLYING-MACHINE—A NEW USE FOR IT.

When I was having such an enjoyable time in being with the Wrights when they made their first experiments, my enjoyment was greatly marred on being informed by Wilbur Wright that the flying machine would probably be of more use in war than as a vehicle to assist commerce and travel; and it has saddened my heart again and again to see this prediction fulfilled before my eyes. Well, just now I find the following clipping in *Farming Business*.

HUNT FIRES IN AEROPLANE.

Jack Vilas has received an appointment as forest ranger, and will range the north woods of Wisconsin in his hydro-aeroplane instead of sitting on top of a 90-foot tower and looking at a limited range of country. By using his machine he can rise to such heights as to discover a fire 50 miles away, and quickly fly to the scene and report for re-enforcements if needed.

From the above it seems that this same flying-machine is destined to do great work in preventing forest fires from getting such a start as to destroy miles of timber, and sometimes almost whole towns and villages. May God hasten the time when the flying-machine will prove to be an aid to peace instead of an aid to war.

POULTRY DEPARTMENT

"SWAT THE ROOSTER," AND THEREBY SAVE
\$15,000,000 A YEAR.

The Department of Agriculture has just sent out a beautiful placard. At the top of the sheet we read:

"PRODUCE INFERTILE EGGS."

This placard contains eleven pictures of eggs that have been under a hen or in an incubator for different periods of time. As we cannot give the cuts we give the reading under them.

No. 1.—Fertile egg after 24 hours at 103 F.; fertile germ beginning to hatch; not perfect for food.

No. 2.—Fertile egg after 36 hours at 103 F.; blood ring formed; not good for food.

No. 3.—Fertile egg after 48 hours at 103 F.; blood ring not fully developed; unfit for market; will be thrown out by candler.

No. 4.—Fertile egg after 72 hours at 103 F.; blood-vessels of embryo chick clearly marked.

No. 5.—Fertile egg after 7 days at 103 F.; compare with infertile and fresh egg.

1A.—Infertile egg after 24 hours at 103 F.; no fertile germ; no blood ring; still good food; it would be still better if kept cool.

2A.—Infertile egg after 36 hours at 103 F.; compare with fertile egg under the same conditions.

3A.—Infertile egg after 48 hours at 103 F.; still good food.

4A.—Infertile egg after 72 hours at 103 F.; not an absolutely fresh egg, but useful in cookery.

5A.—Infertile egg after 7 days at 103 F.; still usable for food. It would be a perfect egg if it had been kept cool. Compare with fresh egg and fertile egg.

In the middle of the sheet occurs the following alarming information; and it certainly ought to be alarming to every farmer and poultry-keeper.

FERTILE EGGS COST THE FARMER \$15,000,000 A YEAR

Farmers lose \$45,000,000 annually from bad methods of producing and handling eggs. One-third of this loss is preventable, because it is due to the partial hatching of fertile eggs which have been allowed to become warm enough to begin to incubate.

The rooster makes the egg fertile.

The fertile egg makes the blood ring.

You can save the \$15,000,000 now lost from blood rings by keeping the male bird from your flock after the hatching season is over.

The rooster does not help the hens to lay. He merely fertilizes the germ of the egg. The fertile germ in hot weather quickly becomes a blood ring, which spoils the egg for food and market. Summer heat has the same effect on fertile eggs as the hen or incubator.

INFERTILE EGGS WILL NOT BECOME BLOOD RINGS.

After the hatching season cook, sell, or pen your rooster. Your hens not running with a male bird will produce infertile eggs—quality eggs that keep best and market best.

RULES FOR HANDLING EGGS ON THE FARM.

Heat is the great enemy of eggs, both fertile and infertile. Farmers are urged to follow these simple rules, which cost nothing but time and thought, and will add dollars to the poultry-yard returns:

1. Keep the nests clean; provide one nest for every four hens.

2. Gather the eggs twice daily.

3. Keep the eggs in a cool dry room or cellar.

4. Market the eggs at least twice a week.

5. Sell, kill, or confine all male birds as soon as the hatching season is over.

NOTICE.

Valuable published information on the raising and care of poultry and eggs, and individual advice on these subjects may be obtained by writing to the Bureau of Animal Industry, U. S. Department of Agriculture, Washington, D. C.

A. D. MELVIN, Chief, Bureau of Animal Industry.

Approved:

D. F. HOUSTON, Secretary of Agriculture.

In addition to the above, *Poultry Life* in an article on the subject says a fertile egg will begin to germinate at a temperature of 90 degrees. If this is true, an egg that has been exposed to a temperature of 90 degrees down in Florida, here in Ohio, or anywhere else, for 24 hours, would become a rotten egg if kept long enough at a moderately warm temperature; and this same authority says, also, that an infertile egg may be under a sitting hen or in an incubator 21 days or more, and still be fit to eat.

Perhaps now I might mention something that I should otherwise have been a little backward about telling. Eggs that do not hatch, either under the hen or in an incubator, I boil and feed to the chickens; and I have never yet seen any bad effects from feeding boiled eggs that had been 21 days in an incubator. If the germ was started, of course the chicks will have "boiled chicken;" and the way they fight for it I have thought sometimes it might start cannibalism.

Well, in cutting open an infertile egg it looks so much like a good egg boiled that I have several times tasted of the yolk, but could find nothing unpleasant about it. In fact, this same poultry journal I have mentioned says that an infertile egg will stand a temperature of 103 for 21 days and still be fit for food.

Now, the above emphasizes particularly the fact that a hen should never under any circumstances be allowed to sit on eggs all night long. If you wish to get a reputation for good eggs, gather them every day sure, and twice a day is better. If the hen steals her nest, use the eggs in your own home. Second, find some place to store your eggs until they are ready to go to market where it is at least moderately cool. Do not leave them an hour in the sun in a warm room, and certainly not anywhere near a hot stove. If you have no cool cellar, and would like to keep your eggs several days, put them in a pail and hang them in the well, as we used to keep the butter in hot weather in the good old times.

Gleanings in Bee Culture

Sweet Clover Growing Along an Irrigating Ditch

Southern Headquarters for Italian Queens

Photo of W. D. Achord of Fitzpatrick, Ala., with helpers, also his queen-rearing yard. Queen-house and residence in background. With six experienced men, and 600 mating-boxes, also 700 full colonies of pure Italian bees, we are able to give good queens and prompt service. Untested queens, 1 to 11, 50 cts. each; 12 and more, 45 cts. each. Tested, \$1.00 each. No disease. Pure mating and safe delivery I guarantee.

Questions and Answers

Relating to Modern

Automobile Design, Construction and Repair

By Victor W. Page, M. E.

Author of "The Modern Gasoline Automobile," "The Modern Gas Tractor," etc.

Price \$1.50. A Self-educator on Automobiling without an Equal.

5¼x7½ Inches; 622 Pages; 329 Illustrations and Plates

This practical treatise consists of a series of thirty-six lessons, covering—with nearly 2000 questions and their answers—the automobile, its construction, operation, and repair. The subject matter is absolutely correct, and explained in simple language.

A popular work at a popular price.

Answers every question you may ask relating to the modern automobile.

Copy of this book sent prepaid to any address on receipt of price.

EDITORIALS

THE A. I. Root Co. has been awarded the grand prize and also a gold medal by the California-Panama Exposition at San Diego for its general exhibit of beekeepers' supplies and honey. We consider this the best exhibit we ever made.

BEEKEEPERS who are neglecting the information sent out by governmental agencies are missing much of value.

An excellent contribution to the stream of information from such sources is a series by Morley Pettit published by the Ontario Department of Agriculture, Toronto. Two of the latest of these are, "Bee Diseases in Ontario," and "Natural Swarming of Bees and how to Prevent it." These pamphlets are characterized by readable language, concise directions, pertinent illustrations and good printing. The manuals are free to residents of Ontario.

Twenty Years a Bee Inspector

THE oldest foul-brood inspector, or, more exactly speaking, the one who has been longest on the job continuously, is N. E. France, of Platteville, Wis. On the 11th of August he began his 21st year. New laws just passed will give him a wider scope. These long years of continuous service speak volumes for Mr. France's faithful discharge of duty.

This same Mr. France was also General Manager of the National Beekeepers' Association for a good many years, or, up to the time of its reorganization some two or three years ago, when it was placed on the basis of direct affiliation with state or other beekeepers' societies that desired to be connected with the parent body.

Honey-crop Conditions and Prices

THERE is not much to add to our general summary in our last issue, page 608, except to say that conditions are getting better in New York, and some beekeepers in that state will secure a good crop. Conditions

in eastern Colorado show a total or partial failure. As this is an important part of the alfalfa district of the West, the shortage there may stiffen prices on alfalfa honey; but so far scattering reports show that in other portions of the Rocky Mountain districts there will probably be the usual crop of alfalfa, so that the shortage in eastern Colorado may not make much difference.

There has been an average crop in Ontario, Canada—about 55 lbs. per colony, according to the Crop Report Committee of the Ontario Beekeepers' Association.

Wisconsin and Minnesota will not come up to the yield of last year, either in comb or extracted honey. In fact, many predict that it will be only half a crop. To offset this, conditions are improving in New York and Pennsylvania.

In Ohio, conditions are widely different. In the northern part of the state, and especially the northwestern part, there will be a fair yield of clover honey. In some of the other portions of the state there will be almost a total failure.

The Weather Bureau map shows that general rains have been almost universal over the north-central portions of the United States. Some needed rains have been coming in Florida and Texas. Conditions are improving slightly in northern Texas.

So far comb honey is ruling at about the same price as last year. Extracted honey is running fully one cent lower.

Live-bee Demonstrations, Once More ; One Important Point ; Advertising Honey

In our editorial caution, page 610, last issue, we merely alluded to one important point when we should have said more on it, and that was, that the same bees should not be used more than twice in succession in bee-handling stunts. Ordinarily any bunch of bees, if properly manipulated, can be used in these demonstrations; but if the operation is undertaken more than once with the same bees they may cause trouble. If it is repeated four or five times in suc-

cession they may sting severely. When they are first rolled in a dishpan they are demoralized, and have no thought of stinging. It is an entirely new experience, and they are taken by surprise. They then can be handled like a bunch of kittens. But when the operation is repeated one time after another, they become less and less demoralized until they regain their complete colony spirit—the spirit of offensive and defensive. Then look out or *you* may be the one to be surprised.

Operators at county and state fairs make the mistake of handling the same bees over and over until they resist and resent all attempts to “make them good.”

There will be a number of live-bee demonstrations, doubtless, this fall. As we have done more of this work, perhaps, than any one else, we wish to emphasize several points:

1. Use gentle bees to start with, and those having a queen. While this is not strictly essential, it is advisable.

2. Do not use the same bees more than twice in succession. This is *very important*.

3. Always use smoke. Do not handle the bees roughly, much less pinch or crush them. We never do. Handle them as carefully as you would your day-old baby chicks. A bruised or maimed bee may stir up the whole bunch. If only one bee stings, the smell of the poison incites the rest.

4. All movements must be very deliberate. *Take a full minute* to pick up a handful of bees. It is impossible to grab a handful of bees as you would a handful of beans. The slambang methods of a vaudeville performer will not work.

Live-bee handling at fairs or other public places means more than merely satisfying idle curiosity. Besides its educational value it is one of the most potent means of advertising honey that there is known. It draws crowds as nothing else will, and a skillful manipulator will whet the appetites of his audience for honey. One purchase of a bottle or a section of honey will mean the sale of more. It is important that the live-bee demonstrator do his work right.

The Federal Net-weight Law, and its Practical Operation after a Year of Trial; How to Avoid Getting Stung by Uncle Sam

A YEAR ago we had a good deal to say about the federal net-weight law—particularly in regard to its application to comb honey. There has been a good deal of grumbling, because many believe that its practical operation is unfair to the produc-

er in that it compels him to eliminate the weight of the section itself from the comb honey it contains, and because it gives to the consumer as much as or more than the weight calls for on the minimum net-weight basis. But the principal complaint has been that it makes a lot of work and worry, some saying they have quit the production of comb honey, as they will not put up with these seemingly impossible conditions. As a matter of fact, many small comb-honey producers are paying no attention to it. As long as comb honey does not cross a state line the producer is safe, providing also the state in which the honey is produced has no net-weight law.

Most of the complaints relative to the law are made through ignorance of its actual provisions; and if the producer will only take time to look into the matter and then comply with the law he will find it entails no great hardship after all. When we get ourselves once adjusted to it it will result in better comb honey going to the public. The law practically compels every producer to use separators or fences and to grade his honey according to its weight. Before the law went into effect, practically none of the comb honey was properly graded. The sections (the fat and the lean ones) were mixed in an indiscriminate way in shipping-cases. The federal law, as well as many of the state laws that have been passed to conform to it, have stopped this because it is very unsafe to put out comb honey without properly grading it. While the law does not specify how comb honey shall be graded, it does say that every box must either be marked its exact net weight or the minimum net weight. As it is practically impossible to mark every section its exact weight in ounces and fractions of ounces, the only thing that is at all feasible is to grade the sections in groups according to their minimum net weights.

A few sections during a good season run around 13 ounces, exclusive of the section itself; but the great bulk of comb honey in an average season will run a minimum of 12 ounces. A large number will run a minimum of 11 ounces, and only a few 10 ounces. It is customary, therefore, to have some small spring scales and grade the sections into three groups by weight. Where there is very much honey that runs 13 ounces or more, one more grade will be provided. Each group is then cased by itself. After the sections are all in the shipping-cases, and before the covers are put on, a rubber stamp showing, say, “12 ounces net” is used to mark each section in that group. With pad in hand, strike the

pad, then the section; then the pad, and then the section. The work can be done very rapidly, and after the 12-ounce group is all marked, another rubber stamp, indicating 11 ounces net, is used, and so on to the 10-ounce stamp. In this way every section can be marked its minimum weight with a very little labor. The cases of sections are then sold by their minimum net weights. A case of 12-ounce sections should be sold for more than one holding 11 ounces.

When comb honey is properly graded in this way by weight it will usually bring more money than comb honey ungraded; and we venture to say that the beekeeper is not going to lose very much if he grades his honey as he should, and then charges a price that the market will command for such honey.

The buyers will pay more for such honey because, under the practical operation of the federal law, they know exactly the kind of honey they are paying for. Under the old *regime* it was impossible to know how the sections averaged by weight, although they could know what the gross weight was on the whole caseful of sections; but this encouraged indiscriminate mixing of the heavy bulging sections with the lean ones.

Rubber stamps carrying the various net weights generally used, as well as suitable scales, can be purchased of the dealers at a reasonable price; and no one should neglect the precaution of keeping from getting into trouble with Uncle Sam or the state. It is well to bear in mind that in some states there are in force net-weight laws. A year ago our dear uncle winked at a good many things that he will not now tolerate; and we desire to caution all comb-honey producers to be on their guard how they ship their honey.

Of course extracted honey in glass and tin come under the operation of the same laws; but in the case of the liquid product, each package can be filled to its exact weight or the weight specified on the label, which *must* show. Moreover, if the package weighs 36 ounces the label must show 2 lbs. and 4 ounces—not 36 ounces. Anything under a pound must show in ounces; anything over a pound must show in so many pounds and so many ounces if more than even pounds.

The Ohio Field-day Meet

THE Ohio field-day meet, which was held at the apiaries of Fred Leininger & Son and Mr. J. H. Allemier, Delphos, Ohio, August 4, was a complete success. Practically un-

heralded—that is, not advertised in advance—there was a good attendance—something over sixty beekeepers being present. A careful estimate was made by the state inspectors as to the number of colonies represented. Several guesses were made, but a little computation showed at least 10,000 colonies were represented, with the probability of 15,000. The season, though late, had been from fair to good, and was still in full blast in that section of the state, and, as a natural result, the beekeepers from all over northwestern Ohio came to the meet. The most of them had secured some honey, and practically all of them were in localities where more honey was in sight. In going up by train and trolley we noticed that the nearer we got to Delphos, Ohio, the more white and sweet clover were in evidence.

There were several beekeepers there who had over 400 colonies each; two or three had over 500, and a large number had 100. The season has been backward, cold, and rainy; and at a time when clover is usually in its prime the plants were held back. It was also a noticeable fact, as we looked out of the car windows, that there were certain localities where not a single head of clover could be seen in the pastures; but when we got into Allen County we began to see a decided change for the better. In fact, it seemed to be the center of a group of beekeeping territories. Ohio has never been noted for being a great honey state as compared with New York, Michigan, and Wisconsin; but if there is any portion of the state that seems to have a large number of bees and beekeepers it is the northwestern part. The inspectors thought the lack of clover in some portions of the state was due to lack of lime in the soil.

At all events, for 1915 Allen County seemed to be an ideal place for a field meet; bees worked well all day. It looked like rain, but none fell until the beekeepers began to disperse.

Through some misunderstanding or mistake no preliminary announcement of this field meet, except too late, appeared in *GLEANINGS* or any other bee journal. The secretary, and Mr. E. R. King, sent out postal-card announcements that brought out a good crowd.

The day and place of meeting were ideally perfect. Fred Leininger & Son and Mr. Allemier have as pretty apiaries as one can find in the state. Their bees are what we would call light leather-colored gentle Italians; and by the number of supers on the hives we would say they were hustlers. We doubt if there is another apiary in the United States that has a more uniform strain of

bees than the Leiningers have. They are queen-breeders as well as honey-producers, and as such have been making a specialty of a fine strain of gentle honey-gatherers that are uniformly marked. The bees of every colony were so near alike in their yards that it would be practically impossible to distinguish one from the other. Yes, we did find just one with different bees in the yard of Mr. Allemier, the father-in-law of Mr. Leininger. This happened to be a pick-up swarm.

The apiaries where we met were models—everything so neat, grass kept down, hives in perfect rows, and in groups of two, threes, and fours. The hives were home-made, but as perfect as a factory product, because Mr. Leininger is a fine mechanic.

We wondered if this slicked-up appearance was a common every-day affair, or only special for this field day meet. Mr. Morris and Mr. Ames, bee-inspectors, said they had been at these yards at different times unannounced, but they had never been on the premises when there was not perfect neatness and orderly arrangement. We observed that Mr. Leininger had been breeding, not for bright yellow color, but for uniform color, three yellow bands, gentleness, and good honey-gathering qualities. He has surely secured a perfect combination. The bunch of beekeepers walked all through the yards, sitting on the hives, getting in front of the entrances, and, notwithstanding the bees were flying well that day, not a person was stung, except when Mr. Morris, one of the state inspectors, gave a live-bee demonstration. He went at them with a vengeance—poured the bees all over himself, put handfuls of them in his mouth, and then blew them on the girls. He was not stung in the mouth, but was stung once or twice on his bare arms and hands. If the Leininger strain had not been as gentle as it was, he might have come to grief; but he said he knew the bees.

We have secured a beautiful photograph of this field-day group of beekeepers, and we hope to present it to our readers in our next issue. If the meet had been advertised in several issues in advance, the attendance, doubtless, would have been very much larger.

The meet closed by a ringing resolution commending the good work done by State Bee Inspector Shaw and his deputies in treating and eradicating foul brood in Ohio. This was passed unanimously. Another resolution of thanks was put through with a shout, expressing the thanks of the beekeepers for the courtesy shown them by the Leiningers and by Mr. Allemier.

In Memoriam of Mrs. H. G. Acklin

IN our issue for June 15, page 477, we spoke of the sudden death of Mrs. H. G. Acklin, a lady well known to the beekeeping interests of Wisconsin, Minnesota, southern California, and later of central California. She was a native of New York, but removed with her parents to Wisconsin where she fitted herself for teaching, and later on taught for several years; but the honeybee had always been an object of interest to her, and she fully resolved to take up bees when opportunity offered, and it came. In 1884 she went to St. Paul, Minn., where she met Mr. J. C. Acklin. In 1885 they were married. Fortunately some bees were on the lot where they were building a home, and thus began their experience with bees.

Early in 1893 they began handling beekeepers' supplies, and for fifteen years were prominently connected with the bee business and in the rearing of queen-bees. Mr. Acklin devoted himself to the supply business while Mrs. Acklin gave her attention to the bees and to the rearing of queens. She took a very active part in the bee conventions, for her enthusiasm knew no bounds.

MRS. H. G. ACKLIN

On page 870, 1906, we recorded the fact of Mr. Acklin's sudden death, leaving Mrs. Acklin with health not good, and a little daughter, Ethel. Mrs. Acklin continued in the business for a couple of years; but ill health compelled her to make a change of climate and also a change of occupation. In 1908 she went to California, where she bought an orange grove in Glendora, about 25 miles from Los Angeles. In the meantime she did not wholly lose her interest in bees. She kept a few and attended the bee

conventions, and edited the California department in GLEANINGS; and when the A. I. Root Co. established a branch office in San Francisco she was given charge of it by our Mr. Boyden, who established it. She continued as manager up to the time of her death, which occurred May 30, 1915.

It was our privilege to visit Mrs. Acklin in her home at Oakland in our recent trip to California. We came to know more and more of her sterling worth, not only as a business woman and manager of our branch office at San Francisco, but as a careful mother of an attractive daughter of refinement and education, and a beekeeper of considerable experience. In fact, we doubt if there is another young woman in the country who knows the theory and practice of the keeping of bees better than Ethel Acklin, or, to speak more exactly, Mrs. Ethel Calvert.

Perhaps at this point it might not be inappropriate to speak of a little romance that ended very happily. Howard R. Calvert, son of J. T. Calvert, treasurer of the A. I. Root Co., last winter was looking after the A. I. Root Company's exhibits, both at San Diego and also at San Francisco expositions. It was during one of the visits to the latter city that he became acquainted with Miss Acklin. This was some time before the death of her mother. Howard showed a wonderful adaptability in the matter of helping Ethel to wash dishes. He said he used to help his mother in the same way, but we never saw him. Matters took their usual course. Before we left California the young man announced their engagement. He hoped we would "fix it up" with mother and father, and of course we did. It is needless to say that the job was easy, for Ethel and her parents had long been regarded as a part of the Root establishment. There is a "whole lot more" we might tell of the courtship of the young people, but what's the use? It's the same old story—an ever lingering dream to some of us who have been there.

Very soon sorrow came into the heart of the young woman. Her mother kept up with her work until within a week of her death, and then passed away. The daughter bore up bravely, notwithstanding her mother was the last surviving relative. Shortly after, the young people came east and were married June 26 at the home of the groom's parents.

They are now in charge of the San Francisco office, where both are taking hold of life's realities as well as of an active business career, but Ethel is the beeman of the establishment.

Sandpaper or a Knife for Cleaning or Scraping Sections; a Lively Discussion between Two Authorities, both of whom have Scraped many Thousands of Sections

SOMETHING like two months ago we sent to Dr. C. C. Miller a new scraping-knife—one that we thought would do good work in scraping sections. We said it could be secured at a very low price, and we wondered if it would not make a good tool for beekeepers. In reply to this, Dr. Miller wrote:

Your inquiry concerning a knife for scraping sections leads me to say that "in this locality" a scraping-knife is a matter of little interest. Years ago we began using sandpaper in connection with the knife, gradually using the knife less and the sandpaper more; and a final suggestion from Allen Latham threw the knife almost out of use. The sections are taken from the T super, wedged up in a frame that is a little larger than the super and a little shallower; the roughest part of the propolis is taken off the bottoms of the sections with a scraper, but the chief part of the cleaning is done with No. 2 sandpaper. Then the whole thing is turned over, and the tops are cleaned the same way. As formerly done, the knife did all the rest, each individual section having its edges scraped, and whatever was necessary on any of the four sides. But when the Allen Latham suggestion came into play, the knife was discarded entirely for this individual section work, and it is all done with sandpaper. A sheet of sandpaper lies on the table, the sand up, and on this the section is laid flat. A few motions clean all four edges, doing the work in one-fourth the time the knife would do it, and perhaps doing it better. Any cleaning needed on the sides is done the same way. Of course, it uses up sandpaper, but, as Mr. Latham said, "There's plenty of sandpaper."

If cleaning must be done when it is very warm, then the knife has its innings, for to do good work with sandpaper it should be cool enough for the propolis to incline to brittleness. But generally there are more or less cool days, and one can take advantage of cool mornings.

We like the sandpaper ever so much better than the knife. Besides the important saving of time, the work is done more thoroughly. The sandpaper doesn't skip places as a knife can. Those, however, who have bulging sections produced without separators will need a knife for scraping edges. Possibly there might be some trouble with plain sections.

C. C. MILLER.

Dr. Miller's allusion to sandpaper immediately interested us. We remembered that it had been mentioned before, but our experience with it had not been entirely satisfactory. Our sections of honey coming in by the carload are scraped by us in the good old-fashioned way with a knife. Fearing we might have condemned sandpaper too hastily we submitted Dr. Miller's letter to the foreman of our honey department, Mr. Julius E. Gayer, and here is what he wrote:

This plan of sanding sections might be faster, but we don't like the work it does. It fills the paper very rapidly. If a drop of honey gets on the paper

it is dragged all over the outside of the section the next time you pass over it. There is great danger of racking the sections and getting a leaker.

It also throws dust into the open cells of honey. If the comb bulges, you of course get one that leaks, besides daubing up the sandpaper. We have been using sandpaper for about four years, but on an iron wheel which does the work. J. E. GAYER.

This note was intended only for our own consideration, and not for the public; but as it brings in some questions based on long experience in handling carloads and carloads of honey that has to be regraded and scraped, we give it for what it is worth. This we also submitted to Dr. Miller, and this in turn brought back another letter from him as follows:

Dear Ernest:—Yours of June 22 hardly needs reply beyond saying that you have sized up the matter exactly. What Mr. Gayer says is just what might be expected with sandpaper flying on a wheel at such a rate that it "cuts so rapidly that it sometimes wears off the edge of the section so that the sandpaper itself touches the comb." We have no wheel except Miss Wilson's very efficient pair of hands. As I have no personal experience in the work, I took up Mr. Gayer's objections with Miss Wilson, point by point, and will try to give her replies.

1. *It fills the paper very rapidly.*

"So it does; but, as Allen Latham says, there's plenty of sandpaper, and the time saved pays several times for the extra sandpaper."

2. *If a drop of honey gets on your paper, it is dragged all over the outside of the section the next time you pass over it.*

"Sometimes it happens that honey is daubed on the wood of a section, in which case it is wiped clean before sanding. I don't remember ever to have had a drop of honey fall on the paper from a section. If it did it seems I should have noticed if any trouble came from it; but I have no recollection of any such trouble. Could the rapid revolution have anything to do with it?"

3. *It also throws dust into the open cells of honey.*
"Not here. Dust doesn't fall uphill. May be it might with the blowing of rapid motion."

4. *If honey is bulging, you of course get a leaker besides daubing up the sandpaper.*

"That's true. We rarely have bulging—very rarely; and when it happens, sandpaper cannot be used for the edges—only the sides."

5. *Great danger of racking the section and getting it to leak.*

"Not as much danger of racking the section as when cleaning with a knife. It might be different with very rapid motion. I don't remember ever racking any with all I've ever done."

It seems pretty clear that the hands have it over the power sand-wheel. Fortunately, hands are also more plentiful than power sand-wheels.

C. C. MILLER.

This was again submitted to our Mr. Gayer, who replies as follows. This note also he intended only for our private consideration.

Our remarks were based on sanding the sections just as Dr. Miller suggested in his letter. We did not use the wheel, but used a sandpaper tacked on the table as he described.

We don't mean honey dropping from the cells, but inside of the section, which probably leaked out in transit.

Remember we are at the other end of the ship-

ping line, with different conditions. There is some difference between honey taken direct from the hive and receiving it after having been shipped a great distance.

Dust does rise, especially on plain sections, but not so much on beeway sections. J. E. GAYER.

As we did not seem to be getting anywhere, we told Mr. Gayer we should like to try out the sandpaper ourselves. Our first tests were decidedly satisfactory; but still we noticed that the edges of the sections were roughened up somewhat (more so than with the knife) and that fine dust would be deposited on the surface of the comb honey to a slight extent, also that the paper filled up with the glue. We came to the conclusion that sometimes the sandpaper was better, and sometimes the knife.

If Dr. Miller (or more exactly Miss Wilson who does the cleaning) were to try to sandpaper the sections that come to Medina from different localities of the United States, he (or she) might find it wanting, as does Mr. Gayer. Much depends on the temperature of the room and the general character of the propolis, for propolis, as is well known, varies according to the locality from which the bees gather it. That is only another way of saying that in some places the scraping-knife will work better than the sandpaper. At all events, this is the season for trying the scraping-knife and the sandpaper.

It might be well to say that our comb honey is largely in plain sections. The four edges of this scrape easier with a knife than the two edges and the two insets of a beeway section. On the other hand the last-named section might handle easier on sandpaper.

There is one more point that must be considered besides temperature and locality; and that is the exact shape and edge of the knife as well as the coarseness or fineness of the sandpaper. In any discussion relative to sandpaper, we hope our readers will be sure to mention what number of paper (the degree of coarseness) gives the best results. If you are talking about knives, tell us whether it is a kitchen knife with a thin blade, or a caseknife with a stiff blade, or a stocky butcher-knife. Again, is the edge sharp, suitable for paring potatoes? or is it ground square so that the two right-angled edges of the knife do the work? We are liable to get all mixed up in our discussion unless we know what the other man is talking about, and the writer, therefore, cannot be too precise.

We shall be glad to get reports from those who have been trying both side by side, and the decision regarding the relative merits of the two.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

As further reply to "A subscriber," p. 554, I may say that I had virgins cross the ocean before mating, and they did excellent work as queens.

On page 591 it is estimated that four men can by hand clean ten cases of honey in an hour. Those four men ought to take lessons of a woman I know of in this locality.

FRANK A. GRAY sends samples of white clover (one of them looks like alsike) and a yellow kind called Canada clover, and wants to know if he is right in counting the yellow much inferior to the white. Entirely right, I think. Except yellow sweet clover, I know of no yellow clover of value for honey.

THE *British Bee Journal*, p. 229, copies a clipping which says that in that country one firm uses an average of 40 tons of honey per month in the manufacture of a certain cough mixture. Even counting the short tons of 2000 pounds, that means 2630 pounds a day, or nearly a million pounds a year. Some honey.

C. V. CONOVER, that's a bright-looking scheme of yours to save foundation, p. 584, but unless you use excluders I should expect the queens to go up and lay in the drone comb sure to be found in some of those centers. Then for every $\frac{1}{4}$ cent you save on foundation I should expect you to lose $\frac{1}{2}$ cent in the amount of honey obtained.

B. C. AUTEN, you've no consideration for my comfort—made me get up off the lounge where I was comfortably reading GLEANINGS to go and smell and taste the water in the bees' cork-chip drinking-tub. You say, p. 583, it "will get foul in a few days." Mine had stood the whole season, but I found not the slightest foulness. Didn't you forget to put salt in yours?

E. F. ATWATER says, p. 547, that not one queen in a hundred will go up to lay in sections if bees build drone comb there. But they do, friend Atwater, here. If my bees have a chance to build drone comb in a section, it is the common thing to find such cells left empty for a time, awaiting the coming of the queen, and about 25 queens in a hundred accept the hint. You speak of economizing with a half-sheet or V starter. Do you believe it's *real* economy to use anything less than full sheets?

WET. That characterizes the season of 1915 in this locality. At the end of July,

although clover is abundant, bees have been kept indoors by the weather for four days, and it's been somewhat the same throughout the month. However, there may be no loss in the long run. The extreme wet continues the clover in luxuriant growth, and the prospect for a continuance of bloom looks just as bright now as a month ago.

Later, August 3. Still raining, and clover still growing. [See editorial.—Ed.]

J. E. HAND says, p. 489, that 14 frames is the limit of practical expansion. That would probably mean that there would be 12 or 13 frames of brood. Not many queens reach that. But some go beyond it, and possibly a good many more might if they had the chance. But the question arises, Do the bees have a fair chance? Generation after generation they are confined much within their capacity, and does not this have a tendency to lessen that capacity? [You do not touch on the great question raised by our friend Mr. Hand, whether or not it is advisable to have one large brood-chamber or a multiple of two or more of medium size, and tier up in order to get the necessary capacity. Your opinion on the proposition would be interesting.—Ed.]

"BREED from the best" has been my slogan for some time. It's the one thing I'd especially like to leave as a sort of legacy for beginners. So I'm grateful to J. E. Crane and E. S. Miles for that closing paragraph, p. 483. They're dead right in saying bees vary, and that their varying traits are transmissible, and so "breed from the best." [We should like to know what you mean by "breeding from the best." Said Vernon Burt to us the other day, "I like gentle bees; but I have about made up my mind that if I want honey I shall have to take bees that are a little irritable."]

Now, doctor, what is the first thing you look for in the "best"—the ability to pile up honey in the supers, or a combination of all good qualities, including gentleness? In other words, are you willing to put up with irritability and general all-around meanness in the way of robbing, bad color, and poor markings for the sake of getting stock that will winter well and secure a crop of honey? The two last qualities go hand in hand. Bees that die in winter or are weak in the spring can't get honey later. In short, doctor, tell us what you mean by "breeding from the best."—Ed.]

J. E. Crane

SIFTINGS

Middlebury, Vt.

Sixty pounds of extracted honey to the can. Yes, that is just right. Will producers please remember?

That "Amateur" may be an amateur at beekeeping, but in describing "the beekeeper who is never stung" he is more than an amateur. He is an artist—page 506, June 15.

I was greatly interested in the mammoth leaves of sweet clover, page 537, July 1. May its blossoms be proportionately large, with every one dripping with the choicest nectar.

As the season for fairs comes around it should be remembered that there is nothing that attracts bees so quickly as overripe pears and bananas. If these are kept protected from bees it is not difficult to keep them from confectionery.

F. C. Chadwick quotes A. D. Wolfe as saying that "if a stand or two of bees is kept in each orchard, the fruit will be larger, better-flavored, better-colored, more abundant, and of better keeping quality." This is giving the bees a great deal of credit for their work.

I may have spoken of it before, but I will mention again that I find many trying to cure American foul brood by caging the queens or making them queenless—in fact, by European-foul-brood methods. Don't do it. It is no use. They are sure to come down again with the disease.

I was told to-day how one farmer learned that stock would eat sweet clover. He cut the pesky stuff at the roadside; and after leaving it out for weeks in all sorts of weather he drew it to his barnyard for stock to trample on and make manure. Strange to say, his cattle left his carefully cured hay and ate the badly weathered sweet clover instead. Let us take courage. "The world do move."

Do we sing as we work? It is interesting to note that the birds sing the most when they work the hardest during the season of nest-building and the rearing of their young. If we cannot sing we may at least read the verses in "The Dixie Bee," for Grace Allen seems to bubble over with song

like the birds. Glad we are to learn more of her beekeeping experiences through her department.

I have been much interested in watching bees working on the buds of a clump of peonies near my door. The buds are almost the exact color of the leaves, and, more, the clump is hidden by the house on one side and lilacs on another, yet the bees have no difficulty in finding them. From this I infer that the sense of smell plays quite as important a part in bees finding nectar as the sense of sight.

In bulletin No. 151 of the South Dakota Experiment Station we find a letter from R. A. Morgan stating that he would not hesitate to give \$25 per acre as rental for the exclusive right of his bees to pasture on each acre of white sweet clover to be grown within 160 rods of his apiary, this offer to be good up to 100 acres. He estimates that the bees would gather from each acre \$100 worth of honey, wax, and pollen that would be valuable to the apiarist.

Were there ever two seasons alike? I have many times thought that a certain season would prove to be like some other season I have known in the past fifty or sixty years; but somehow they all turn out differently. The present season is a curiosity. We had a heavy rain about the 25th of February, ending in several inches of snow, when the rain seemed to be over for the season. Scarcely an inch of water fell from that time till June 11, when we had a very good fall with occasional rains until June 30, when it was again very dry. Then it began to rain, and kept it up for eighteen hours. There was plenty of clover on the ground in early spring, but it looked as though it would all dry up; but the ground was so mellow that the moisture came up from below, and clover began to bloom earlier than usual. After the rains began it was so cold and windy that bees could do little. During the last half of May there were many frosty mornings, and even into June, some of them severe. Bees have been whipped out by cold winds and hard work. Not until June 28 did we have good honey weather, and but little surplus has been secured. Now, Aug. 1, the ground is again soaked, and we may yet secure a fair crop of honey. There have been very few swarms up to this time.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas.

While the Texas honey crop will be somewhat short as a whole, some beekeepers have made very fair crops. These are scattered considerably, however, over the state. While the crop is short there was quite a good deal of honey, with a good demand for it.

Grassy apiaries are exceedingly dangerous these dry seasons on account of destruction by fire. Just a little spark from the smoker may mean the end of the entire apiary of some beekeepers I have visited, where the grass and weeds were knee-high and as dry as powder. Clean them up!

"Don't give up the ship" is mighty good advice to those who may become discouraged because they did not make a good crop this year. Be kind to your bees and do not neglect feeding them if it becomes necessary. By all means save them, as they may reward you thrice over for your kindness next year.

"Bulk comb honey" and "chunk honey" are two different things, yet some of our friends of the North and East frequently make the mistake of referring to our bulk comb honey as "chunk honey." Get away from that! You may seem to think it all right to do so, but we don't. We think it betrays a good deal of ignorance on the part of the person so using the right and the wrong names of this thing, and we hate to think that. It is, therefore, better to use the names correctly.

"HONEY IN THE ICE-BOX."

The editor calls attention to the foolish habit which some merchants have of placing honey in the ice-box. I have given many instructions to my customers in time gone by, along exactly the same line. Of late, however, my instructions have been just entirely opposite. I'll tell you why. I made a discovery by chance. A tumbler of honey found its way from the table into the ice-box with the other things by mistake. It had just come from the ice-box on to the table when I ate some of it with my hot cakes. What a difference between it and the usual thinner honey as we find it, and especially during warm weather!

Since then my instructions to customers have been to place the table dish in the refrigerator if they wish to enjoy improve-

ment in already good honey for table use. Since these instructions were given, the consumption is greater because they enjoy the nice, thick, cool honey far better than they would if it were in the original state. And I do not see that any harm can come from such procedure. Of course, it would be wrong to place the entire vessel containing a larger quantity of honey in the ice-box. [Our editorial referred to was aimed against the storing of honey in the *dealer's* ice-box; and comb honey, of course, should never be placed in a refrigerator, whether in the home or in the store.—Ed.]

BEEKEEPERS' FIELD MEETINGS.

I have been calling the attention of beekeepers, especially of Texas, to the great importance of holding field meetings and beekeepers' picnics from time to time. The Bexar County Beekeepers' Association recently held such a picnic, and it was indeed a most successful venture. This association is one of the liveliest organizations in this state. It includes the beekeepers of the San Antonio district, as this city is the county seat of Bexar County. There is not only a good membership, but the most of the members are real live wires.

The picnic was held at the apiary of Mr. A. P. Heinen, at Southton Park, about ten miles out of San Antonio. A grove near the San Antonio River banks served splendidly for such an outing. With a bountiful supply of eatables and refreshments, and a regular feast of bee-lore, there was plenty of real enjoyment for young and old, for the ladies as well as the men folks. There were visitors from seven counties.

A short address by the president, Lewis Maverick, some pertinent remarks on the subject of bee diseases by M. M. Faust, of Floresville, followed by a talk on co-operation and organization by myself, was the program in the afternoon. All day there was free discussion and demonstration. Besides the regular hive equipment in its completeness in Mr. Heinen's apiary, E. G. LeSturgeon, the secretary of the association, had provided a great variety of hives and other beekeepers' supplies and equipment for exhibition. A person in charge of these supplies was kept busy all day at the various occupations of hive-nailing, putting in foundation, and the dozen and one other things that can be done to keep a crowd of lookers-on busy.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

The powers of Europe went crazy one year ago to-day, July 29, and the end is not yet in sight. The conditions of finances will not be normal for many years to come, and the bee industry will probably be one of the sufferers.

There is a movement on foot to market honey through a local orange-distributing agency. A splendid idea indeed! The vast distributing business of this agency should be of immense benefit to the producer. Now, if the beekeepers will pool their interests as the orange men do, and will be willing to take a uniform price for their honey according to the grade, we shall have made a great step forward. Grading will be a difficult problem. Blending should be a feature of the business that a uniform grade could be offered to the buyers, and not to exceed four grades should be the aim.

Among my visitors for the month was Mr. S. M. Boschnogel, of Loudersburg, Pa. Mr. Boschnogel has made very extensive travels since leaving home the first week in June. He traveled east through the New England States, back through New York, then into Canada, and as far west in the Dominion as Calgary, thence south into Montana, Wyoming, Idaho, Nevada, Utah, and to San Francisco, San Diego, and Redlands. He had covered over 7000 miles when here, 400 of which he had walked that he might see more and study conditions better. He will add several thousand miles to his trip before he reaches home next fall, and will have visited many prominent beekeepers and most of the scenic places in the United States.

During July I spent four days in the higher San Bernardino Mountains, and, as usual, kept my eye open for bees. I found them quite numerous at Bluff Lake, a resort over 7500 feet above sea-level. There were numerous blooming flowers and shrubs for them to work on; but what caused me the greatest wonder was the immense amount of honey-dew on the fir-trees. The leaves were shining like crystals with the honey-dew that has dried and crystallized on them. The bees seemed to be able to work it only in the morning, to any great extent. There was fifteen feet of snow at this point last winter, some remaining until the first of

June, so I am wondering what the real length of the season is at that altitude. Frost is known to come very early. In fact, there was a heavy frost one night while I was there. It seems to me that three months would be about the length of a season to expect there.

In the issue for Jan. 1, 1912, is an article by Arthur C. Miller entitled, "A few random notes on the way bees 'make' honey." At the time I read this article by Mr. Miller I could not bring myself to believe some of his contentions, but resolved to give them some careful consideration and study. I have had the above-mentioned issue of GLEANINGS close at hand since that time for reference to his article. Mr. Miller says that a bee returning does not rush for a cell in which to store its nectar, but, on the contrary, she spends a seemingly needless amount of time wandering about and inspecting cells. I have seen nothing in the past three years that gives me any foundation for believing that Mr. Miller is correct.

Quoting again, "When the bee has emptied her sac she backs out of the cell, wipes off her face, antennæ, and tongue, stretches and plumes herself, and, likely as not, crawls into some cell or hangs in some quiet corner for a nap. Thus she may stay for a few minutes or for half a day." The above is the hardest of all for me to believe, and I regret that I must say it seems to me to be without sufficient foundation. I have made some experiments with field bees, and the length of time it has required them to return to baits placed for the express purpose of timing them. The tests have been so conducted that there could be no reasonable doubt as to getting the exact time it took a bee to get its load and return for the second and third. In none of these tests have I found any disposition on the part of the bee to loaf on the job as Mr. Miller suggests.

I will admit that I have not spent half a day watching a single bee to see what its actions are in the hive for that length of time—whether it crawls in a cell or hangs up in a corner for half a day. I do not believe that a single bee can be kept under observation for that length of time if the weather is sufficiently warm for them to move around freely, and the bee is in active condition. There are many things in the entire article that to me savor of speculation.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

USING TWO-STORY BROOD-CHAMBERS

"In using brood-chambers two stories high, which is better—the eight or ten frame Langstroth hive? I am told that, for section honey, two-story eight-frame hives, or sixteen frames, are best until the time to put the supers on; then one story is to be taken off, reducing them to one story or eight frames. In this locality the honey harvest opens and supers should be put on somewhere about June 5, and up to that time the queen rarely occupies or fills more than eight frames with brood. Under such circumstances would it be necessary to put on the second story?"

If a single story gives all the room the queen will occupy, and if no more room is needed, then there can hardly be any advantage in giving a second story so far as the part of the queen is concerned. But no one can be perfectly sure in these matters if he has never tried it. You can hardly be sure that none of your queens will occupy more than eight frames until you give them a chance. Bees do not freely use either of the two outside combs for brood, but use them mostly for honey and pollen. If brood is found in either (and it may be found in both) they are somewhat crowded for brood-room. If you find eight combs occupied with brood in an eight-frame hive, the probability is that more than eight frames would be used if the bees had two stories. A strong colony in two stories may have from ten to twelve frames of brood. Some colonies do not need the second story, even with an eight-frame hive, but many more do. If you practice using two stories you will find a good many more of your colonies needing them than you thought. Giving all the room needed results in stronger colonies.

But why be confined to an eight-frame hive? With a ten-frame hive a good queen will give eight frames of brood and some brood in the two outside combs, as much usually as is found in the two outside combs of the narrower hive. This will satisfy most of the queens you are likely to have, and put a larger force of bees in the fields at the time of your surplus flow of nectar. If you wish to contract so as to throw more of the bees and honey into the sections, put a dummy in place of each outside comb at the opening of the surplus flow. This will answer the same purpose as reducing the two-story eight-frame hive to a one-story.

In order to secure honey we must have

bees. As a rule, the more bees the more honey. If a queen has filled all the available cells in eight frames, two more additional frames will give more bees, and, consequently, more honey. Then if, at the beginning of our main nectar flow, we prefer honey stored in the sections instead of the two outside combs, let two dummies take the place of these, and we are brought back to an eight-frame hive again with approximately one-fourth more laborers to work in the nectar harvest than if we had used only an eight-frame hive all the while.

Now as to the two stories. A queen that has eight combs well filled with brood just at the approach of the honey harvest will not fill eight more as completely as another queen would have if she had had them early in the spring. What extra brood she does put in the upper story will hardly give bees that will labor to advantage in that harvest. Bees in their prime as laborers when the honey harvest is at its prime are the ones which make the profit.

The profitable keeping of bees does not depend so much upon having each queen occupied to her full capacity as it does in having the combs and hives occupied to their full capacity, and that at just the time when the flowers which generally give surplus honey are in bloom. Taking advantage of this thought, and by using the ten-frame hive as a single story up to within twenty days of the opening of the surplus bloom, and then putting a queen-excluder on top, and on top of this another ten-frame hive filled with good worker combs, a two-story hive can be made a paying investment. Swarming can be kept back till the lower hive is nearly filled solid with brood, and quite a start in honey made in the upper hive by way of storing honey, which start accustoms the bees to storing above.

As the surplus bloom arrives, reverse the hives, put a super of sections between, and see that the queen is in the now lower hive with the queen-excluder under the super. The bees will remove the honey that has lately been stored there to give place for the eggs from the queen, and this honey, together from that coming from the fields, will go into the sections almost at once. Ten days later, shake the bees from seven of the combs now in the upper story, at the entrance below, and set the upper hive on a new stand, thus getting a new colony. By adding supers as needed, success is yours in good seasons.

GENERAL CORRESPONDENCE

THE DEVELOPMENT OF THE HOME HONEY MARKET

BY L. L. BURR

That each individual honey-producer should always make an effort to develop his local market goes without saying. Yet it is also a well-known fact that many of the large producers make no effort whatever to increase home consumption. They say they are honey-producers, not salesmen. Such an attitude is all right when prices are good. At the present time, however, all honey-producers should be cognizant of the fact that a condition exists that did not exist in years past—namely, the war in Europe.

As a result of the war a condition exists which will continue to exist as long as the war lasts, and perhaps for a period following. The result is that a large proportion of the honey of the West Indies and of Central America that in the past was sent to Europe will now find its way to the United States. From this there can be but one result—that is, lower prices; and it behooves the producers of honey in this country to develop their home markets to the utmost if they desire to secure the best results in disposing of their honey crop, for the large cities are going to be flooded, and the prices there cannot but suffer.

In the following, what I have to say on the subject of selling honey is from experience; and perhaps I may have something to tell from that experience which will be of assistance to others.

I do not remember the first honey I sold. I did it all through my boyhood, and enjoyed the work. In selling honey, as in every other business, there are certain ethics that it always pays to observe if one desires to build up a substantial business; and according to my idea they are as follows:

1. If you are going to sell to the retailer, do not peddle honey to the housewife in the same locality. I might here state that, as to the matter of peddling, I am innocent. I have never sold to any person but the merchant, and so know nothing from per-

sonal experience about that art. I do know from observation that nothing makes a small-town merchant so sore as to have a man sell him some product, and then go out and peddle to that same merchant's customers. Where that is done, and the merchant becomes aware of the fact, there is but one result; and that is, the merchant will tell such a seller that he will see him in Hades, and wish him all the tortures that the property room contains, before he will purchase from him a second time.

2. If it is a small country town with but a few stores, pick out the most progressive merchant and inform him that, if he agrees to handle your honey, you agree to furnish to him alone, and that you will not sell to any of the other merchants. From my experience this is far more satisfactory than trying to deal with all the store-keepers, as the one would sell practically as much honey as all of them put together. Should the town be large, pick out one merchant in each neighborhood; and in each case be sure to let the merchant you deal with know that you are not

going to sell to some other merchant across the street or around the corner.

3. Make your prices standard in each town. Don't sell to one merchant for one price, and then later sell to some other merchant in the same town for less money. If you do you are breeding trouble. There are merchants who want only the very finest grade of honey, no matter what the price; yet it is well, when furnishing honey to such merchants, to let them know what your prices are for other grades, and explain the difference in grades, so that they can distinguish them themselves if possible; in other words, treat them in such a way that they cannot help knowing that you are dealing with them on the square.

4. The sections that can be seen through the glass should be a fair indication of the entire contents of the case. When a mer-

WOULD YOU?

BY GRACE ALLEN

Oh! who would live in cities
When the blue is in the sky,
And walk resounding pavements
When the grass is thick and high?
And who through crowds would jostle
When the fields so broad are spread,
And gaze on smoke-drab buildings
When the rose is blooming red?
And who would brave the noises
Of the city's rushing roar,
When gentle bees are humming
As they never hummed before?
Oh who would live in cities
When the country calls so true,
Or compromise in suburbs?
I would not! (But I do!)

chant finds out that your goods are packed that way, you are never going to be bothered by having him go through the case to see just what your grade of honey is.

The foregoing are ethics that I always observed in the days when I sold honey. It may be possible that conditions have changed since then in regard to No. 2, and it might not always be advisable to follow it.

Simply observing business ethics, however, will not of itself sell honey to a merchant who is doubtful as to whether honey is a product that he can sell, or to one who is prejudiced against handling honey; but such ethics will assist in retaining customers after you have once secured them. As we all know, there are all kinds of people who are storekeepers, the same as in other kinds of business, and the same line of talk or procedure that will sell honey to one grocer will not work with all. The following, however, are a few stock suggestions:

With the merchant who says that he has no call for honey, and does not think that he can sell it, quite often it is advisable not to waste words with him trying to get him to part with some good cash; but make the proposition that you desire to leave with him one or two twenty-four-section packing-cases, with the understanding that he is to set it on the counter in plain view of his customers; that you will return in about thirty days; and if in that time he is of the same opinion you will take what is left on his hands, and allow him the regular profits on that which he sold.

There is always the merchant who will tell you that honey is sticky stuff to handle, and that he does not want it in his store for that reason. To them explain that your honey is placed in non-drip cases, and that the case can be placed anywhere with no danger of leaking. It is also well to point out to all storekeepers to whom you sell honey that there is a top and bottom to sections, and that a section should always be placed with the top side up.

There is a great deal written these days about the "psychology of salesmanship," whatever that may mean. I knew nothing of psychology in the days when I sold honey, which was from the time I was some twelve or fourteen years old until I was eighteen years of age; but I did find that, to sell honey, one must have confidence in himself. Be ready to talk bees at all times to any storekeeper, his clerks, customers, or any other person willing to listen. Always let it be known that you thoroughly understand bees and the production of honey, the natural history of the bee, and the history of honey production. A man, to sell any article successfully, has to understand thoroughly the particular article he is selling; and there is so reason why the average beekeeper who has enough nerve and stamina to produce honey should not, with a little practice and experience, develop into a better honey-salesman than the average professional salesman who knows nothing of the practical side of bees and honey.

SELLING HONEY FROM HOUSE TO HOUSE

BY WALTER S. POWDER

I am now in position where I have nothing to sell, and I feel that I can talk to my beekeeping friends without any suggestion of free advertising. Much is being said about overproduction in some localities, while a shortage exists in other places, and that this situation should be equalized and prices advanced. I believe the situation can be solved; but up to this date it does not seem to be a practical problem for organizations.

A man who has traveled extensively in Indiana as a bee inspector submits the following figures. He estimates that our 92 counties contain about 2000* colonies each, which would mean 184,000 colonies in the

state, and that on an average season each colony would produce 30 pounds of surplus honey. These figures may be a little inaccurate either way, and yet one can perceive that an immense amount of honey is produced in this state. The point that I now wish to bring out is that Indiana does not produce enough honey for state consumption, and I do wish I could tell how many carloads of honey are shipped to this state from the North and West every year, all of which finds a ready sale. I know that some of our neighboring states are in the same line with Indiana.

Honey is one of our greatest luxuries, and as a health food not one word has ever been said against it. Yet thousands of families do not provide it on their table as often as once a year. Beekeepers have traveled a rugged road, especially before

*Striking an average is difficult, but from another source we have figures that seem to make the average for the state a little less than 1000 colonies per county.—Ed.]

our pure-food laws were enforced, and now what seems to be sought mostly is better distribution. I can say without boasting that I have had extensive dealings for many years as a dealer in honey, and many interesting observations have come before me.

For a number of years I have been deeply interested in supplying men with honey that they sell from house to house. Some have failed, while many have made it a decided success, and I have tried to analyze the situation. I find that the man best suited for this work is he who has an apiary, even though it may be small, because he can talk about bees in an intelligent manner, and this goes far in making sales. He can begin his work by disposing of his own product, and then secure large shipments from localities that are oversupplied.

Among all the different features that are necessary to success is to keep up the quality. Quality means that one can go over the same route and find an increased list of patrons; and when honey of quality is placed on the table, visiting friends will make inquiry as to where so fine a brand of honey was secured. I personally know of several who have established routes on this plan that earn for them as much as five to seven dollars per day. Those who are most successful are pushing the sale of extracted honey; and that they keep up the price seems to help advertise their business.

I have watched two men of equal ability start out, one selling at 15 cents per pound, while the other sells at 20 cents; and the 20-cent man invariably secures the most business per day. Seemingly the higher price carries confidence with it. With some there is a tendency to increase their profits by putting out inferior honey. These are the men who fail. Inferior honey will never promote business. I have seen it so inferior that it even contained foreign substances; and while a few sales may be made, those securing such honey are likely to resolve that they never again want any more honey.

The work described can be made very pleasant, and no deceptions are required. The successful ones carry a sample, call at the kitchen door, and insist on the housewife tasting it. One of these men disguised himself as a farmer, wearing boots with his trousers tucked inside, and began by telling a story about "just drove in from Southport; and while my wife is doing a little shopping I thought I would try to sell some honey, as my bees did quite well this year." He disposed of a good deal of honey, but did not continue very long. He is the same man who asked for a drink of water in a

kitchen, and then asked the landlady how to turn the faucet to get city water; and after she showed him he remarked, "How nice! I supposed you had to work a pump-handle like we do at home!" I think he overdid the thing; but the lady surely thought of him as an honest farmer.

Another successful salesman, whom I was supplying, solicited near my home, calling on my immediate neighbors. My neighbor told him that she used honey, but had been getting her supply from Pouder's honey-store. He replied, "I know Mr. Pouder, and he sells good honey; but I wish you would just taste this sample." She tasted; and, lookingly at her inquiringly, he remarked, "Now, lady, I want to ask if you can get honey like that at Pouder's honey-store." She bought! We have men unemployed, and here are opportunities going to seed. If pushed, there would be an increased demand at higher prices.

I have had much personal experience in disposing of bottled honey to the retail grocery and drug trade. This was in the days when we had no pure-food laws, and I found it an uphill business, as I had to compete with jars containing a strip of comb honey, the jars filled with glucose. They really had an attractive look, and did not granulate on the shelves. I could not successfully compete with such goods; and at best my margins were small, wagon delivery was an expense, accounts were opened up, and collections very difficult. I would have abandoned this branch of the business earlier had I not looked forward to drifting my business to wholesale houses. I felt, however, that I could not interest the wholesaler till I had created a demand at the retail stores, which proved to be true.

During one season I sent a solicitor over the state who brought considerable business, but could not be called a pronounced success. Merchants hesitate to order goods in small lots, and prefer to secure such goods as honey with other larger shipments, thus reducing transportation charges to a minimum. Advertising Pouder's honey in newspapers has always been a failure with me; but getting bottled goods in wholesale houses is the best method that I have ever learned for distributing this class of goods. Supplying their traveling representatives liberally with free samples at times when business seems dull gives it an impetus. Some of my best business in this line resulted by using labels from the wholesale houses instead of my own.

I sometimes wonder if we are as grateful as we ought to be for the pure-food laws that we have to-day. I used to return from

a soliciting-trip discouraged, for it seemed to me that many of my clients actually seemed to prefer the adulterated goods, and even on my best days my margins were exceedingly small. I recall one instance where a druggist greeted me cordially, looked at my sample, and remarked, "I have a recipe

for making honey just like that; but if you will put something in it to give it a more amber color it will look still more like honey." I kept back my fighting blood with much effort, and later he became one of my regular patrons.

Indianapolis, Ind.

AROUSING INTEREST WITH A TRAVELING EXHIBIT

BY D. W. HOWELL

Finding that I should have a crop sufficient to be of interest, and wishing to secure the best price for it, I concluded to try selling from house to house, and see if I could realize more for my honey. So I hit on a plan of getting the attention of the ladies and children, or any one else who might be interested.

Taking my bees with me, and sample of honey, I started out one bright morning in May, going to a neighboring town. I stopped first at the railroad lunch-stand. The proprietor was very much pleased with my bees, and bought a can of honey. I then went to the dwelling-houses.

The traveling-case closed.

I sold in these three towns nearly 3500 pounds of extracted honey. I have a strong competition here in the form of a good home-raised Georgia cane syrup. Many prefer this to any honey. The syrup seldom sells above 50 to 60 cents per gallon—far below honey in price.

Now, if I could do this well in three small towns, and with strong competition, I think it would be an easy matter to sell honey by this plan where there is almost nothing to compete.

The traveling-case dissected.

I use a simple traveling observation comb in a case simply made. It is easily taken apart to remove the frame of bees and to clean it. The glass can be removed when the top is taken off, and I always make sure that they are clean and bright before I go off with the case of bees.

Stopping at a house I would get the lady of the house to look at the bees and the queen. I would then show her the honey, telling her about the size and weight of the cans, and also getting her to taste of the sample, with one of the small strips of clean white paper I carried with me for the purpose. In this way I would quite often get an order. I found that I could get 10 to 12 cents for good extracted honey sold in this way, when others could not get any more for good comb honey.

My nearest town each way by rail is ten miles. One has a population of about 1500, the other about 3000. My home town has a population of about 1000. By this plan

The last days of October I had occasion to visit a city of 50,000 inhabitants. I had about 200 pounds of honey left; so I concluded to try my case of bees in a larger town. I had no trouble in disposing of all the honey I had left, and could have sold more, all in about one day.

In this place I sold extracted honey at 12 cents per pound and to all classes of people, and only in the business part of the city. I did not visit a single residence during the day. I found that the ladies were my best customers; and to try this out fully I went to several drygoods stores where a number of ladies were employed. They were very much pleased with the bees, and I received more orders for cans of honey than at any other place.

On this trip I carried about one hundred

GLIMPSES OF IOWA BEEKEEPERS—By FRANK C. PELLETT.

GLIMPSES OF IOWA BEEKEEPERS

7. Miss Merta Mitchell, Keokuk, Iowa, uses a tripod and wire stretcher for a combined hive lifting and weighing device. 8. H. B. Morrison, Fayette, Iowa, sells most of his honey from an auto.
 9. B. L. Scarlett in his apiary at Anita, Iowa. 10. Apiary and honey house of J. I. Wiltse at Arlington. 11. Home of C. A. Gallagher at Maquoketa. 12. Hon. Eugene Secor and a mock orange in his apiary at Forest City.

of the folders. "The Food Value of Honey." Using them as business cards I had stamped on the back of each, with a rubber stamp, my name and address. These I would give to each one that bought honey, and to others where I thought best.

In using this plan, be sure to have bright, clearly marked bees, and a bright young queen. It is best to have a small amount of brood in the frame, and let it be a frame that belongs to them.

Make sure there is plenty of ventilation at each end of the case, as this will help to keep them contented on hot days more than anything else. My case is built for a shallow extracting-frame $5\frac{5}{8}$ inches deep, which I find is about right to carry, and can be handled easily. The bees will stand several days' confinement if they are young, have sufficient ventilation, and some honey to eat.

I use several shallow eight-frame extracting-supers as a nucleus to draw these frames from, keeping good young queens in them. I do not carry the same queen with me every time, but give them a rest. By maintaining a nucleus one is able to find the frame best suited for carrying in this way, and have a chance at getting young bees. If the nuclei get too strong, give some of their bees to a weaker colony.

In going around with the bees, be sure to interest the children all you can, letting them look at the bees and taste the honey. Leave a sample where it would appear to good advantage. Samples will often sell some of your honey easier than you can yourself.

You should be well posted on bees, and be able to answer a great many questions that will be asked. The average person knows very little about them, and will ask some questions that will be hard to answer in a way they can understand.

One of the most common questions asked was this: "How did you get the bees in the box?" Many of them had very queer ideas as to how this could be done. Many questions were asked about the queen, and what she did in the hive. Some would have the idea that she is absolute ruler, and would make the remark on seeing her the first time, "Doesn't she make them stand around?" Much surprise would be expressed when they were told that she does not rule the hive, but is its mother; that she will at times lay more than two thousand eggs in a day, and that she is the only bee that lives twelve months or more.

Shellman, Ga.

THE FACTOR OF CLEANLINESS IN HONEY DISTRIBUTION

BY JOHN W. LOVE

Whenever a housewife in Naples wants a morning quart of milk for the bambino all she has to do is to waylay the milkman as he drives his flock of goats through the narrow streets. The proprietor of the dairy milks the goat, shooting the fluid into any bucket or bottle the customer happens to have with her. The only merit in this system is its cheapness.

It is a long way from the simplicity of the Neapolitan goatherd to the business acumen of the distributor of a trade-marked milk who buys from scores of dairy farmers, maintains a dozen condensaries, advertises in national magazines, and hands his product to you in a labeled can which is attractiveness itself.

The one calls at you from the street, the other buys magazine space to show pictures of "contented cows." You drop a few centesimi to the Italian for a quantity of milk you both guess at. The other milk comes at fifteen cents a can, always the same amount, about enough to make a quart when thinned. In these and other differences lies much of interest, some points of

which may be applicable to the business of selling honey.

One of the reasons for the eagerness with which the public has taken up the trade-marked crackers in preference to those scooped out of barrels is the superior cleanliness of the article put up in packages. The progress toward ultra neatness is part of that greater movement in sanitation which, during the last century, has taken the terror from many diseases and entirely extinguished a number of them. It is part of the same movement which has cut down infant mortality and boosted the average expectation of life. Absolute cleanliness is built into the new civilization. Those who fail to come up to its standard are finding themselves left with the reactionaries and forced out of business.

It is true that honey is now seldom sold in bulk, like vinegar or cider. Only in localities does one still find a beekeeper peddling in open buckets. Indeed, the beekeeper, feeling the dignity of his profession, is dropping the word "peddling" from his vocabulary. But bottles and cans of honey

Poorly built stone road over-grown with white sweet clover self-seeded from that growing by the roadside.—Photo by KARL JENKS, Medina, Ohio.

in doubtful sanitary condition cannot hope to compete with the canned glucose (corn syrup), apple-butter, and maple syrup, which the householder may buy instead of honey.

When the shopper looks over the rows of wares on a grocery shelf, which is she most likely to select—peanut butter in a glass tumbler neatly labeled with a picture of a beechnut with its suggestion of crisp frosty air and autumn woods, or honey in a foggy fruit-jar, sticky with finger-prints? Should that honey come into competition with another brand of the same product put up in clear bottles and trade-marked, the price difference will have to be great indeed to induce the modern housewife to select a more commonplace product.

Comb honey put up in a dust-proof carton suggests delicacy and sanitation more than that displayed in a glass showcase. While the conditions within the case may be ideal, what may not have happened to the honey exposed on a dusty road, or carressed in the hands of the grocer boy?

The public taste for the article suggesting absolute purity you may describe as capacious or discriminating, according to your own temper; but it does no good to call it names. The mood will persist. It is the result of a quarter of a century's agitation by the food scientists, chemists, editors, the

national Government, and progressive manufacturers.

Nor is the use of trade-marking goods by the consumer necessarily a step away from real economy. This may be true in particular cases; but in such articles as whole-wheat biscuits the price and the amount purchased are universal and constant. Where the same things are sold in bulk the purchaser may pay a few cents less; but he buys articles which may be dirty or exposed to the moisture of the air or short in weight. Competition between dealers in the same food, or in foods which compete with one another, like "corn syrup" and honey, keeps the price as low as compatible with cleanliness and reasonable profit. A constant price and a standard weight are substituted for a price the dealer thinks he can get, and a weight which may or may not be accurate, according as the state inspects his measures or scales.

To preserve the superiority of a canned and cartoned article over the same thing in bulk, and at the same time to help lower the cost of living, some manufacturers are putting out what is known as the "family container." Honey distributors are finding it successful with extracted honey. The can will hold five or ten pounds, and in some cases is returnable when empty, with a slight rebate. The price can be held at only

a little more than the same article in bulk. With a label and a trade-mark, together with self-evident cleanliness, all the virtues of the small package are retained. Even ten pounds of honey is not an excessive amount if the cook can be told not to keep it in the refrigerator.

The whole trend can be summed up in a paragraph by Mr. Erwin McDonald in *The*

Forecast (New York): "Any going back to old conditions would mean a relaxing of watchfulness, a removal of responsibility, and a consequent loss of all that has been gained. In a pure-food movement there is no looking backward toward unsanitary methods because carelessly handled and unidentified foods cost a few cents less."

THE FACTORS THAT CONTROL THE PRICE OF HONEY

BY BENJAMIN F. KIRK

Honey "boosting" is just the best ever if properly done; but it must be done at a profit. It may not be that it must yield an immediate profit, but it must show symptoms of an ultimate profit. One correspondent for an American bee journal advocates the reduction of the price of honey in connection with increased publicity. Another suggests that an additional charge must be made to cover the expense of printing posters, display cards, newspaper advertising, furnishing displays for grocery stores, etc. Now, in the light of ordinary business sense, which one is right?

"Large sales and small profits" is a catchy phrase, and many are deceived by it. The trouble is, too many fellows who are doing a 5000 or 10,000 pound business seem to think they are the giants of the honey business. It seems to me that no one handling less than 100,000 pounds annually is justified in thinking he belongs to the "big business" class. If the Standard Oil Co. were selling only a few thousand gallons of oil yearly, instead of millions, the price of oil would necessarily be much higher. If a beekeeper does not get such a price that he can pay interest on the capital invested, depreciation on the equipment, hire every stroke of work done from the nailing of the hives to the selling of the honey, and still have a profit left, his business is a failure. The public will pay the price if the beekeepers demand it and furnish quality goods.

In a large part of the United States the bee and honey business has many uncertainties connected with it. Nearly every year

the beekeepers in some part of the country have to feed to keep the bees going till the next year. This uncertainty has driven some good beekeepers out of the business. But for some reason it rarely seems to affect the box-hive apiarist very much. It's true he's out of business for a year or two, and then he catches a stray swarm or two, and again starts his business of throwing chills up the spine of the neighbor who is trying to make a living in the business. In many ways the correspondent's idea of licensing the beekeepers sounds well; but where would it end? Wouldn't the hog men, the cattle men, and others ask for the same method of eliminating the undesirables, and, at the same time, unpleasant competition?

I do not believe there is one city of 10,000 inhabitants or over in a certain central state that is using the amount of honey that there is a market for. When I speak of the possibilities of a market I mean the profitable possibilities. A town can be worked so frequently and so thoroughly that the last time over will not yield a profit. Along another line of business an old gentleman used frequently to say, "Go slow, and learn to peddle." It takes considerable will power for some people to force themselves to do the house-to-house selling stunt. But it is where the average beekeeper will find the profit. A medium-sized production of honey sold direct to the consumer at the retail price pays more profit than a much larger production wholesaled. But it's a good thing for some beekeepers that most other beekeepers are too timid to canvass.

Indianapolis, Ind.

THE ADVANTAGES OF LARGE HIVES

BY F. A. CONNOR

The tendency for some time among several progressive apiculturists is toward the adoption of a hive that prevents the swarming propensity, gives sufficient capacity for

the most prolific queens, and can be contracted or expanded according to the requirements of the colony. A hive should be adapted to the production of comb or

My colonies in Jumbo extracting hives averaged 100 lbs. of honey.

extracted honey; it should make ease of manipulation possible, interchanging with standard bodies, supers, covers, and bottoms, and successful indoor or outdoor wintering.

Many hives called standard cannot accommodate one quarter of the bees, comb, and honey which in a prosperous season may be found in large ones, while their owners wonder that they obtain so little profit from their bees. It is very evident that profit can be derived from bee culture with almost any style of frame or hive, but it is also an established fact that in every pursuit some conditions produce better results than others under the same circumstances.

The number of frames to be used in a hive depends on their size, for we should manage our bees and give them such space as is necessary to obtain the best results. It is unquestionable that the quality of a queen depends on the quantity of eggs that she is able to lay. Then why limit her by adopting a hive as your standard so small that she cannot develop her fertility? I wish to take the opportunity of again asserting that my preference for large hives is based on an experience of nearly twenty years with hives of different sizes, and various races of bees.

In addition to the disadvantages of small hives, another—greatest and most important of all—is the excess of natural swarming which they cause. The leading advocates of small hives, some of whom are the largest

honey-producers, invariably acknowledge that they have too much natural swarming. The cause is, solely, contracted brood-chambers.

I find that among the manipulations that tend to discourage swarming, especially with the Carniolans, which are claimed to be excessive swarmers, is abundance of ventilation during the honey-flow, obtained by means of a large entrance, protection of the hive from direct rays of the sun, and plenty of storage room. I desire to mention that the hive I have finally adopted is the ten-frame Jumbo. These hives consist of two regular dovetailed Jumbo bodies, Hoffman 11¼-inch-deep frames; covers and bottoms, where used for extracting purposes.

One can adopt the Jumbo hive and still keep on using the standard Langstroth ten-frame hive and supers. In my judgment it is of the utmost importance to have a hive which standard supers and covers will fit, and one adapted to bottom-boards; and to such an extent am I an advocate of this hive that I have discarded all other sizes that were in my apiary.

As a non-swarmers, or practically so, when operated for extracted honey, this hive is unsurpassed; and as to the production of comb honey, I find that bees readily enter supers; and it is an ideal hive for purposes of tiering up. The brood-chamber is of such capacity that the most prolific queens rarely venture into supers or extracting-bodies, although queen-excluders are advisable. Colonies retain what nectar is placed

Boulder field meeting, June 12, under auspices of the Colorado Honey-producers' Association.

in the brood-chamber. These are ample stores for the most populous. With swarming controlled for the entire season, colonies will necessarily be well supplied with bees to insure perfect wintering.

I wish to impress on the mind of the reader the advisability of the use of large hives. Possibly I have given too much praise to this hive; but let me say here that

one should study his locality very carefully before deciding on what size of hive to adopt as his standard.

As to the race of bees, my preference is the Carniolan. I find that they are a very hardy and vigorous race, breed very early, and queens are very prolific; and as to honey-gathering qualities it is unsurpassed.

Worcester, Mass.

THE GUM-TREES OF AUSTRALIA

BY T. RAYMENT

BLUE GUM (E. GLOBULUS)

So named from the globular fruits. This tree is well known to Californians, and is most favored by foreigners for planting. It is not a heavy yielder of nectar, but it is splendid for pollen in early spring every

year. The best record the writer is aware of is somewhere about 56 lbs. per colony of amber-colored, rather thin honey, which candies rather quickly. Blue gum grows very rapidly, and coachmakers value the timber for shafts, poles, reaches, etc. It is

Part of E. Fleming's apiary and orchard, Victoria, B. C. Mr. Fleming suggests that this photograph might win a prize, if one were offered, for "artistic" irregularity. The hives are almost surrounded by small oaks.

indigenous to Tasmania and the coastal region of Victoria. At Leongatha, Gipps, Vic., there is a blue-gum stick standing that has had the top *chopped off* at a height of 97 feet. These forest giants are usually fallen about twenty feet from the ground, and the axed scarp is frequently large enough to permit a man reclining in it. Like all pollen from the eucalypti, that from the blue gum is creamy in color. It is needless to say the nitrogenous content varies with each species. The slits in the anthers that liberate the pollen grains are shown in the sketch.

YELLOW-BOX (*E. mellioides*).

From *mel* (honey), and *odor*-scent; therefore "honey-scented box." It is indigenous to the whole of the eastern states,

and is a most popular honey-tree. It blooms profusely every second year in early summer, and yields practically no pollen. For this reason, bees in pure yellow-box forest die for want of protein, notwithstanding the abundance of honey, which is pale in color, exceedingly dense, and of delicious flavor. A yield of 350 lbs. per colony is not considered very remarkable. The honey remains liquid almost indefinitely. Where the flats and swamps grow river red gum (*E. rostrata*) the rising land is generally clothed with yellow-box, so that the honey crop is a composite one. Women folks clamor for the hard heavy timber for stovewood. In Australia it is used for poles and railway sleepers. The details in the drawing are variously enlarged. The openings in the anther permit the pollen grains to issue. The nectar surface is depicted in the section of the flower.

RED-BOX (*E. POLYANTHEMOS*.)

Poly, many, and *anthemos*, flowers.

AUGUST 15, 1915

Appropriately the many-flowered box; for every second year the trees resemble giant cauliflowers. The very pale dense honey rarely candies, and is of fine flavor. This eucalypt blooms in early spring, and yields a little pollen and a great flow of honey—up to 150 lbs. per hive—over a period of three months. This species is found chiefly on stony, gravelly ridges in combination with some variety of stringy bark. The timber is ruddy, hard enough to gap the best American ax, and is very dense. It is much sought after for railway-sleepers, bridge-beams, and fence-posts, because white ants (termites) do not readily attack it. The foliage is bluish in color.

GIPPSLAND STRINGY BARK (*E. EUGENIODES*).

This eucalypt favors poor sandy country, and its period of florescence is so prolonged that weak colonies are able to build up strongly and store a good surplus. An apiarist here in Gipps once secured 14 tons from 150 colonies. It is difficult to deter-

mine the normal flowering period, for blossoms may be found in the forest throughout the year; but it is usually autumn (and sometimes right through the winter) when the crop is harvested. As the abundant creamy-colored pollen is rich in nitrogenous proteid the colonies develop in a truly wonderful manner, and are quite as strong in midwinter as in midsummer. It is difficult, however, to extract in the cool weather. The rich amber honey—this species yields the palest nectar of any stringy bark—is so dense that it clings to the extractor-can in thick ropes, and effectually prevents the reel revolving. Colonies are thus always in fine order for the red-box flow in early spring. The flavor of the honey is full and rich, so that other honey tastes insipid in comparison. In the drawing, the operculum, or cap, is shown as it clears the expanding stamens. This characteristic is responsible for the name “eucalyptus,” meaning well

covered (from the Greek, *eu*, well, and *kalypto*, I cover). It is a fine tree for builders' woodwork, bridge-beams, railway-sleepers, fence-rails, etc. The bark is stripped off in sheets, and sheds are covered with it, while many apiarists use a small piece for a hive-cover. It was a tree of this species described by Major Shallard, of New South Wales, in *GLEANINGS* recently. The oil dots, although described under red box, are peculiar to the whole family.

RED IRONBARK (*E. SIDEROXYLON*).

Sideros, iron, and *xylon*, wood. This remarkable species is easily distinguished by the bark, which is unlike that of any other tree. It blooms in winter and yields heavily, but the abundant pale nectar is "suspect." Many Australian apiarists associate bad wintering with the ironbark bloom. Whether this is due to the unripe quality of the honey, gathered late, or to some deficiency in the chemical constituents, has not been conclusively demonstrated. The trouble, after all, may be due to some extraneous cause quite distinct from the nectar. It is well known that bees will sometimes fail to visit ironbark, even when the blossom is fairly "dripping" nectar.

The vast majority of eucalypts bear white or cream flowers. There are a few exceptions, and ironbark is one of them, for the flowers are *sometimes* pale pink. The pollen is abundant, and cream in color, and the honey is of good flavor. The timber is red in tint, of great density. It will sink like a stone, and is highly prized for its endurance under stress and strain of all kinds. Ironbark frequents the ranges and flourishes on granite and Devonian rock formations. In this article the possibilities of the eucalypts are only hinted at. The matter is more fully dealt with in my book, now in the publisher's hands, "Australian Honey-plants and Bee-farming."

There is another item of interest—the trees of this family generally hold the buds for about 12 months before blooming. Furthermore, the nomenclature is confounding. Ironbark in Victoria becomes spotted gum, or blue gum in the adjoining state—hence the value of specific names.

Briagolong, Victoria, Aus.

[*Editor's Note.*—This is the second of a series of three articles by Mr. Rayment on certain important pollen and nectar yielding plants of Australia. The concluding article will appear in the next number.]

FINDING THE BEE-TREE

BY E. E. COHEN

While in a reminiscent frame of mind one day lately, my thoughts wandered back to the happenings of my boyhood days, and memory recalled the unfading picture of a most fortunate finding of a monster bee-tree by mere chance.

A skilled bee-hunter had made a long and careful hunt for it. He had located the tree as one of a thick clump of giant hemlocks. He had searched each tree carefully with his still keen eye and spyglass for bees to indicate the entrance, but in vain, and had declared the entrance impossible to find because of the heavy shadows of the dense tops and interlacing boughs.

The scene of my exploit was in Sheldon, in the western part of New York, where my father owned a farm at that time. I was then fifteen.

One warm day in early September, 1859, the thought came to my mind to go out to the woods about a mile and a half away, and look over the big hemlocks for the un-found bee-tree. I started at once, and was soon in the timber where I had seen and followed the old bee-hunter in action. I had noted the trees that he had examined as most likely ones, where the beelines inter-

sected, and these I at once proceeded to inspect closely. I could examine only the west side of each tree because of the approaching sunset. Having examined several trees closely without result I moved on to another, a big fellow about three and a half feet further through, when, presto! looking up some seventy or eighty feet from the ground I saw in a little patch of sunlight a sight that set my nerves tingling, and caused me to throw my hat up in the air and fairly shout to the echo of the woods, "There they are!" and there they were, sure enough, very plainly flitting in and out at the entrance, and many prancing about in all the glee of young bees enjoying a sunshine bath. It was undoubtedly the only time of the day when the sun could shine upon their entrance, hence their gambols that gave them away.

Not much grass grew under my feet on my way home with the glad tidings. With my father and a neighbor to help me the tree was downed early the next day, and the honey secured. After handing out a full supply to the onlookers and to the party who helped us, the net proceeds of extracted honey filled an eight-gallon jar.

A HONEY-SIGN AND WHAT IT SIGNIFIED

BY J. L. GRAFF

I first saw the sign on the telegraph-pole, and from that hunted up the scene of honey-making operations. Robert Kroshel, who owns the outfit, is shown in one of the pictures. He lives in the heart of Chicago, but in the outskirts he rented the wired-in patch of land for five dollars a year. Some little distance away he put up a workshop where he does all of the work incidental to his prairie apiary. He was induced to locate in the vicinity because of the large amount of clover and goldenrod. He has 43 colonies in modern hives. As most apiarists know, last year was a bad one for honey; but he got about 1000 pounds. From some of the colonies in other years he has received as much as 160 pounds each. In winter the hives are well packed, but have no cover other than that shown in the picture.

One of the points that ought not to be overlooked is the utility of the neat little sign on the telegraph-pole. That little board got him customers that took most of his honey, and he sells all of it. The sign is located at the junction of two great highways, and trade came to this apiarist from all directions.

Kroshel has good honey-making stock. His workers are gentle; he makes use of the Italian three-banded queen. This apiarist lives five miles from his apiary; but up to

A sweet and effective by-use of a telegraph-pole. this time no one has ever disturbed it in his absence.

Chicago, Ill.

The apiarist and his apiary.

Pear blight entered the growing tips of the blossom.

PEAR BLIGHT OR FIRE BLIGHT

BY DR. H. A. SURFACE

During the present year there is an unusual manifestation of pear blight or fire blight on apple, pear, and quince trees, from the Mississippi River to the Atlantic Ocean, and from the central portions of Illinois, Indiana, Ohio, and Pennsylvania, southward to Alabama.

This disease makes itself manifest by the death of the leaves, fruit, and bark of the infected apple, pear, and quince trees. It is given various names such as pear blight, fire blight, leaf blight, black blight, black twig, black flag, black leaf, twig blight, canker blight, body blight, bark blight, trunk blight, collar blight, and collar rot. In the last-named form it is by all means the most serious and destructive enemy of our fruit-trees because it works around the collar and roots of the trees, and cannot be headed off nor cured; and when it girdles the tree the latter dies.

This is a bacterial disease that enters through the tips of growing shoots or through blossoms, or through any part of a living leaf, fruit, stem, twig, or bark that may be injured by the puncture of an insect or otherwise that will thus permit the entrance of blight germs. When the germs

once get inside the bark they spread both upward and downward through the cambium or growing layer, and cause the bark to turn black and the wood to become brittle. A blighted twig is often seen broken and hanging downward.

The bacterial germs spread much more rapidly in fruit-trees that have grown rankly. This is doubtless because the wood is more porous and the sap ducts are larger, and admit the passage of the germ more readily in the pores of thickly grown wood. It is conspicuously true that wherever trees are grown in very fertile soil, or have been fertilized with barnyard manure or other nitrogen fertilizer, or have been cultivated considerably to make them grow, there, as a rule, the blight is greatest this year. This means that for these trees that are subject to blight it is best for the orchardist to practice such methods as will reduce the amount of vigorous growth. Among these are light summer pruning, seeding down with a cover crop like crimson clover or rye, avoiding cultivation and nitrogen fertilizers, and applying only fertilizers containing phosphoric acid and potash if any.

Unfortunately the only real remedy that

has been proposed by fruit-growers is to cut out and burn the blighted parts. The cut should be made at least a foot below each of the lowest blighted places. The cut stub should be sterilized by washing with anti-septic material such as lime-sulphur solution or corrosive sublimate in water. It has been proven by experiments that it is not necessary to paint the dry stub with a protecting paint as it will heal, or, in many cases, is as well without it. The infected trimmings should be carried out of the orchard and burned.

The important point to beekeepers is the means by which the germs of blight reach the trees, or, in other words, by which the trees become affected. It has been alleged that bees are responsible for practically all the dissemination of blight germs, while the fact remains that the air is full of such germs, and they may enter the trees at one place as well as another. Ants crawling up and down the trees carry the germs in great numbers. Plant lice or other insects puncture the trees or growing shoots, and the blight germs enter there. Wasps, flies, and various other insects are just as liable to carry the germs of the disease to blossoms as are bees. Even if the bees should be carriers of the germs causing pear blight, the quantity of the disease that the bees

Twigs once in healthy condition.

Pear blight entered the growing tips of the shoot.

carry is very small in comparison with that conveyed by other means; so that if it were possible to stop all the honeybees from carrying pear blight, the dissemination of this disease would be practically as extensive and as speedy as it is at present.

One of the photographs shows blossoms where the blight germs entered and killed the branch. The others show twigs that are dead from blight that were once good and healthy, and in vigorous condition when the blight germs entered and destroyed them. While it may be argued that the bees carry the germs to the blossoms, it cannot be proven that this is not done by other means. Yet, on the other hand, no one would even dare argue that the bees carry the blight germs to the new shoots without blossoms. Therefore, it is unjust to say that wherever a blighted fruit-spur is to be seen, this was due to the activity of the bees any more than to say that the blights of other parts of the tree were due to the same causes.

It is possible that many trees may recover from the blight; but many others will continue to carry it over the winter and from year to year. The best way to get rid of such disease is to be prompt in cutting it out, and cut from six inches to a foot below the lowest blighted area.

Harrisburg, Pa.

THE HOME-BUILT TRACTOR

It may Often be More Efficient than the General-purpose Tractor

BY XENO W. PUTNAM

The gasoline-engine is the wonderful chore-boy of the modern apiary, farm, and household, wherever power is needed in such small quantities or at such irregular and brief intervals of time that steam power would be out of the question, and in places where electricity is not as yet available. It is a specially useful chore-boy in the performance of those tasks wherein the source of power must frequently shift from place to place, perhaps doing some of its work while in the act of shifting.

For the latter purpose it is none the less a legless chore-boy whose usefulness is seriously impaired by its crippled condition. Faithful and powerful as it is when set up and belted to its tasks, in the interval of being conveyed from one to another it becomes a helpless mass of iron that must be wheeled or hauled or carried about by some other source of power, all because even the least of the excellent small power tractors now upon the market are still too heavy, cumbersome, and expensive to be useful in any but the largest apiaries.

In a good many cases the apiarist feels that he is unable to afford more than a single source of power. The gasoline-engine seems perfectly adapted to his varied and intermittent tasks of running a rip-saw, a buzz-saw, planer, lathe, separator, pump, or any of those innumerable tasks which are too quickly over for the employment of steam and too back-breaking to be comfortably done with human muscle. For such work, horses are not very available excepting through tread power. Still, horses are usually required to move even the small power gasoline-engine from place to place occasionally unless we are willing to tote all of the varieties of work by hand or by horse power to the engine. Not every apiarist feels able to keep both a team and an engine. There is always more or less danger of accident, too, in the working of even the steadiest of horses among the gentlest of bees. The power that the apiarist really needs is something that, like the gasoline-engine, can be made to develop from one to three or four horse power at the belt without any preliminaries in getting up steam; a power that is ready for the work whenever the work is ready; something that does not cost much more than a single horse—certainly not more than a team; that can be diverted in a moment from belt to draw-bar usefulness; something that may be tak-

en right among the bees if necessary, and left to stand any place by the hour without any fear of stings or danger of runaways.

It has been recently announced that a new gasoline-tractor is soon to be put upon the market at a cost of about \$200. This, when it comes, will be a godsend to the big apiarist and small farmer. The man with a hundred or so colonies, a big garden, and a few acres of general farm ground, will still in most cases feel compelled to get along piecing out the work of his less expensive little stationary engine by the sweat of his brow. Then there are men who already own a gasoline-engine that is all they can ask at the belt—men who cannot afford two engines, and who do not care to give up the one they have. For all of these men the home-made gasoline-tractor, which can be made at little cost, and out of almost any engine, fills the bill as nothing else can do. All the more is this true because the home-built tractor may be so constructed that it will be specially adapted in every way to apiary work. Home-made tractors are not intended as rivals of the factory-built machines; still, they may often be made to serve out some special mission far better than the general-purpose tractor. They also have the advantage of being available in many apiaries and small farms where even the cheapest of tractors could never be afforded.

In preparing the manuscript of a book upon this subject it was recently necessary for the writer to communicate personally with more than one hundred home-tractor builders, not any two of whose rigs were exactly alike. In fact, the very range and variety was one of the best proofs that the specially constructed tractor can be made that will fit into almost any niche the builder wills. In range of power the engines in these rigs run from one-horse to forty, and in cost from one dollar (outside of the engine and personal work, of course) to \$1260, the latter being designed for special work for which no tractor upon the market served the purpose of the owner so well. Practically every style of engine was utilized—air-cooled, water-cooled, vertical, horizontal, two-cylinder opposed, twin cylinder, single cylinder, and multi-cylinder. In one instance an auto engine was lifted out of a light auto buggy, and, at an expense of less than \$5, mounted in a big harvesting-machine and made to cut 800 acres of wheat

without the aid of a single horse. Another tractor builder has succeeded in constructing a home-made machine with which he does all of his work, light and heavy, on a 200-acre farm without horses. These generalities are enough to prove that no apiarist need feel discouraged or doubt his ultimate success, if his work is well done, no matter what the size and style of his engine or what purpose he requires of his tractor.

A good many home-made tractors have been featured more or less of late in various farm and other papers; but the details of construction have been in nearly every case too meager to be of much assistance in the building of even a similar rig. In this series

of articles it is proposed to tell the "just how" of home-tractor building with as much detail as possible, and still make the directions general enough to apply to all engines. Where necessary, working drawings and illustrations sufficient to make all of the steps plain will be given, particularly in relation to those parts which render a tractor of special value for work among the bees.

Harmansburg, Pa.

[This is the first of a series of three articles by Mr. Putnam, entitled "The Home-made Tractor." The second will be published Sept. 1.—Ed.]

A FEW REPORTS ON THE VALUE OF ASTER HONEY FOR WINTER STORES

Frequent Flights Make Wintering on Fall Honey Successful

BY SARAH A. GRAVES

My bees are in double-walled hives, packed with sawdust. I use one chaff division-board and tray of shavings for winter. They are quite well protected on the north and west by outbuildings, trees, and shrubs.

We have a large yield of goldenrod and aster honey. I have found the bees late in the fall working on asters a mile from home. They worked on asters last fall till killing frosts, and went into winter quarters very strong in bees and stores. They had a good flight Dec. 7. Then followed a month of very severe weather, said to have been the coldest December in this section for forty years. On Jan. 7 they had another good flight, another one early in February, and frequent ones from then on. The strongest colonies lost scarcely a handful of bees, judging from entrance indications, and the others very few.

March 24 was the first day on which I saw pollen carried into the hives. On May 5, the first suitable day on which I was at liberty to give the hives a thorough examination and clip queens, I found two colonies with six frames of brood, three with seven, two with eight, two with nine, and one with ten. The last one had several sealed queen-cells, and two others had cells started. I found an unusual quantity of drone brood. Combs that were nearly perfect last season had drone-cells built in every conceivable place, even a few cells right in the middle of the frame.

Last season one cutting of cells in my best colonies stopped swarming for the rest of the season. This year I am cutting cells

every week, and yet I have already had four swarms, and the rest of the ten are going to follow suit. I can't understand why they have developed such a swarming mania, because, with the exception of a day now and then, the spring has been unusually cold, with more than our ordinary amount of rain. They have all commenced work in the supers.

I have one queen which is a living witness of how much a bee can endure. In June, 1913, I attempted to cage this queen, then about a month old. With the blundering awkwardness of a beginner I pressed her against the comb, injuring her diagonally across the upper part of her abdomen. I thought she would surely die very soon, or that the bees would kill such a cripple. But she is living yet, and has proved my best queen. Her hive is always running over with bees, though she has no more brood than many of the others. Her bees proved good honey-gatherers and showed no inclination to swarm till this spring. They swarmed twice, and returned while I was away.

When I had a chance to examine the hive I found the bees worrying and pulling at the queen. I located her by her squealing. I at once put the frame in another hive. The bees drove her out of the entrance on the grass as fast as I could open the hive and put her in, till I fastened them in. In a few hours they had quieted down and she was back on the comb busy laying. She was not failing, for her hive was full of brood in all stages. She now has all the brood the nucleus can care for. By keep-

ing her in a nucleus I hope to keep her living all this season.

HONEY REFRIGERATED.

Last June I sold a woman a section of fruit-bloom honey. In September I made another sale to her. At this time she told me she had just taken the other honey out of her refrigerator, where she had kept it all summer. She did not notice until she

took it out that the carton read *not* to keep in a refrigerator. She said the honey was uninjured, for all she could see. But she said she wouldn't risk any more.

Three Rivers, Mass.

[Evidently she had a good refrigerator in which the ventilation was so ample that the air was dry. The dampness in the average refrigerator is what injures honey.—Ed.]

SUCCESSFUL WINTERING ON ASTER HONEY

BY J. F. KIGHT

As is generally known, the honey crop in Indiana for 1914 was a failure. Honey became so scarce in my twenty-five colonies in August that I bought 300 lbs. of granulated sugar at 8 cents, and commenced to feed about one quart to the colonies daily outdoors. Soon the queens had most brood-combs full of eggs and larvæ. By the middle of September the hives were boiling over with young bees; but I do not believe there was 50 lbs. of honey in all the twenty-five colonies. Fortunately I yet had some of my eight-cent sugar left when the white aster came in full bloom. To my surprise the bees refused any more sugar syrup, preferring the aster.

As each colony was unusually strong in young bees, what they did to that aster nectar was a sight. They filled every available cell, crowding the queens until, by the time the flow ceased, each hive seemed as heavy as that much lead. I do not believe there was a pound of any kind of honey in my whole apiary except white aster. In early November it turned cold, and my bees

were packed in leaves with the single telescope cover until they were ready for almost any kind of winter weather.

My fear as to the results of the aster honey gave me a chill. I thought I would have only beeless hives full of aster honey in the spring. To increase this fear, when my bees did not get a cleansing flight from late in November to February 11, I felt sure I would have no bees left.

To my surprise, on Feb. 11 each colony showed signs of life, and all had a cleansing flight. My bees came through the long and cold winter in better condition than I have ever had them in my thirty years of experience in bee culture. I did not lose a single colony, but had four weak ones queenless on April 10.

To sum up, I firmly believe if bees are plentiful in the hive, can have plenty of time to ripen the honey, and are well protected on the summer stands, there need be no fear from aster honey.

Indianapolis, Ind.

DRY LOCATIONS DIMINISH WINTER LOSSES

BY W. C. FLEMING

Bees filled up heavily last October on aster honey, and I was very much pleased, as I had never had any trouble wintering on this honey, neither had I ever heard of any objections to aster honey as a winter food in this latitude. Bees get a flight almost every week during the winter months.

I have my bees in two yards, one at home and the other a few miles east of home.

My home yard of eighty-five colonies is located in a rather thick pine grove with heavy woods on the north and west. Little sunshine or wind gets to them, and the ground is rather low and wet.

In this yard my loss was rather heavy for North Carolina. I lost seven outright, and more than a dozen were very weak and al-

most worthless when spring came. They showed spots along the front of the hive, telling plainly that dysentery was the trouble. My other yard east of home wintered perfectly, not a single loss, nor could I detect any sign of dysentery.

Both yards wintered on aster honey wholly, and all hives were well filled in both yards. Now for the difference. My home yard where the loss occurred is heavily shaded, and, on low ground, became very damp. The other yard where there was no loss stands out in the open where all the sunshine and wind can get to them. Hence they wintered in a dryer condition.

Greensboro, N. C.

THE PERENNIAL WHITE ASTER IN WINTER STORES

BY D. W. TAYLOR

For seven or eight years I have had from six to twenty colonies in Louisa County, Virginia. This is in the Piedmont region, about 500 feet above the sea—a poor location for spring honey, as white clover usually fails, but with large quantities of aster and a good deal of goldenrod. The aster is the variety with white petals and yellow center—the kind I see everywhere in the East, a perennial growing well on sour land, about two feet high on poor land and four feet on good land.

At the same time as the aster, there is available a large quantity of goldenrod of the short-branch headed variety which my bees seldom or never touch. The tall-growing single-spike headed variety is fairly abundant, and they work on it freely.

Usually my bees are quite light by September, but during the aster and goldenrod

season they work diligently and the hives get very heavy.

I winter on the summer stands, simply contracting the entrance and putting a super full of leaves on top of the hive. I have had single and double Danzenbaker hives and ten-frame hives.

My winter stores are always mainly aster, I feel sure, because the bees work very strongly on it, and when it is coming in one can smell the odor a hundred yards away.

I have never had the slightest trouble with wintering—never lost a colony by dysentery or anything of that nature. Once or twice I have failed to winter a colony or two, but am sure that they were not queen-right to start the winter. Of course, in my locality bees are able to fly a number of times during the winter.

Washington, D. C.

ASTER PUTS THE WIN IN WINTER

BY C. F. BUCHER

I always look to the asters to build up my colonies for winter. They have sometimes built up so strongly from aster that I have had a few swarms. I have seen four or five frames of brood the first of October, and every one knows what that means—a pile of young bees for winter.

I have wintered from 20 to 40 colonies, and have not lost half a dozen in sixteen years. One winter in this time they went to bed November 10 and never got up until March 5. I began to feel a little uneasy about them. Of the thirty that I wintered that year only one was dead, and I got the largest crop of honey the season following that I ever harvested.

I never saw any aster honey amber in color

except when it was mixed with goldenrod. It is seldom that one gets aster honey in its pure state; but last year and four years ago I had no honey any lighter in color than that from the aster, nor any heavier in body. It was so thick that it was very hard to cut out of the sections on a cold morning, and when the weather grows cold one can hardly cut it at all.

Last year we sold 500 sections and 200 pounds of extracted in less than ten days, all from aster, and it was so light that it looked like white-clover honey.

In this locality we have the white aster. J. L. Byer says the aster with him is blue or purple.

Underwood, Ind.

WHERE ASTER WINTERS WELL

BY RAWLEIGH THOMPSON

Our bees came through the winter in excellent condition with a few exceptions. Out of forty colonies two are weak and two died—due to failure of queens, I think. Both were young queens, but they did not breed up last fall as did the others. On account of the prolonged illness and recent death of my aged parents, with whom my son and myself were living, our bees received little attention in the fall and spring.

For winter stores the brood-frames were

almost solid with aster honey, gathered mostly from a weed that our Pennsylvania Germans call "Basum-reisich." It begins to bloom here about the middle of September, and continues until severe frost kills the plant. Sometimes the flow from this weed is abundant, last fall our bees making considerable surplus.

Not for the purpose of getting into print, but in view of what the editor, Dr. Miller, J. L. Byer, *et al.*, have to say about aster

honey. I may add that in this locality we depend on the late fall honey to carry our bees over the winter. Generally speaking, during July and August bees cannot find

enough to make a living. As a rule hives are very light by the time the fall flow begins. Sometimes it is necessary to feed.

Littlestown, Pa.

WINTERING BEES ON PEPPERMINT CANDY

BY W. H. WEBB

Our bees wintered on aster honey, for this is our only fall flow here. I never have any trouble with dysentery. When we put our bees up in the fall we put a box of peppermint stick candy over the brood-frames and cover the candy with a piece of cloth and an empty super filled with tow sacks. The bees seem to eat the candy in preference to the honey.

I have been using peppermint candy several years for wintering, and it has proved successful. I don't know what the

candy contains that prevents dysentery or pollen-clogging. I believe it is better than the other candy. I should be glad if other beekeepers would try this method and find out what the results will be.

We went in for the winter last fall with fifty colonies, and we lost four stands on account of the mice cutting them down. It was our fault by not closing the entrance. All the rest came through in good condition this spring.

Roanoke, Va.

ASTER HONEY NOT NECESSARILY FATAL

BY ARTHUR C. MILLER

Aster honey does not cause trouble when a stock has lots of young bees *and brood* late in the fall. But it and sugar syrup given late both are disastrous. I saw a number of good stocks dead on syrup fed *after* the first or second severe frost. Bees were all worn out. Hereabouts feeding is usually deferred until after frost. It is all right to a limit when the stock has brood

and young bees, but I am now satisfied that other practices will be better—for instance, giving combs of sealed stores or candy.

I believe it will prove a gain to have a few stocks in summer kept busy filling combs with syrup purposely for fall use. I have to use a boiled syrup with tartaric acid in it, but even so it will pay.

Providence, R. I.

WINTER STORES IN JUNE

BY WILLIAM CRAIG

Almost every one differs in his way of feeding bees. I am using a ten-frame Langstroth hive. During the white-clover or basswood flow I take off as many supers filled, and all capped over, as I have hives of bees. The supers are just the same size as the hive-body. The super contains ten frames, the same as the body below. I set these away in a room in the house, and keep them until about Oct. 1, or until brood-rearing has ceased.

I now load on the wheelbarrow one of these supers that I have stored away, and begin at No. 1. I set the hive containing the bees to one side, and set the hive filled with honey on the stand. I take out one of the frames that was filled with honey, and leave it at the house to be extracted.

I now take a frame from the hive that I set aside, and shake the bees all down in front of the hive that rests on the stand, and continue to do so until the bees are all

shaken off. This hive now contains nine frames all filled and sealed over. The nine frames are spread to an equal width, and a section tacked on top to keep them from shifting around. If I wish to move them around after the bees have gone in, every colony is fixed just the same.

I then take the frames that contained the bees and extract the honey out of them. Some of the hives would have scarcely any honey in them, while some of them would have had plenty to winter on, but I don't like to take any chance. Some may think this is a costly way to winter bees; but I think, taking all things into consideration, it is just as cheap as some of the other ways of feeding. I have done much feeding in my time and it has always looked to me as though the bees were wearing themselves out considerably during the process of feeding.

Aitkin, Minn.

Heads of Grain from Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

Boss, I always hear you talkin' 'bout de queen. Where am de King?

Kansas as a Bee State

I have been a reader of GLEANINGS for two or three years, but do not recall in that time ever having seen any mention or communication of or from Kansas. While this state is not so old as California, Ohio, New York, and other states in bee culture, yet, as in many other respects, "Kansas is to be reckoned with." I have no statistics before me; but for more than twenty years past a considerable quantity of honey has been gathered, especially in the western half of the state. In fact, while there is more or less Colorado honey shipped in, yet a considerable shipment each year goes out of Kansas.

Garden City is one of the best local centers of the bee industry in the state. Within a radius of ten miles of Garden City there are perhaps nearly two thousand colonies at this time. The swarming season began about the first of June, and is now practically closed. The increase has been quite large this season.

Our best and most productive honey-plants are alfalfa and sweet clover. Both produce a fine white honey, and of the finest of flavor.

Yes, Kansas as a honey-producing state in the future will, in our judgment, make rapid strides. If this little note finds its way to the readers of GLEANINGS, KANSAS may be heard from again.

The writer handles some 40 colonies of bees as a matter of recreation, as it were, from the more confining duties of office work.

Garden City, Kan.

B. F. STOCKS.

[There has been not a little said in these columns concerning beekeeping in Kansas, especially

in regard to sweet clover, which has begun to make its way on the uplands where alfalfa could not be profitably grown. In late years alfalfa and sweet clover both have been making rapid headway over the state, and naturally with them go the keeping of bees. It is but fair to say, however, that conditions in and about Garden City are probably more favorable than in most portions of the state.—ED.]

Where the Moth does Not Corrupt

Under "Care of Comb Honey," page 11, Jan. 1, Doolittle advises storing honey at a temperature of 80 to 95 F. He says, "The supers of sections should be separated so that the warm air can circulate freely all through."

Now, he undoubtedly meant that this wide-open exposure of the supers to get all possible ventilation should be done in a moth-proof room, as otherwise the wax-moth, ever on the alert, would soon create havoc with the exposed sweets. But he does not say so, and I fear that, unless warned, some of the uninitiated may not think of this danger, and suffer thereby.

My own plan for keeping comb honey in hot weather that I have found very successful and inexpensive is this: I pile up the supers of honey anywhere in the honey-house, with a double thickness of burlap between the supers, supplemented with a sheet or two of newspaper over the burlap. The newspaper takes the drip, if any, from the super above, and obviates a "mess." I am always careful to pile up supers of the same size together, that no little space be left open anywhere that would admit that very sleek and slippery hunter Mrs. Moth.

From time to time I examine my supers of honey thus stored for a stray worm or two that may have hatched from eggs deposited while the super was on the hive.

Manawa, Wis.

E. E. COLEN.

[In most well-regulated apiaries in the North, especially where pure Italians largely predominate, the bee-moth is almost entirely unknown. Supers of comb honey under these conditions can be stored as Mr. Doolittle directs. Where, however, black bees are pretty common, we may also expect bee-moth. This is particularly true in many parts of the South. It is then that the supers should be protected.—ED.]

46 Swarms from 29 Colonies

We have had a fairly good season, and the bees are now working lively, but my crop of honey will be very much reduced on account of excessive swarming. I have had 46 swarms from 29 colonies. Last year I had only four from 31 colonies, which, as you will see, was quite a difference from this year's swarming. I have even had a second swarm from one of this year's swarms hived in a ten-frame chaff hive—something that I never had before—and the said hive is now literally boiling with bees again. One colony that did not swarm this year is now working in the fifth super. This is the best that I have ever seen for building up colonies. We are now having a grand rain—in fact, we have had plenty of rain for the past two months and a half; and if the rains continue I may yet have a record year notwithstanding so much swarming.

Glyndon, Md., July 15. WALTER E. ATKINSON.

Kerosene to Stop Robbing

We noticed on page 618, 1914, Mr. Plummer's plan to stop robbing. We tried a similar plan a few weeks ago in our queen-rearing yard. Excessive rains daily for three weeks left all colonies and

nuclei on the verge of starvation, and they had to be fed until favorable weather permitted the bees to gather nectar.

All queen-rearing nuclei and some of the stronger colonies were being robbed as soon as we put on the feeders. After spraying kerosene on the alighting-boards and entrances, leaving enough space unsprayed for the bees to get in and out, we inserted a Porter bee-escape in the entrance of one nucleus without spraying kerosene. In less than 24 hours nearly every robber bee was caught in that one nucleus, and they stayed there, too, defending the new home from the few stray robbers that were left. All colonies and nuclei that were sprayed with kerosene were not bothered, the robbers just hovering around a minute or so.

The odor from the kerosene kept the bees in the hive for a time, but they seemed to defend themselves much better, probably on account of the number of robbers being diminished. No need to use hay or grass. We simply reduced each entrance to one bee-space. We have used the above plan several times since, and it proved successful in each instance.

New Albany, Ind. WALKER & MARZIAN APIARIES.

[Kerosene has been mentioned before as a preventive of robbing. We should, however, be a little careful about relying on it. Where robbing is badly under way it would probably not have very much effect. From reading your letter we are more inclined to think that your bee-escape robber-trap caught all the robbers and therefore stopped the robbing, and not the kerosene, for the simple reason that there were no robbers at large to annoy the nuclei.]

One of the most reliable and effective means to stop robbing is to use the robber-trap. Usually not more than one or two colonies are involved. Remove the robbed hive and put the robber-trap in its place. In fifteen minutes all will be as quiet as if nothing had happened. We would place more reliance on the robber-trap than on kerosene, although we know the bees do not like the smell of it; and a little sprinkling at the entrance has a tendency to drive away intruders, while it does not necessarily keep out the inmates of the hive.—ED.]

A Virgin Queen Leading a Swarm Out and a Laying Queen Remaining in the Hive.

Something occurred in my apiary that I never heard of before. I put a queen-cell in one last week and looked for her yesterday. She was laying well, when in about three hours a fine swarm came out. I wondered what was the cause. After the swarm had settled I looked in the hive for queen-cells and found the laying queen in the hive. I looked on the swarm and I found a virgin queen which I caged. In a few minutes the swarm came back to the hive.

I was always under the impression that the laying queen always led the swarm out. What was the cause of the two queens in the hive, one laying and virgin leading the swarm out?

Roanoke, Va. HENRY S. BOHON.

[There must have been another cell in the hive that you overlooked when you supplied the colony with a queen-cell. The one you furnished was probably older, and hence hatched out first. The younger cell, shortly after, hatched its virgin; and when it went out to mate the bees went with her, the laying queen remaining in the hive. As a general rule, however, the laying queen would have gone out with the virgin also.]

It is not true that the old queen is always the one that goes with the prime swarm. When cells are due to hatch, the swarm will usually issue, and with it the laying queen. A second swarm might have several virgins, provided they were in the hive; and a third swarm might have also one or

more virgins from cells hatched later. There is no invariable rule about swarming.—ED.]

A Late Indiana Report

I have kept bees for twenty years, and have never seen a year here like this. It was so cold and wet in early spring the bees missed the early flow, so they have been on the edge of starvation ever since. I have been feeding twenty-eight colonies for six weeks. The young larvae starved in colonies extra strong.

Our main flow is from the bluevine, which is just coming into bloom. But it is raining almost every day, washing all the nectar from the bloom. White clover looks promising for next year; but it seems to bear no nectar, neither does the alfalfa in this locality.

I must mention a large colony taken from a tree Nov. 9, 1914. I did not get the comb nor the honey—only the bees. They were hived in a Danzenbaker super containing cull sections of honey gathered from white asters, half of it unsealed. The bees wintered nicely out of doors and built up earlier in the spring than the rest of the colonies. Do you think the fence separators were of any benefit in wintering? I am inclined to think that if we would remove two combs from our brood-chambers and place a slatted fence between each comb for winter it would be better for localities where dysentery causes trouble.

Bloomfield, Ind., July 10. JOHN M. WOOD.

[There is probably no merit in fence separators for wintering, beyond the fact that they separate combs a little further apart, thus giving a little better clustering room between the combs. It was formerly the common practice to separate the combs a little further apart just before packing for winter; but that practice has practically disappeared. The tendency nowadays is to let the colony alone. Too much tinkering with nature is sometimes disastrous.—ED.]

Hitting the Vital Spot

I have read in GLEANINGS and other papers that bees cannot sting each other except in certain places. I am sending two bees. Upon examination you will find that one of them has stung the other in the middle or second joint of the front leg.

A friend brought the bees to me, and said

that he saw the bee sting the other, and that it killed it almost instantly.

Bristol, Tenn.

A. H. GOODMAN.

The bee on the left was killed by a sting in the second joint of the front leg.

Sweet Clover, 70 Acres; Buckwheat, 20 Acres

We have 12 acres of sweet clover this year, and we sowed 70 acres this spring.

I am mostly an orchardist, but I take care of our bees. I think horticulture along beekeeping lines is bound to be developed to some extent in a practical way some time. At any rate, I am quite interested in some honey-plants. We had ten acres of Japanese buckwheat last fall. We got no surplus, but all frames were filled. It seemed not to yield honey very well. We got 25 bushels per acre, and 90 cts. per bushel, which made it our best crop last year. We have just sowed 20 acres this summer.

Danville, Iowa, July 7. WENDELL P. WILLIAMS.

A. I. Root

OUR HOMES

Editor

Apply thy heart unto instruction, and thine ears to the words of knowledge.—PROV. 23:12.

Buy the truth, and sell it not; also wisdom, and instruction, and understanding.—PROV. 23:23.

Mr. James G. Gray, who was for many years foreman of our manufacturing establishment, died early on the morning of July 15; and I think it may be interesting to the readers of GLEANINGS to go over with me the events of a busy life that ended only in death in the 85th year of Mr. Gray's age.

Our readers will pardon me *once more*, if, in order to make this a continuous story, I repeat, or partially repeat, some things that have been given already on these pages. I was perhaps eight or nine years old when Mr. Gray came to Mogadore, Summit Co., Ohio, to teach penmanship and ornamental drawing. I think he was about eighteen at that time. His wonderful penmanship created a stir in our little town, and his ornamental drawings *were* a wonder. In fact, people would have been tempted to say *he* did not do it himself were it not for the fact that he would take almost any pen or any paper, and astonish the natives in just a few minutes. I have forgotten what the tuition was for learning to write; but the ornamental drawing cost, if I remember correctly, about \$25. He soon had quite a class in penmanship, and those who took lessons would, if still alive, show it in their hand-writing up to this day. He was so well liked, in fact, that when winter came so that it was too cold for him to travel easily, he was engaged to teach the Mogadore high school; and, of course, the same beautiful penmanship was taught in the common school. At that time I had just got hold of the book "Conversations on Chemistry," and also Parker's Philosophy. This was before I went to Wellsville, as mentioned in a former paper. One evening after school our teacher said something like this:

"Amos, you have some home-made apparatus with which you are making experiments, I gather from what you have said in your recitations. Now, if you do not object I will go over this evening to look over your apparatus; and if I can help you in your experiments I shall be glad to do so."

Let me now digress a little. There were just two in our family of seven who seemed to have a particular liking for books. One of them was myself and the other was a sister some older than I. In fact, she was so diligent in her studies that a small district school out in the country was offered

her, when she was only fifteen (and wearing short dresses); and so far as I can recall she taught it very acceptably.

Well, of course I had my rude home-made apparatus and chemicals all ready for Mr. Gray when he came to make the visit; but something on a different line caught his attention before he gave me much notice. It was the bright young schoolma'am; and I remember telling my mother, almost dolefully, that I did not believe Mr. Gray cared so much about chemistry after all, for he kept talking to the young schoolma'am. By and by, however, he gave me his whole attention. I had been trying to make a pneumatic trough for handling gases; but my arrangement leaked in spite of glue, melted rosin, etc. In some way I had found out that Mr. Gray was a carpenter as well as a writing-teacher and schoolteacher. If I remember correctly, his parents sent him to Oberlin to school, but later on they found he was spending more time in a *chair-factory* near by than he was in school; but when they discovered he had become quite an expert carpenter, even at that early age, they did not feel so much troubled about it.* My father was also a carpenter, as I have told you, and had a chest of tools. When Mr. Gray looked at my leaky trough I said to my teacher, "Do you suppose you can make a wooden box like this, and make joints so tight it will not leak, even if there were no cement on it?"

At this he glanced toward my father, with a quizzical look on his face, and they discussed the problem of making a wooden box that would not leak. My father opened his tool-chest, and Mr. Gray selected a smoothing-plane, sharpened it up according to his notion, and made the box with a shelf to hold my glass bottles and jars; and when I poured it full of water it did not leak a drop. How many carpenters of the present day are equal to such a problem? A year or two afterward, when Mr. Gray married the young schoolma'am, there happened to be an "electricity show" at the same hour of the night the wedding occurred. When my mother and sisters said I must stay and be present at the wedding I became rebellious. The idea of anything preventing me from attending an "electricity show!" I think they changed the time of the wedding so as to come a little earlier or later. About this time an older brother of mine was plan-

* This was before the world thought of carpentry and growing corn and potatoes as one of the branches of a common-school education.

ning to attend a dancing-school. Mother and father, of course, objected; but he quoted this, that, and the other who were going to that school, and there seemed to be no way of settling the matter until the son-in-law said, "I think I can persuade Marshall to give up the dancing-school. I will give him lessons in drawing." In a little while my brother was so much taken up with his progress in writing, and later in ornamental pen-drawing, that he forgot all about the dancing-school. In fact, when he was a boy in his teens he went out teaching penmanship, and gained quite a little money thereby.

From first to last Mr. Gray has been a friend and helper in the Root family. In fact, he accomplished many things besides what I have narrated that no one else could have brought about. When I became interested in poultry he advised me, in order to find out whether it paid or not, and how much it paid, to keep double-entry book-keeping. Make the chickens debtor to everything purchased for them, and give them credit for every egg laid. I was delighted with this orderly way of doing business, and I think the biddies must have been "delighted" also; for before the year was ended everything had gone over to one side of the ledger. The chickens paid all expenses, paid for themselves, and paid for their poultry-house and for their poultry-yard.

When I commenced "lecturing," Mr. Gray invited me to come out to the "Black Swamp" in the western part of Ohio (where he was running a sawmill), and *educate* the people round about in chemistry and electricity. I have alluded to my ups and downs in my lecturing-tours. When it came toward winter Mr. Gray suggested that I should stop traveling during the winter months, and teach a school in their neighborhood. Let me digress right here to mention an incident in Mr. Gray's school-teaching:

In our Mogadore high school, at the time of his visit, there had been much trouble with incompetent teachers. They could not preserve order. If the master called one of the big boys to come up on the floor he would not go; and when the master tried to enforce his command by catching hold of the unruly pupil the boy would hang on to the desk until the master would have to give up. One day Mr. Gray called on a good-sized boy to step out on the floor because of disobeying some of the rules of the school. When the boy did not come, Mr. Gray took him by the collar and pulled a little. As the boy seemed to be pretty well anchored,

as usual, Mr. Gray seemed to hesitate, and then there was a titter among the rest of the pupils, all thinking the new teacher was "up a stump," like his predecessor. But all at once something happened; and it was done so quickly that it seemed like a sleight-of-hand performance. Before anybody knew how it came about, Thomas was on his back in the middle of the floor, and piteously promising to be good and behave himself if given another chance. By the way, for Thomas, who was always so neatly dressed, and had his hair combed so nicely, it was a rather severe shock to find himself in such disorder on that old schoolroom floor, none too clean at best. From that time forward Thomas was one of the best and most obedient boys in the school. When he went away, Thomas said he was not only the best teacher, but that he had learned more from Mr. Gray than from any other teacher in his whole life. Here was a practical illustration of the old proverb, "Foolishness is bound up in the heart of a child: but the rod shall drive it from him."

Well, now, let us go back to the Black Swamp. When my brother-in-law urged me to give up lecturing and go to teaching school I objected; but when he told me that the weather here in northern Ohio would make me trouble, and be bad for my health at my early age, I listened. He said, "Amos, if you just drop lecturing until spring, your school money will furnish you means in the spring to go on lecturing for *quite a long while*. You see you will have quite a little money laid up for a rainy day, etc.*"

To make this story brief, when I first planned our hive factory, in 1878, and was thinking about a brick building near the railroad, my first thought was that Mr. Gray could better plan the building and take hold of the manufacturing business than anybody else I knew of in the world. At that time he was in northern Michigan; but I solicited him to move back to Medina and take charge. For many years he was general foreman. He not only superintended the construction of our first brick struc-

* When he applied to the directors for the school out in the Black Swamp, and they learned my age, they made the objection that I was too young. The boys in that particular school had turned the teacher out of doors several winters in the past. Mr. Gray assured them that there would be no such thing as putting me out of doors, even if I was but eighteen years old; and, in fact, some of the big boys did undertake it; but I have told you in a previous Home paper that their plans did not work. I do not know but I told the boys they might carry out my body, but not while there was any life remaining. But there was not any "dead body" in the fracas; and after the directors met to consider matters they hired me for another month longer just because I refused to be dethroned.

ture,* but planned building after building as the years passed and the business increased; and he gave up his place only when he had become too old to assume so much responsibility; and till within only a few months back, with only slight intervals, he has been connected with our institution more or less ever since. Even during the past winter he has usually put in half a day's work in the factory, employed wherever nice mechanical woodwork was needed. He has always been a very busy man. Carpentry and fine woodwork seems to have been his special forte. He has built many dwellings, several automobile garages, and his wonderful skill in ornamenting various structures seems to have been his peculiar gift since the time when he did such wonderful work with his pen when but a boy.

Now for my closing incident. All through the life of our departed relative he was a remarkably *busy man*. He could never be idle a moment; and besides that he had a peculiar and wonderful skill to take hold of and improve everything he touched. Between 65 and 70 years ago it was quite the fashion to make pictures and mottoes on perforated paper. By using different kinds of bright-colored yarn, which I believe they called "crewel," at that time, some beautiful needlework was done by the women folks, and it was really very pretty. Mr. Gray happened to be in to see my sister one summer evening, and found her at work on some perforated paper. He picked up a scrap or strip of the paper that had been cut off; and, selecting his variously colored crewels, he worked out in a little time, in beautiful, colored ornamental letters the following:

Thine till the heart in death is cold.

He gave it to my sister, and she put it away, evidently considering it too sacred to be shown to anybody, unless, perhaps, to her mother. But I happened to go into her room one day, and before I could find what I wanted I came across this piece of ornamental lettering. It just hit my boyish fancy. There was a little golden-haired girl who lived near us, and I often used to see

*Those who have visited our plant here in Medina will have noticed the beehive on the front of the first brick structure. Above the hive are the words "In God we trust." It was at Mr. Gray's suggestion that a hive carved out of a block of sandstone should adorn the front. There was some talk about a motto to be placed above it, something like

"How doth the busy little bee
Improve each shining hour," etc.

But I finally decided to have cut in the sandstone above the hive, the words "In God we trust." Mr. Gray drew the letters on the stone for the mason to cut out, and I hope the managers of this industry for generations to come may, at least once in a while, glance up to that inscription and manage this business in a way that all the world may see that we are living up to our profession.

her as she went down to the spring at the foot of the hill to get a pail of water. I made up my mind that if my sister would *lend* me that piece of work I would make one like it or at least *try* to make one like it (in due course of time—of course not right away), for the girl who used to come down the hill swinging her sun bonnet in one hand while she carried the tin pail in the other.* But my day dreams were suddenly interrupted by the entrance of my sister who gave me a scolding for invading her treasures without permission. When my mother interceded, however, I was permitted to try to make a copy of the precious piece of work; but my copy never came anywhere near the original.

When I this morning saw that lifeless form cold in death, memory ran hastily back to the time when the bright young teacher, full of life and energy, patiently wrought out that gift especially for his betrothed, "Thine till the heart in death is cold."

Mr. Gray united with the Congregational church when a boy in his teens, and was still a member at the time of his death.

THE GREAT ARMY OF UNEMPLOYED; GOD'S KINGDOM IS COMING.

I was particularly impressed with it this morning while reading an article in July *Successful Farming*, of Des Moines, Iowa, entitled "Our Government: what it is Doing, and How." I earnestly wish that every one of you would send and get the July issue of that paper and read that one article. It was a happy surprise to me to learn that our Government has not only taken care of the unemployed, but is sending to farmers all over the United States exactly the men needed as far as possible; and it does this, too, without a cent of pay on the part of the unfortunate man who is without work or the farmer who wants help. Those who apply for employment are put through an examination to see what they are good for, and to see if they really *will* work. As an illustration:

A farmer from away out west wrote and told just what sort of man he wanted. The Department wrote him that they had a man who would suit him exactly, except that he was a Russian and could not speak a word of English. He wrote back, "Send him on." When the farmer got to the train the Russian said "Good morning" to him, and, to his further surprise, he could talk quite a little English. How did it happen? Why, the Government gave him

*Of course this was long before I first saw Mrs. Root.

a little book with red-ink phrases such as he would most need to use in English, and an explanation in his own tongue. He studied his little "dictionary" all the way on the long trip, probably talked with the passengers as well as he could, and that is how it came about. Well, now, here is the best part of the little story:

The farmer who agreed to pay him a certain price raised his pay the first month; more the second month, and so on.

HIGH-PRESSURE GARDENING

SPINELESS CACTUS—WHAT OF THE FUTURE?

I suppose I shall meet with some criticism because I think best to give so much space to the spineless cactus, especially since the Department of Agriculture and the experiment station of Florida do not at present give very encouraging reports in regard to it. When I first saw Kidder's circular and price list in regard to the spineless cactus I decided some of the statements should be received with caution; and while I feel to a certain extent the same way yet, I think he and others like him often do great service to agriculture. His circular and his letters suggest a certain comicality that is contagious. As an illustration I submit below a portion of a letter just received; and I have taken the liberty of giving the letter just as he wrote it, "short cuts" in spelling, and all.

My dear old friend:—Apologizing for the long delay, I have been greatly overburdened with bizness and correspondence. I thank you for your kind letters and interest, and copy of GLEANINGS. I have enjoyed looking it thru instead of reading it thru, Eckawz I don't have time to read anything thru lately, and my table is piled hi with unlookt-thru books, magazines, and papers. Yet I enclose \$2.00 check, for which please send me GLEANINGS beginning with the August number and also a Luther household grinder. My family will enjoy it anyway, and may be I will have a little more leisure time too to look it thru more carefully. My eye cant the letter from your good kind Christian friend Henry Borchers, of Laredo, Texas. My! I wish my naborhood was full of such men as that. I also appreciate the joke about the reward your wife gave you for sharpening up her paring-knife, and I presume my wife will reward me quite as handsomely—she frequently does.

Yes, I saw the criticism on spineless cactus in the papers you mentioned, and it caused a perfect avalanche of inquiries to slide on to me, and also the loss of hundreds of dollars' worth of orders. I have, therefore, prepared an article on spineless cactus for publication, which you are at liberty to quote or publish in whole or in part if you wish.

I certainly shall be delighted to have you call and see me at any time it is convenient for you to do so; but I am afraid I cannot supply you with any cactus fruit yet awhile, at least not until late next fall, as I am constantly cutting my plants back to fill orders.

Why, it was worth a whole lot to have these two good men brought together. His learning to speak English impressed me vividly with my experience in learning to speak Spanish when down in Cuba.

Now send for that article and read it through. It will increase your faith in our Government, and increase your faith in the fact of what I am telling you, that God's kingdom is coming.

I don't think I have made any extravagant statements in my circulars which are not true. I have quoted some quite extravagant-sounding statements from other people, however, and presume those are the ones to which you refer. Yes, certain varieties grow better on rich soil than on poor soil. I have never written any different opinion, but you seem to have misunderstood me there.

Monticello, Fla., July 29.

SAMUEL KIDDER.

What gave me enthusiasm down in Florida was the astonishing growth of the cactus in just a few days. Well, right here in Medina I am having the same experience. A couple of pictures on another page will show you the growth made in just nine days; and the funny thing about it is that we have had rains about every other day (or oftener), while the cactus made this growth in a heavy clay soil.

Mr. Kidder's booklet, which I advise all to get and read (as well as look at the half-tone pictures), suggests that the cactus plants will take the place of the silo in Florida and other southern states. You can plant it any day in the year, and harvest it any day in the year—that is, the kind for forage. I think one of the government reports gave as a reason why it could not be of any great value was that it is "almost all water." Here is a clipping from Kidder's circular in regard to the matter:

The erroneous statement that there is "too much water" in spineless cactus to make it a desirable and practical food, "especially in Florida where water is so plentiful" (ha! ha! ha! it makes me grin to think of it), was recently made by a hitherto supposed-to-be-wise old guy. He evidently must have been dozing for the moment or else forgot the days of not so long ago when mother first saw the pictures of tomatoes in the catalog and wanted to try some; but father said, "No, I've read in the newspapers that those things are poison, and will give you a cancer if you eat them. Besides, the professors say they are of no value, as they are almost all water, anyway."

Suppose they are almost all water. Below is a table that friend Kidder submits of

* The expression, "where water is so plentiful," gave me a good hearty laugh, and I laugh again as I think of it. "Plentiful"—I should think so. When it is raining close to a foot in 24 hours it well might be called "plentiful."

THE CACTUS SLAB MENTIONED ON PAGE 646 OF THE LAST ISSUE OF GLEANINGS.

This slab was planted in our Medina garden about July 1. The picture on the left hand was taken July 26, and the picture on the right was taken just nine days after. With the first picture you will notice some corn in the background. The next time, in order to show the new slabs (or leaves) to better advantage, I held a white sheet back of the plant. This astonishing growth was made in common clay soil; and I think it demonstrates beyond question the wonderful growth this plant *may* make under favorable conditions. We expect to give another picture in our next issue.

some other things that are "almost all water."

Milk	87.5	Oranges	87
Grapes	87	Apples	83
Spinach	90	Pineapple	89
Lettuce	94	Asparagus	94
Tomatoes	96	Squash	95
Strawberry	90	Pumpkin	94
Peaches	69	Cornstalks	80

And while we are discussing this, let me mention that, years ago, when we marketed Jersey Wakefield cabbage every day, on purpose to use up trimmings from the cabbage I got some little pigs. Now, these pigs did not have a thing—not even a bucket of water—in addition to the cabbage leaves. We almost covered the little fellows up with cabbage, and the pigs made a tremendous growth. An account of it is given in our book "What to Do," etc. You see the cabbage was provided fresh every day in the week; and when we grow cactus for cattle, horses, pigs, or chickens it *also* can be furnished fresh every day in the year.

CACTUS FRUIT, QUANTITY AND QUALITY, ETC.

I have seen just one real good tuna (cactus fruit). I found it in the road near Sebastopol, Cal., where some one had dropped it, evidently by careless handling, and it was near the Burbank ranch. My own cactus plants, from slabs which were put out in the spring of 1911, gave me 48 tunas that were the size of medium oranges. I saw larger ones in Bur-

bank's gardens at Santa Rosa. The quality was good; but the taste was different, somewhat, from anything we were used to eating, so we did not become enthusiastic over them, while at the same time we liked them fairly well. Here we have so much good fruit that we are thoroughly accustomed to eating that *we are poor judges of a fruit of entirely different character*. The one tuna I spoke of was very ripe, a little wilted, and tasted as good as a prime fig or nice berry jam; *in fact, sweet and delicious*; however, I look upon the tuna as a better feed for fattening hogs than for human consumption. The cactus plants, *I am told*, become full bearing when about five years old.

At Mr. McCubbin's, over at Reedley, the three acres of cactus of three years' growth have not produced any large crop, but they have borne an increasing crop each year. He has about 20 plants five or six years old that he has pruned severely each year for cuttings that give a good quantity of fruit in spite of the severe pruning, since only last year's slabs will produce fruit this year, etc. All varieties (120 of them) bear fruit, but only a few are good for human consumption. You can get the whole history of the opuntia from the U. S. bulletin, Department of Agriculture, Washington.

Selma, Cal., July 8.

O. S. DAVIS.

Here is something further from friend Woodberry relating to the matter:

Mr. Root:—Regarding the fruit of the cactus, I fear it would be impossible for me to acquire a liking for it; but the Mexicans esteem it quite highly. I have not noticed it on the fruit-stands, yet it may be on sale in some sections of Los Angeles. I will send you some ripe fruit later on, and you can judge for yourself.

Glendale, Cal., July 11.

G. B. WOODBERRY.

THE ST. REGIS RASPBERRY.

Just after I got back from Florida (I think it was about May 10) I sent to W. N. Scarff, New Carlisle, Ohio, 25 cents for three plants of the St. Regis raspberry. I was induced to do this because the card declared they would bear fruit the first season. It is now July 29, or about 80 days since the little plants were put out in good ground. By the way, instead of sending me *three* plants for the 25 cents, as advertised, I received *six*. They were only a few inches long, and it was some days before the entire six really started to grow. Perhaps it was June 1 before they really got to going. Well, it has been one of my happy surprises to see them put out bloom, and now every one of the six little bushes is pretty well loaded with berries; and they are about the largest red raspberry I ever saw. I have been disappointed so many times in new things extravagantly written up that I do not know but I was beginning to lose faith. But here is a beautiful fruit right before my eyes, only 80 days from planting. I wrote Mr. Scarff how well pleased I was with the new raspberry, and he replies as follows:

We are very glad you are pleased with the St. Regis. We have just finished picking a fine crop of berries from plants of the St. Regis set last spring. It is certainly a fine berry. They will rest up now for a short time, but will again begin to bear about Sept. 1 and continue until Oct. 15 to 20.

New Carlisle, O., July 26. W. N. SCARFF.

Perhaps I should mention the fact that one reason for my good success is that the six plants stand where there was a small poultry-yard for two or three years. Red raspberries are selling now in our market for 20 cents a quart. This is a day and age in which we want returns quick. Do you know of any other fruit or berry where you can reap a harvest in 80 days from the time of planting?

SWEET CLOVER; THE GOOD THINGS ABOUT IT NOT YET ALL TOLD.

We clip the following from the *National Stockman and Farmer*:

EXPERIENCE WITH SWEET CLOVER.

So much has been written both for and against sweet clover, also of its uses, that it would seem that all has been told.

Such is not half the case. Its evils are none that I know of, and I have known it for many years. It may become a pest when it runs wild, but a blessed pest it is—more blessed than bluegrass or any other plant I know of that has the ability to run wild and be useful. As a soil-builder it has no equal. More than fifty years ago the Panhandle railroad was graded along by Raccoon Station, and a deep fill had to be made to the approach to the trestle over Raccoon Creek. To get dirt enough for the deep fill they stripped off all the soil down to the solid rock, this stripped area being about five acres

in extent. A school-house was built on this bare rock, as many readers of *The Stockman* may remember. In some unknown way the seeds of sweet clover got into the cracks of this rock. This was about thirty years ago. The rock being exposed began to soften on the surface, and the sweet clover spread over the entire area, as well as all around it. I was along the road about ten years after the sweet clover came. The schoolhouse was gone, but the growth of sweet clover was simply immense. Then I began to dig in the newly made soil, which was fully five inches deep, and the rotten rock under the soil was deeper, and was filled with the clover roots that were fast breaking up the underlying rock and making it into new soil.

It is said that sweet clover must have an abundance of lime; but this rock did not have much lime in it, as it is what is known as the Connellsville sandstone.

In many other places I have seen fine sweet clover growing where no limestone was to be found, yet it does far better in a good limestone soil, or a soil that has been well supplied with lime.

The good qualities and many valuable uses of sweet clover are too numerous to mention. Its nutritive qualities are superior to alfalfa, and it is eaten just as greedily after stock of all kinds has learned to like it, which is not very long. Its earliness exceeds all other plants, even rye. This day (April 10) the young sweet clover is over two inches high, and the frost has not been out of the ground over one week, and you just ought to see the chickens eating it. They pasture right on it all summer and fall, as it stays green till killed by hard freezing; then the seeds begin to fall, and the hens just scratch and pick up seeds from dawn till dark. I am safe in saying that an acre of sweet clover will produce more chicken feed from the seeds than an acre of wheat or corn, and fowls will pasture on it all the growing season, and still be making the ground richer. At the same time the bloom will produce from three to five dollars' worth of the finest honey.

Sweet clover is also a great sub-soiler and an underdrainer. I have measured roots that were an inch and a quarter in diameter, and often from three to five feet or more in length. These long roots are of untold economic value in their process of plowing, draining, and fertilizing the sub-soil.

At Downeyville, in Butler County, Pa., there was a swamp of two or three acres along the creek. After the railroad went through, sweet clover got a hold in it, and in five years that swamp was drained; the roots had pierced the subsoil and let the water down into a lower stratum.

There are three species of sweet clover on the market. *Melilotus alba* is the largest and best. It has white blossoms. *Melilotus indica* is small, lives only one summer, and is of very little value east of California. It has yellow blooms.

Jefferson County, Pa.

GEORGE HOUGH.

Permit me to call attention to the statement that it furnishes the best of feed quicker than any other clover or any other plant grown on the farm. In corroboration of this I may say that just across the street from our home is a field of sweet clover on this 13th day of May, knee-high, and growing as thick as it will stand. The seed was sown with oats a year ago, and near this sweet-clover field is a field of crimson clover and also rye; but the sweet clover certainly furnished good feed away ahead of any of the others. I was particularly interested also in the statement about an acre of sweet clover for chicken feed. It seems to me that

statement is at least exaggerated unless we take into consideration its value as green feed as well as the value of the seed for chickens.

THE DASHEEN AND ITS PRESENT STANDING.

I have before expressed surprise that none of our northern seedsmen, who are supposed to be on the lookout for everything new pertaining to the garden, have never made any mention of the dasheen. Just now, however, the Henry Field Co., of Shenandoah, Iowa, has given it a place. Below is something clipped from the *Country Gentleman* in regard to it:

PROGRESS WITH THE DASHEEN.

Ever since the Federal Division of Foreign Seed and Plant Introduction began its experiments with the dasheen this West Indian crop has proved itself well worth care. In 1909 the Department recorded a South Carolina planting of dasheens that yielded at the rate of 400 bushels to the acre. Since then from less than five acres on the Department's testing grounds at Brooksville, Florida, 1400 bushels of dasheens have been harvested. From other plantings in Florida and Louisiana as much as twenty-two pounds of dasheens has been harvested from single hills.

In addition to the Florida, Louisiana, and Carolina crops, the dasheen has been successfully grown near Norfolk, Virginia; in Southern California, and near Ray, Arizona. It promises well for use in irrigated sections of the semi-arid Southwest.

It would seem that the Department's success with dasheen plantings fits in admirably with the new Southern campaign for crop diversification. Not only does the dasheen promise well as a market crop once the public generally has recognized its merits, but in the meantime it is capable of furnishing food for home consumption. Its food value is higher than that of the potato. The dasheen contains less water than the potato, and about fifty per cent more protein and fifty per cent more starch. The flavor of the dasheen is decidedly richer and more tempting than that of the potato.

Robert A. Young, of the Department, says that in more ways than one the dasheen outdoes the potato.

"It can be grown as a summer crop in a region where the potato must be grown almost entirely as a spring crop," he argues, "for it ripens its tubers in October and furnishes them for the table at a season when northern-grown potatoes have to be shipped in.

"The young leaves, properly cooked, can be substituted for spinach. The branched shoots, obtained by forcing dasheen corms in the dark, constitute an entirely new product. The nutty flavor of the tubers gives them a peculiar palatability."

The larger tubers are ground into flour, which is used for soups and gruels, and is mixed with wheat or rye flour to make griddlecakes, biscuits, and bread.

At present the dasheen appears to be no more difficult to keep in storage than the sweet potato, but will usually keep well if stored in a dry place at a temperature of about sixty degrees Fahrenheit.

We are also told that the Department of Agriculture has recently issued another circular concerning it. Although the dasheen is still mostly confined to the South, yet I might say we are now growing our third crop here in northern Ohio, and I feel more and more satisfied that it can be grown

profitably all over our northern states; and it will ultimately prove to be one of our most nourishing and toothsome vegetables.

DASHEEN IN ALABAMA A SUCCESS, ETC.

Last year the two bulbs of dasheens that we received from you were planted and cared for carefully and this spring we had over one hundred bulbs to set out, besides some to give to our schoolchildren and neighbors to try. We are in the backwoods here, and people are much interested in the modern method of handling bees. Some time I will write you of the work we are trying to do along the line of missionary work, as I know you will be interested. Your last magazine has just arrived, and wife immediately laid aside all work till she had glanced over your article.

Semmes, Ala., May 18.

C. D. GRIFFIN.

STRIPED SQUASH-BUGS—A SURE REMEDY FOR THEM.

As a rule, chickens and a garden do not go very well together unless one or both are inside of a chicken-proof inclosure. But there are exceptions. Listen to the good brother below:

Friend Root:—I have just been reading in GLEANINGS of your troubles with the striped cucumber-bug. Prior to this year I have tried about all the remedies ever suggested, and failed generally. This year, just as the melons and cucumbers were coming up, I took an old hen and about twenty day-old chicks, put the hen in a coop, let the chicks all run at large in the patch, and in a few days the bugs came "a plenty;" and what those chicks did for them was "a plenty" also. And grow? I never saw chicks do better. When they began to scratch I moved them out and put in younger ones. This scheme worked for me, and I pass it along for what it is worth. I might say, with things in this shape I slept all right at night and went to church on Sunday.

CYRUS H. CLINE.

Mt. Solon, Va., July 23.

Many thanks, friend C. If I hadn't been stupid I should have thought of the hen and chickens before; but knowing that chickens will not eat the common potato-beetle I did not feel sure that they would eat the striped squash-bugs. The next point is, to be sure to have the chickens on hand when needed. I have been telling you that when you set a hen you should plant some radish seed so as to have it ready for greens. Now we shall have to say, also, when you plant your squashes you should set a hen or two hens, and then you can all go to church. This reminds me that another brother had trouble with the bugs as well as myself. Read what he says:

Mr. Root:—For a number of years I have used a powder made of equal parts of slacked (dog) lime and stovewood ashes. After being dusted the plants look a little dull and dry, but the powder soon scales off, and the plants look healthier, brighter, and get a stronger growth than before. I have used this powder to drive away yellow striped bugs from pumpkin plants, melons, etc., with good success, and prefer it to any other remedy. Try it on one plant, and I am sure you will use it on all you have.

Elgin, Iowa.

POULTRY DEPARTMENT

GROWING YOUR OWN CHICKEN FEED INSTEAD OF BUYING IT, ETC.

I remember once hearing a small boy say to a merchant, while standing in his store and looking at the fine array of goods, something like this:

"Mr. Brown, if you did not have to pay anything for your goods, wouldn't it be fun to keep store?"

Well, I have been many times thinking what fun it would be to keep chickens if we did not have to buy food for them; and while off on the island of Osprey, I had a neighbor who had a small flock of chickens which they did not feed a thing. The poultry had the run of the whole island, and my neighbor got quite a few eggs. Of course he did not have very many chickens—perhaps fifteen or twenty.

Well, since wheat has been away up out of sight I have been wondering if I could not grow feterita and other things so as to avoid buying expensive grain down in my Florida home. Of course we do grow our own chicken feed here in Ohio—that is, we grow both corn and wheat to sell. I might slip some down to our Florida home every fall; but the transportation would make it cost more than to buy it there at the great warehouses. Well, now, here is a clipping from the *Florida Grower* that hits the very point we are discussing.

DADE CITY, FLA., July 25, 1915.—In reading the letters published in the *Grower* I see numerous inquiries as to what can be grown here in South Florida for chicken feed. Now, I am in the poultry business, and finding my profits badly cut by the greatly increased cost of western grain since the beginning of the European war, I determined this spring to raise all the feed I could myself. I have a farm of thirty-two acres, and "board my chickens at home" as far as possible.

I planted cassava, corn, Egyptian wheat, chufas, chicken corn, Spanish peanuts, cowpeas, feterita, millet, and sunflowers. Also have collards growing on low ground for greens. At the present I have ripe cowpeas, sunflowers, chicken corn, and Egyptian wheat in abundance for my poultry, and consequently have been able to cut off store feed entirely, which in these days of soaring prices is truly an extremely pleasant thing to do. I expect to feed wholly on home-grown stuff till frost comes. After that I will have some feed and some I shall have to buy. I believe the various new sorghum family grains are likely to prove a wonderful help to southern poultrymen; for although they seem so perfectly adapted to the arid section, growing and producing crops with almost no rain at all, yet they seem to take just as kindly to our numerous and generous summer showers. My feterita, planted, May 28, is now, July 20, about seven feet high, and heading out finely. It is an entirely new crop to me; but I am told that western people who have tried it thoroughly consider it a good substitute for wheat. One nice thing about it is its remarkably rapid growth.

Egyptian wheat planted at the same time as the

feterita is not heading yet, but I have some planted earlier with ripe heads a foot or more in length. It looks very nice indeed, and the chickens eat it greedily. Another thing I am trying this summer is Sudan grass. It is designed for forage rather than for grain. I am much pleased with it also, and, as I said before, it certainly looks as if these new sorghums would prove a boon to the South.—C. H. T.

Please notice his feterita has grown seven feet high, and was heading out after it had been planted only 53 days. As Dade City is a little further north than Bradentown, and away from the water, they usually have frost more or less. In our Bradentown garden we usually have no frost so as to interfere with feterita or anything else. But it makes a very slow growth during the colder months.

Without question it is possible to grow your own chicken feed as I have suggested above; but if you have to hire help to grow your stuff it may transpire that it will be cheaper to buy corn and wheat shipped in than to grow some substitute as suggested. Each person will have to figure this out for himself. If you like the fun of growing stuff as well as keeping chickens, and have nothing else to do, very likely you can so manage as to pay out no money for your chickens; and so all you get for your eggs and fowls will be your pay for your labor.

I suggest the above is a good scheme for an old man like myself. Grow your crop with your hand cultivator, such as we have been talking about; and it is a comparatively easy matter to do this in our friable Florida soil.

A good friend, after writing me a long letter, suggests that perhaps I had better have a chunk of that "maple sugar" before I attempt to read it all and give him an answer; and *you* may need some of that same maple sugar to go along with that cultivator in growing the feterita to feed the chickens.

FETERITA IN VERMONT.

Will you please send me a few feterita seed to experiment with? We are so far north that I think if it will ripen in 60 days we need it much. Some years in 90 days corn will ripen. A grain that will stand dry weather and make good is what we want here.

WALTER F. WHIPPLE.

Newport Center, Vt., July 29.

My good friend, unless you have sixty days of warm dry weather I hardly think you will get any feterita to mature. While it grows tremendously during the hottest part of the season, it makes a very slow growth when we have cold weather, especially if there are cold rains such as we had last winter in Florida. You can, however, grow green feed safely before frost.

Cleanings in Bee Culture

Southern Headquarters for Italian Queens

Photo of W. D. Achord of Fitzpatrick, Ala., with helpers, also his queen-rearing yard. Queen-house and residence in background. With six experienced men, and 600 mating-boxes, also 700 full colonies of pure Italian bees, we are able to give good queens and prompt service. Untested queens, 1 to 11. 50 cts. each; 12 and more, 45 cts. each. Tested, \$1.00 each. No disease. Pure mating and safe delivery I guarantee.

W. D. ACHORD, Fitzpatrick, Alabama

More than Enough Honey to Pay the Freight on Carloads of Bees from the South

OUR Virginia and Texas carloads of bees gathered more than enough honey to pay the freight and other expenses on them up here, but not enough to pay the entire cost of them. About July 1 it looked as if we would have to feed the 600 colonies; but the hives are full, and some colonies are four and five stories high. After all, we do not think much of the proposition of moving bees two or three thousand miles in carlots. The railroads are exacting too big a toll to make it pay. It is much cheaper to "make" bees out of cheap honey or sugar syrup right at one's own home, and at the same time avoid the great risks of extremely hot weather or wrecks. The "made" bees will be any strain desired—not the mixed bloods that one finds when he goes after them. We solicit articles from those who have made colonies by feeding sugar syrup, or cheap honey for increase.

Automobiles — 75 per cent of Them in the Hands of Farmers

OUR old friend the *Practical Farmer*, which, a few years ago, was opposed to the use of automobiles on the common highways, must have modified its opinion somewhat; at all events, it is authority for the statement that 72 per cent of the machines in use are owned by farmers. Farmers would, of course, have to use the common highways. Our esteemed contemporary (one of the best papers in all the world) must, therefore, approve of farmers purchasing machines and using the same roads used by horse-drawn vehicles. What is good for the farmer is good for the beekeeper.

Automobiles are wonderful time-savers; and when one buys a moderate-priced ma-

chine the upkeep and depreciation are not nearly as great as is the case with a horse and wagon, and the cost per mile only half as much, and, moreover, the machine has nearly ten times the range.

Drone-laying Queen Brood Sometimes a Stinking Mess

A COUPLE of months ago we had a scare at our home yard. We found several frames of brood that were a stinking mess. The capped cells had the characteristic perforated capping; and while the dead matter did not rope it seemed to be a case either of European foul brood or sac brood. The possibility of the former gave us a great deal of uneasiness until we learned it was drone brood. Our Mr. Mell Pritchard in charge of our queen-rearing then recalled that we had had a number of cases of this kind in past years from drone-laying queens. We sent a sample of the brood, to make sure, to Dr. E. F. Phillips, of the Department of Agriculture, for examination. The report came back, "No disease." We merely mention this that others may be advised who find laying-worker brood; and if it occurs in considerable quantity during late June or July, much of it may be dead or stinking.

Honey-crop Conditions and Prices

IN most and practically all localities the clover yield is over. The flow, more or less intermittent in most of the clover belt, continued up to the 15th of August; in other words, clover has continued to yield nectar at least a month later than usual. Apparently the aggregate yield this year of clover and some basswood is very much heavier than a year ago, and prices will run from 15 to 25 per cent lower, depending on the grade. There probably is not much more comb honey produced this year than last. While a year ago there was a larger percentage of comb to the extracted, this year the reverse is true. The intermittent yield of nectar, interspersed with cold rainy wet weather was very unfavorable for the pro-

duction of comb; and the result was, the aggregate yield is very much lighter than it would have been, but about the same as last year. Taking it all in all, comb honey will rule about the same as a year ago.

The Californians estimate that their crop will be 40 per cent normal. Last year it was about 50 per cent; but a large amount of California honey was held over. Last year's crop and this year's crop combined has tended to reduce the price of California honey anywhere from 15 to 25 per cent. The lower grades of amber are selling very slowly. Before the great war, large quantities of amber went to the European markets. This outlet has been shut off for over a year. Undoubtedly a large part of this has found its way into the manufacturing trade because it is cheaper than invert sugar, and is always better, because it has flavor.

In Imperial Valley, according to J. W. George, one of the largest producers there, the crop has been the poorest of any year since bees were introduced there. It will not run over 40 lbs. per colony.

The Colorado crop will be light, especially in the eastern part. In other portions of the alfalfa regions the yield will be nearly normal.

Taking it all in all, prices on all grades of honey will be lower this year than last, except comb honey, which will be about the same as last year.

Cost of Operating Built-over Automobiles, Touring-cars, and Trucks

A CERTAIN man once went to the editor of a newspaper, complaining that said editor had made the announcement that the complainant was dead. "Sir," said he, "I will have you to understand that I am not dead. I am very much alive."

The editor replied, "A newspaper never makes any mistakes, and therefore never retracts. If we said you were dead you were dead; but if you have come to life again we shall be glad to publish the fact, but that is all we can or will do."

Whatever may be newspaper policy or etiquette, GLEANINGS does not believe in that policy. While we have not made any statement to the effect that somebody was dead, we do know that some things ought to be dead. On page 609 of our issue for August 1 we stated that one could become the owner of an automobile truck that would cost him but a small sum of money by putting a truck body on a second-hand touring-car. Sometimes that may be true, and sometimes it isn't.

It is said that an open confession is good for the soul. It may be good for other people who may be inclined to follow the editor's well-meant but bad advice. Well, we found that the repairs on this second-hand auto, if continued at the present rate, would make the machine cost nearly as much as a first-class new automobile truck or a first-class new touring-car.

In buying a second-hand machine it is not always possible for one to know how much repairs will be required in the near future to keep the thing going, how much time there will be lost on the road, and cost of breakdowns. Some second-hand automobiles are dear at any price, while others are good bargains. Much will depend on the party who owned or operated them while they were passing from the new to the second-hand stage. At all events, our rebuilt auto "auto" be dead because it is costing us altogether too much to maintain, and we are beginning to fear that it would be cheaper for us to make it real dead with a sledge-hammer* and sell the junk to the dealer. A half-dead auto is a nuisance.

Wilmon Newell of Texas Accepts a State Position in Florida

WILMON NEWELL, who has been doing such good work as state entomologist and apiculturist at College Station, Texas, has resigned to accept the position of state plant commissioner of Florida. He is one of the best bee entomologists in the whole United States. Any state that can get him is fortunate. He will make good anywhere. His successor has not yet been decided on.

Mr. Newell took an active interest in beekeeping in Texas. He issued a number of bulletins on various matters connected with the industry that had more than ordinary merit. He kept a large number of bees himself, and this season sold to the A. I. Root Co. a carload of bees. He therefore knows the practical as well as the scientific side of the bee-question. What will be a loss for Texas will be Florida's gain; but, unfortunately for American apiculture, Mr. Newell probably will not be in position where he can do as much with bees and beekeeping as he formerly did. He will, however, have a wide field in studying a large number of plants and trees that yield honey in the state where he is going. It is to be hoped he will not wholly lose his interest in things apicultural, for the beekeepers of the country would be sorry to lose his valuable help in research work. His work was

* Some autos ought to be dead, that's sure.

so good that Uncle Sam, as we happen to know, came very near at one time making a bid for his services.

Our Sweet-clover Cover in Last Issue

WE failed to state editorially in our issue for August 15 that the cover picture for that issue was made from a small vest-pocket kodak, 0 size, by Miss Mary Porter, daughter of Mr. W. L. Porter, formerly of Denver, but now of Caldwell, Idaho. Miss Porter, a schoolteacher and an ardent beekeeper herself, was in attendance at the National convention of beekeepers last winter. She showed us the picture she had taken of a very rank growth of sweet clover along one of the irrigating ditches of Idaho, and wondered what kind of a cover picture it would make. It seems that at the time it was taken she was standing on the bridge, for the railing shows in the foreground.

The growth of sweet clover is sometimes enormous, but it is seen at its best along some of the irrigating-ditches of the West. The picture is a fair sample.

By the way, we would not dare to show Miss Porter's picture for fear some half a dozen young men would write her proposing marriage. We have in times past shown the faces of a number of single good-looking young women beekeepers. In several instances they have been surprised, amused, or shocked by several proposals of marriage. So far as we know these pretentious youths have been turned down flat or ignored.

The Great War and the Wet Season

EVERY now and then we hear statements to the effect that the great war is responsible for the almost continuous rains this season; and even a prominent lecturer on our Chautauqua course went so far as to state that the "scientists" of the country "agreed" that the heavy cannonading in Europe was responsible for the large amount of precipitation this year. The facts are, the "scientists" of the country do not hold that view. The United States Weather Bureau has repeatedly said there is no relation between heavy explosions and rainfall. Some years ago France wasted thousands upon thousands of dollars in experiments to test out this very thing. Similar tests were made in Texas, but results were always negative.

The claim that rains have followed great battles is not always true; and when rains have happened it has been simply a coincidence. If the great war is responsible for

the floods and rains in many localities in the northern parts of the United States *this year*, why did not that same great war do the same *last summer*? Why did it not make it rain in Texas and Florida this year? On the contrary, there was a long drouth in both places.

There have been seasons of almost continuous rains before without wars big or little anywhere. This talk about "scientists agreeing" that severe concussions induced by cannonading bring on precipitation is nonsense. It is true we can lay a great many things to the war, but it is not responsible for everything.

Those Large Quadruple Winter Cases or Tenement Hives; Have They Made Good?

WE should be glad to get reports from those who have tried out the large winter cases that hold four colonies on the tenement plan. Some call them Holtermann winter cases; others the quadruple winter case, and still others tenement hives. As a matter of fact, Mr. Holtermann did not invent the case bearing his name, and does not claim that he did; but he does use a simple construction, one of the best, and hence the name. There are other cases built on the same principle, one used by Mr. A. C. Ames, of Peninsula, Ohio.

Whatever the modification, the principle is much the same—using four colonies (back and sides together) to utilize the heat of each cluster, leaving only one side and one end and the top of the hive to be protected by packing and the outside case. For cold climates, and for excessively cold winters in milder climates the quadruple winter case has so far scored exceedingly well. But it is no cheaper than a double-walled packed hive. The amount of lumber that these cases require is just as much, and the labor of packing and unpacking in the fall and spring is vastly more. On the other hand it is argued that, if bees do winter better on the tenement plan, we can afford to pay more, both in labor and material.

Who invented those big tenement cases? We do not know, and it is not important; but our readers will find the tenement chaff hive described in the early volumes of GLEANINGS and illustrated in the frontispiece in early editions of our A B C and X Y Z of Bee Culture, in the early '80's. We used one for several years, and invariably it gave us good results. In the early days the veteran, E. France, used it, and later his son, Mr. N. E. France, for many

years foul-brood inspector of Wisconsin, and still later his sons have been using the principle.

Why, then, was the principle dropped by so many beekeepers and retained by so few? We do not know, unless it was that these big hives were heavy and unwieldy, because they involved extra labor in packing, and because they were not portable. The modern tenement is made in sections. It can be taken down and moved at any time.

Is the Advice to Put Comb Honey in a Refrigerator Always Wrong? A Challenge from Dr. Miller

FOR years the recommendation has gone out without a challenge, to store honey in a warm dry room—never in a cellar nor in a refrigerator. Any sane beekeeper who would challenge that statement has nerve. In a recent letter Dr. Miller refers to pages 659, 670, and 682 of our last issue. Then he says, "I want to ask you to put some honey in a refrigerator and then report whether it gets wetter or dryer." While he does not say in so many words what his experience is, the inference is that it does not get wetter, and that its quality improves, because cold honey becomes thick and waxy rather than thin, warm, and tasteless.

In some cellars and in some refrigerators the air is almost dry. In others the reverse is true. Moreover, no matter how dry either may be, the tendency to granulate is hastened materially. While that does no harm particularly for extracted, yet every time the granulated article is reliquefied some of the flavor is lost. Granulated comb honey no one wants except the Jews, who use it at certain seasons in their religious festivals in a preparation that makes use of both honey and wax. In any market granulated comb honey has lost a third of its value, and very often it will not sell at even the price of extracted.

We would agree with Dr. Miller's implied statement that both comb and extracted comb honey are improved if they are put into a refrigerator for a few hours before going to the table. They are improved in that they become thick and waxy. There is nothing finer to eat than a good grade of table extracted honey that has been placed in a window in hard freezing weather for a few hours before it goes on to the table. It becomes so thick and stiff it is almost impossible to dip it up with a spoon. If ever there was a food "fit for the gods" it is *cold* honey.

Thank you, Dr. Miller, for bringing this point up. Of course you and all others would agree that the advice to keep either comb or extracted honey in a dry warm place of even temperature for *storage* purposes is entirely correct.

Crop Reports in Ontario, Canada

THE Ontario Beekeepers' Association of Canada is to be congratulated on the excellent work it is doing in securing crop reports from its members. (See the summary in last issue.) The credit for this work is largely due to Mr. Pettit, the secretary. The association is doing more thorough and better work than is being done in any portion of the United States or elsewhere in Canada. In the last report received, dated August 5, 1910, 7 colonies were reported, comprising a large area of the province. From this number of colonies there was secured up to that date 1,053,328 lbs., making an average per colony of 55.1 lbs. In going down the list, some counties report as high as 100 lbs. each per colony. And then we find 93, 107, 85, 78, 77, then down as low as 14, 15, and 19 lbs. per colony, making an average of 55.1 as stated. If Ontario has had as much rain as Michigan, New York, and Wisconsin, and the Government maps show that it has had nearly as much, it will doubtless still have a great deal of clover in bloom. The presumption is that all these averages per colony, as well as the general average, will go even higher.

If we had had as thorough work done as this in every state in the Union, we should be able to know by the first of August, at least, the amount of honey in sight, and the price it would bring to move the crop.

THE EFFECT OF THE GREAT WAR ON THE PRICE OF HONEY.

The prediction is made for Ontario that, while the crop is average and the "quality excellent," the "buying power of the public is below the average." This is doubtless due to the great war, which probably will produce a little more depression in Canada than in the United States. But the war certainly has affected the buying power of the people on *this* side of the line, and this, of course, will have a tendency to depress prices on food products that are not staple like meat, butter, milk, and the grains. Honey, while a concentrated food, is still regarded more in the line of a luxury than a staple. The public is inclined to regard as a luxury any non-essential when times

are hard. The facts are, honey, for the money, stands at the very top of the list of foods as an energy-producer.

=====

Can Good Queens be Raised and Sold for Fifty Cents?

WE have received a number of letters endorsing our editorial on p. 573, July 15, entitled "Complaints against certain Dealers; when Patience Ceases to be a Virtue." Among the number is Kenneth Hawkins, of Plainfield, Ill. He writes:

"I wish to speak a word in approbation of your stand. Any advertiser who will not give an iron-clad guarantee, and stand by it until his patrons are satisfied, does not deserve any business from beekeepers."

Again, on this subject, Mr. J. Ivan Banks, of Dowelltown, Tenn., who, to use the parlance of the day, has been "stung" by some queen-breeders, writes:

I read with interest Mr. Doolittle's article on rearing good queens, page 573, July 15; also your editorial, page 608, current issue—"Complaints against Certain Advertisers; when Patience Ceases to be a Virtue," and now wish to ask the question, Can good queens be reared at a profit at 50 cts. and even less? According to my experience they can not. I find that at \$7.00 per dozen there is very little profit in queen-rearing. I think if breeders would ask a fair price for queens, and then aim to rear better queens, there would be fewer complaints. Dowelltown, Tenn., Aug. 9. J. IVAN BANKS.

In answer to Mr. Banks' question, we may say that the demand for queens comes and goes. Sometimes the breeder may have more orders than he can handle promptly. At other times he may have a big stock. If he has his work systematized, weather conditions not being too unfavorable, he will be having a certain weekly output of queens. There will be times when he will have one or two hundred on hand. In order to make room for his virgins still coming on he can afford at such times to sell fifty or a hundred laying queens in the hives at a very low price. He had better get 50 cents a queen, perhaps, than to lose his virgins and, worse yet, throw his queen-rearing operations all out of gear. In times like this he can afford to sell queens at a low price in order to reduce his stock; but as a regular proposition, week in and week out, he cannot afford to sell them at 50 cents apiece, pay the cost of advertising, the cost of labor, the cost of select breeders, cost of feeding sugar syrup, cost of replacing queens that arrive dead, time in answering correspondents, and cost of bad weather when his matings will be low, or heavy windstorms when sometimes he will lose a half or two-thirds of all his good drones. It costs something to turn out a first-class

product; and as a general thing the price of a good laying queen from a good breeder will circle around a dollar, the price varying according to the season and the supply on hand.

We agree with our friend Banks that it will be far better to put the price up, and with it the quality, rather than to put it down and sell any old thing in order to take care of the trade. There are some queen-breeders who, we are told, make it a regular practice to take cells of *any kind* from *any* colony, and sell such product to their customers. Such people usually furnish queens at low prices, and the quality is correspondingly low as a result.

=====

Cost of Letting Colonies Get near the Verge of Starvation; the Value of Young Queens in the Fall

MR. J. L. BYER in his department in this issue says very truly that when a colony has got down to just a few cells of honey it will be almost sure to destroy a great deal of young brood by eating up the larval food. Instinct teaches that it will be folly to raise more consumers, and therefore natural prudence would suggest a saving in the living force through rigid economy until the time comes for honey to come in.

But the real point of Mr. Byer's caution is not that young brood is destroyed, but rather that the *beekeeper himself* should not let the bees get to the danger-point. It is exceedingly wasteful to let unsealed brood die for want of food. If a colony is to winter well it must have a large stock of *young* bees to go into winter quarters. To stop brood-rearing now by carelessness is inexcusable.

But this naturally brings up the question that, during August and September in the North, brood-rearing (under ordinary conditions) will automatically cease, even though there are plenty of stores in the hive. If the queen is a year or two old she will let up in her egg-laying soon after the harvest, and may not commence again until a late flow of fall asters causes another flow. It may then be too late to get much of a stock of young bees.

It is right here that a *young* queen is far more profitable than an old one. Given sufficient stores, a young queen will keep right on laying through summer and until late in the fall, and she will stock that hive up with young blood that can stand the rigors of winter. An old queen that has exhausted herself in the early part of the season will usually stop laying when the main hon-

ey-flow ceases, whether the hive has plenty of honey or not. Sometimes the introduction of a young queen in late summer or fall means the saving of a whole colony of bees by next spring; and even if an old queen with her colony survives, the colony may be so weak that it will not be able to do very much by the time the harvest comes on.

The Genesis of Honey Extractors and Extracted Honey in the United States; Extracted Honey at 25 Cents a Pound

IN this issue, pages 719, 720, is shown a picture of an old honey-extractor made by Captain Sanders as far back as 1875, or forty years ago. This machine is placed on exhibition at the A. I. Root Company's exhibit at the San Diego exposition. Captain Sanders knew nothing of A. I. Root's first honey-extractor, built in 1867; and yet, strangely enough, the machines are alike in principle, with precisely the same gearing.

Seeing that machine at San Diego brought up early memories. Well do we remember A. I. Root's original machine. It consisted of a milk-can that was stationary, with inside revolving reel and baskets to hold the combs. The reel was geared to a part of an old apple-paring machine mounted on a wooden cross-arm. This outfit was the forerunner of the Novice honey-extractor brought out in 1873, for A. I. Root did not begin to manufacture and sell supplies until some time after he built his honey-extractor and made his first hive.

Before A. I. Root put his geared machine in a stationary can on the market Mr. J. L. Peabody brought out the first extractor that was ever made and sold. This was in 1869. Later Gray and Winder and R. R. Murphy brought out their machines. The Peabody consisted of a revolving can without gearing. Referring to this, Mr. J. L. Peabody, the inventor, who was at the National convention at Denver last winter, was generous enough to say that Bro. A. I. Root's *geared machine* with a *stationary can* was so much superior to his that he took it off the market.

It was this old original machine that A. I. Root built that took his first thousand pounds of extracted honey. It so fired up his enthusiasm that he turned his attention more and more to bees, and less and less to his jewelry business, for at that time he made silver chains and rings, and other specialties of silver. The first mention of this original all-metal geared honey-extractor is found in the *American Bee Journal*

for 1868, page 4. The honey taken by this machine sold at 25 cts. a pound; and even at that figure he could not supply the demand, and had calls for more. Later on, his crops were so large that he talked about building cisterns of brick and mortar to hold his honey; for several times he had more honey than all the wash-boilers, pails, and cans that he could borrow of the neighbors would hold; and all that honey was taken with that old original machine built in 1867. It embodied all the principles of the honey-extractor of to-day except that the pockets holding the combs were not reversible. The machine built by Captain Sanders, illustrated and described in this issue, page 720, was very much like it, but in principle only.

Well does the writer remember helping to extract in those early days. It was our job to keep robbers out of the honey-house by batting them down as they came in at the doorway; for every member of the family was put at work. Later, as we got to be older, we helped turn the crank. That was more fun than batting bees.

What an amount of honey we could get now if we only had the basswoods we had in those days! Fifty colonies of bees, and unlimited basswoods in the woods! for at that time no one considered that kind of lumber of any value, and every tree was standing. Our locality was not overstocked, and no wonder A. I. Root was able to get honey by the wash-boilerful, and no wonder that he was enthusiastic. As stated, this honey brought 25 cents a pound. As the scales showed that some of his hives were actually bringing over a dollar a day, it is not surprising that he should think of giving up his business up town. From some of his best colonies he took off \$50 worth of honey,* or an average of \$32.00 per colony from his 48. This exceeded even the tales in the Arabian Nights, and A. I. Root was wild with delight. His friends and neighbors when he first took up with bees had been saying that he was foolish to neglect his business and fool with bees, for they said "bees don't pay any more." But when he proved that they did, inquiries began to come in from far and wide, for he wrote up his successes and failures in the old *American Bee Journal* in the late '60's and early '70's. So numerous were the inquiries that he was compelled to get out a bee-journal, a bee-book, and sell supplies. A. I. Root's exploits in taking extracted honey gave a great boost to bee culture in the United States, second only to the invention of the movable frame by Langstroth.

* See *American Bee Journal*, page 64, for 1868.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

By way of emphasizing what is said about bees working on same kind of flowers, p. 611, it may be added that some varieties of fruit-trees are sterile to their own pollen, and, unless insects carry pollen to them from other varieties, they will remain barren.

CONDITIONS named by J. L. Byer, p. 617, are much the same as they have been here, but results opposite. Wet weather caused the loss of field bees with him; but here it seems merely to have kept them at home, saving their strength and lengthening their lives; and colonies never have been stronger.

MR. EDITOR, you have struck the nail on the head exactly when you say, p. 613, that the trouble about getting rid of the saloon has been "that the great majority of the voters would not desert their old party." As you say, a big movement is on, and whenever Christian men decide to put principle before old-party ties, and get together in one party, the speed of that movement will be quadrupled. [Exactly. But if the great majority *do not* desert their parties we are compelled in the mean time to do the best we can with the kind of voters we have.—Ed.]

P. C. CHADWICK, p. 571, reports a queen filling five combs with eggs in five days, and says, "That is performance enough for me." Not for me, P. C. I have a queen in No. 81, perhaps the best layer I have; hive overflowing with yellow bees; but she's marked for decapitation because her bees don't reliver the goods. The measure of a queen's value is not the number of eggs she lays, but the pounds of honey her workers store. [More than once we have had instances in our locality showing that the extra-yellow bees are not the ones that gather the honey. Our neighbor, Mr. Vernon Burt, said to us a couple of years ago that he had some bees that were golden almost to the tip, "but," said he, "while they are beautiful to look at, they are absolutely worthless for honey-gathering, and I am going to pinch the queen's head."—Ed.]

A SISTER beekeeper wants to know about placing hives in pairs. Advantages: Doubling the number on the same ground. The bees know right from left, and bees from the right-hand hive never enter the left-hand hive. If they go wrong it will be to enter the right-hand hive of the next pair. If two rows are placed back to back there is still

greater economy of ground room. When working at a hive it is a convenience to have the top of the adjoining hive as a platform. Disadvantage: Once in a great while some of the bees of a returning swarm will enter the wrong hive. [We have been working the scheme of putting hives in pairs at our outyards. We liked it so well that we shall continue to use it. There is one disadvantage you have not mentioned; and that is, in the spring the colony in the pair that is the stronger has a tendency to draw from the weaker. During the playspells of the young bees, the stronger colony, making a bigger show, will draw the young bees away to some extent. However, this slight disadvantage is not great enough to overbalance the advantage of being able to unite in the fall, putting the weak one with the stronger, and taking away its hive entirely.—Ed.]

THAT article by Chalon Fowls, p. 574, sets one to thinking. But isn't ye editor a bit sweeping when he speaks of a swarm according to nature having "nothing but old bees"? A bee would hardly be called "old" until it becomes a field bee. But in a natural swarm aren't there bees from the oldest down to those just able to fly? and don't you sometimes find on the ground bees too young to fly that have tried to go with the swarm? Yet a beginner might understand from what is said that only field bees are in a swarm. However, in a shaken swarm baby bees are brushed off that would never go with a swarm, and that might make a subtle difference. [You have taken our language too literally. What we really meant and perhaps ought to have said was flying bees in distinction from those that are nurse bees or those that could not fly. This does not mean that nurse bees cannot fly. Yes, it is true there is no invariable rule in regard to swarms. A swarm may and possibly does carry away three-fourths of all the bees—possibly nearly all that can fly. Some of the bees are much older than others, as a matter of course. The point we tried to make was that the old shake methods of swarm control were defective in that they took bees of all ages.

But you entirely skip over the important thing we want to know—what is your opinion of the Fowls plan of swarm control? Is it as good as or better than some other plan? It is more important to know what you think about that than what constitutes "old bees."—Ed.]

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

THE CREED OF THE WORKER BEE.
I believe in true work and the spirit of service—

Not in a visionless grinding at tasks;
But the mood that springs forth all athrill
with the morning
To find in its work all the rapture it
asks.

I believe in each giving himself for the many

Not in a sad or a spiritless way.

But fully and freely, a gift worth the giving,
As flowers give fragrance and dawning gives
day.

I believe in contentment, devotion, and courage;

Eagerness, loyalty, gladness, and song;

And in something all-wise and all-wonderful round
us—

'Tis God I believe in! To Him I belong!

We could scarcely keep up with our peaches and plums this year, and for some time the ground under the trees had considerable over-ripe fruit lying around, or that which broke when it fell, and the bees certainly did help take care of it.

An Alabama correspondent writes enthusiastically of his success with the shallow supers, including his use of them to form a divisible brood-nest, according to Mr. Scholl's method, recommending it as well adapted to women beekeepers.

We set out a few young grapevines this spring, and are not at all pleased with the way they have (or have not) grown. Still less are we pleased with the construction of our so-called arbor. So the arbor is to come down, and most of the vines are to come up. Then we shall start all over with the plan of having each vine on a single trellis by the south side of a hive. In this way we shall have shade for our bees that will not only supply us with grapes, but, according to the editor, page 611, Aug. 1, will also provide a protection from the too persistent attentions of the militant members of our apiary.

Wasn't it attractive—that honey-plant number? The pictures were beautiful, and the information was of the tempting kind that "tastes like more." When a study is both as delightful and profitable as the study of honey-plants for a beekeeper, why should we be slow about going into it more exhaustively? A knowledge of the succes-

sion of bloom becomes a guiding factor in the management of an apiary, especially in seasons when the crop is not generous and the beeman may be tempted to extract pretty close; for then he surely should know whether there is enough bloom between clover and aster, for instance, for his bees to be self-supporting, or whether, having taken most of their supplies at a time when there are few nectar-bearing blossoms, he must feed.

Won't Mr. J. H. Todd, or some other advocate of the Simmins method of introduction, explain the advantage of the darkness? This is exactly the method I have seen Mr. J. M. Buchanan, of Franklin, Tenn., use, except that, after his queen had been quite alone without food for about half an hour, she was quietly run down between the frames in *broad daylight*, the whole operation being performed at the hour that happened to suit Mr. Buchanan's convenience. It seems as though having to do the work at night might be quite a drawback in an outyard, which was where we saw Mr. Buchanan operating. He was well on his way to Franklin by noon. We ourselves have never tried it, having used cages successfully and the smoke method disastrously. But we don't blame the method. It was probably clumsy work.

It doesn't appeal to me to let the queen have the run of the hive, and from neither my limited experience nor my more extended reading can I figure out any objection to keeping her more or less confined, according to the method in general practice. To find brood scattered around in the frames removed for extraction, as Mr. Poppleton admits he often does (page 147, Feb. 15), doesn't appeal either. We were very enthusiastic over an apiary we visited in 1913, with colonies tiered several hives high, but were surprised to see no evidence of queen-excluders. Replying to our questions, the owner assured us the queen would not go above the second story to lay, but later his wife said they had had a dreadful time extracting, with brood scattered all through the extracting-frames. It seems unnecessary, when the queen can be so easily confined. I wonder just what objection Mr. Poppleton has to the use of the queen-excluder for honey production, when he says he would use it for queen-rearing (page 577, July 15).

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

The field meet held at San Bernardino recently is said to have been a big success. I regret that I was not able to attend so important a meeting so close at hand, but it was impossible for me to get a leave of absence.

I recently enjoyed a few hours' visit with my friend J. D. Bixby, of Covina. Mr. Bixby was just shipping the last of his honey to Los Angeles, where he finds a ready market for comb honey when extracted is a drag. Comb honey is all right I guess, but then—well, I kinder hate to tackle it—lots of work.

The editor tells us, page 609, Aug. 1, "how to get a cheap automobile truck for the beeyard work," which doubtless is correct; but what we need in California just now is a racing auto to run down a honey-crover. Beekeepers are a little too much discouraged at present to be figuring very heavily on automobiles.

I read in the morning paper of August 1 of a beekeeper in Florida being arrested as a spy. A German by birth, and only a short time in this country, he was, as the story goes, making drawings of important places from a military standpoint along the southern coast, and was hiding his identity by posing as a beekeeper, which goes to show that you can't always tell what these beekeepers have up their sleeves.

I use only five-frame nuclei hives for mating colonies—two to four frames in each hive. After the season is well advanced I stock them with five combs; and by spring I have a splendid start for an increase in working colonies if a good season is in prospect. The most satisfactory way to build the nucleus up to a strong colony is to set another nucleus body filled with combs over a little colony, allowing the queen access to both sections. A full colony will be the result at no distant time. A five-frame colony will build up far more rapidly on ten combs so arranged than if the combs were set into a ten-frame hive-body and the other five combs placed by their side.

There is a pretty well-discouraged bunch of beekeepers in this part of the world just now. The crop and price, none too large,

with the usual expense of supplies, makes the situation very discouraging. The price that is being offered by buyers compared with quotations to retail grocers by wholesale grocers is too wide apart to look good to the beemen. The situation resembles a transaction I have just read about in the East. A peach-grower in Arkansas shipped 41 bushel baskets of peaches to a commission house in Kansas City. He received \$2.35 for his 41 bushels of fruit. In one basket a note was placed addressed to the final purchaser, with the request that the shipper be notified what the consumer paid for the basket of fruit. A letter from the purchaser, living in Kansas City, Kansas, said she paid \$1.15 for the basket, but they had been selling for \$1.25 until that time. The shipper received less than six cents per basket, while the consumer paid twenty times that amount. Doesn't look just right, does it? Just such work as this threatens the whole business fabric of the nation.

Southern California is very much in need of a beekeepers' organization for the southern half of the state—not a state organization, but a southern California organization, something on the line of the one maintained by the northern part of the state. Indeed, I am very much in doubt if a state association is practical in this state. The elements are widely separated, and the getting-together in a working unit is very expensive, and, as a whole, is not profitable, if we are to judge by the results of the past. There has been a state organization for the past twenty-five years, yet we find ourselves groping in the darkness as to the marketing situation at this very hour. The only source we have from which to judge the market is what we are told by the buyers; and as a business policy we cannot expect them to encourage prices until they are loaded up. Then, too, they well know that, the lower the figure at which they can turn honey at a profit, the more they can turn and the greater the net profit. The condition of the beekeepers is so well known that we may be handled with impunity. We should at least get together in one central meeting in the southern part of the state. There are many of us who thoroughly enjoy the annual meeting in Los Angeles, and who will miss the opportunity to meet there the coming winter to talk over and discuss matters affecting our business.

NOTES FROM CANADA

J. L. Byer, Markham, Ontario

The white-honey harvest is over in Ontario—at least in the great majority of places. In some localities in the north, where willow-herb grows, this may give a surplus for a week or ten days yet, should weather dry up a bit; but this plant bloomed earlier than usual this year. Basswood did quite well in most places, and here in York County it gave the best spurt we have had from that source for some years. As a result the province has a fair crop of honey, and at our home yards the results are much better than anticipated when writing my July 1st notes. At the north yard we have a good crop of nice quality. With fair weather from now on, a buckwheat crop would round out things nicely, and in addition put the bees in good shape for winter.

To-day is Aug. 9—normally harvest time for the farmers, and a time when we expect the strong smell of buckwheat in localities where this plant is grown. As a rule at this season the query is whether we are apt to have sufficient moisture to make the buckwheat secrete nectar, and even the farmers often wish for rain to help the crops not already mature. But what a difference this year! Rain, rain, every day, and regular downpours at that. Wheat that is cut is growing in the sheaf, and other grain crops are level with the ground, a tangled twisted mass.

Of course nothing is doing with the beekeepers either; but our loss is so insignificant compared to the farmers' that we hesitate to complain. Rivers and creeks are out of their banks as in spring flood, and low fields are under water in many places. In twenty-four hours we had one rainfall of nearly four inches, while on several other occasions within a week an inch or more was recorded. Of course the real bright spot in all this wet time is the fact that there will be an abundance of clover next season. One year with another the rule holds good, that a real wet season is always followed by a good clover year.

In moving bees long distances, as in the case mentioned on page 522 in regard to those bees in Texas, it is hardly to be avoided in having some colonies run short of stores. But when colonies have so nearly starved as to have only a few cells of

honey, as a note of warning to beginners who may think that such a condition is not detrimental to a colony so long as it is not actually allowed to perish, I might say that, when reduced to so low an amount of stores, the brood will have suffered a lot before that. Before a colony actually starves, the bees will suck up the juices of unsealed larvæ; and from observation a few times when they had not quite reached that last stage I feel sure much of the younger brood is allowed to perish by not having food given it.

The quarantine on shipments of bees from one state to another, providing that all such shipments must have proper certificates of health before being allowed to enter a given territory, as mentioned in the case of Nevada, page 608, Aug. 1, is a wise provision, and is bound to be copied by other states and provinces in the near future. It not only protects the beekeepers, but the man importing or shipping the bees out of a country as well. Just at present I have received some redhot criticisms of a well-known beekeeper in Ontario, who, it is alleged, imported bees from one of the states, and at the same time imported European foul brood into a territory supposed to be free from this pest. I am not attempting to judge the case in any way, as I am not sufficiently in possession of the facts of the transaction to make much comment; but the fact is indisputable that, had this shipment had an inspector's certificate giving a clean bill of health, there would not be half the chance for harsh criticism. Of course it would be quite in order for the Province to quarantine any shipments for a given period, even if the bees had been inspected before shipment, especially if the load came from a locality known to have brood diseases.

Mention is made on page 611, Aug. 1, that environment and other factors have much to do in determining how bees are apt to be tempered when working with them. It certainly has, as I have had an illustration this year that proved it abundantly. At one place we had for the last few years about forty colonies that had a record for being very cross—in fact, we often thought they were really devilish. These bees stood in an open field, and when working with them they would often follow us for twenty

Continued on next page.

BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado.

HONEY-CROP CONDITIONS.

Colorado has had abundant rains this season—in fact, too much at times, and there has been too much cold and cloudy weather with the rain. We have three inches above normal precipitation this year, and a deficiency in temperature of nearly three hundred degrees. This condition has been quite general throughout the Rocky Mountain region. If we could have had higher temperatures with the same amount of rain it would have been almost ideal. The short snowfall in the mountains has been fully made up by the rains, so there has been no shortage of irrigation water to speak of.

Sweet clover is in excellent shape, and is yielding well at this date, Aug. 11; but we have had such a late season that one case of comb honey around is all we can hope for. That much will not be secured unless the honey-flow lasts well toward September. The average comb-honey crop will be less than one case for the state. In the Arkansas Valley bees are doing fairly well from Lamar to the state line. West of Lamar, as far as Rocky Ford, conditions are poor—a thirty-pound average of extracted honey being expected by one producer at Las Animas.

In the Ordway district, conditions are not reported favorable; and while bees were doing well in Fremont and Custer counties early in August, no large crops will be secured, and no shipping honey will be harvested.

Northern Colorado is blessed with abundant sweet clover, and about a one-case crop of comb honey will be secured.

Montezuma and La Plata counties in southwestern Colorado had late freezing weather this year, and the alfalfa was frozen and blighted worse than anywhere in Colorado. Sweet clover was just coming in bloom the latter part of July, but bees were doing well; and with the general late flow in September a fair crop may be secured.

Delta County has not materialized the crop that indications pointed to earlier in the season. Spraying trouble is again reported from Cedaredge, Garfield County. Conditions are very poor, and little honey is expected. The shipping crop in Colorado this year will be less than last unless we have very good honey weather from now on.

Idaho will produce some honey; but the

season in the Twin Falls country closed (or practically closed) in July.

I have six hundred colonies here in Boulder County, and have taken off only about twenty cases of comb honey. Prices have started out well, but will drop soon. Some few cases were sold at \$4.00; but most that have been sold have gone at \$3.50. A great many tourists are in Colorado this summer, and they are buying honey well. Comb honey is now retailing at 20 cts.

There has been but little swarming in eastern Colorado; and what there has been occurred mostly in August. If large prime swarms in August indicate a late honey-flow we should have it this year.

On page 622, Aug. 1, the flowers growing on the brook bank shown in the illustration are not lupins, but are the loco weed. Bees work more upon the white-blooming loco than upon the purplish blossoms. This mistake was made in writing the description of each flower upon the back of the prints. The lupin is a larger plant, with plumelike blossom stems of bluish-white flowers. I have a photograph of the lupin that I will show later.

Continued from preceding page.

rods or more when leaving the yard. One day a couple of friends came with an auto and stopped about four hundred feet from the yard. They beckoned for me to come to them; and when I came there was company with me. I can still see the driver hastily cranking the machine and going up a three-foot embankment to get to the top of the highway. Doubtless when this meets his eye he will remember the occasion also. However, this spring it became necessary to move this yard, and half were brought to the home yard, the rest being taken to an outyard. In both cases the bees are among trees and surrounded more or less by evergreens. My intention was to requenee the whole lot in fruit-bloom as I dreaded consequences of such bees near the working land of the farmers on whose places they are. But weather was bad and work pressing, and the requeneeing was not done. But the sequel of this roundabout narrative is yet to come. These bees have given no trouble in their new locations. Not a single member of the two families where the yards are located has been stung once, so far as I have learned.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

SOLAR WAX-EXTRACTORS.

"Doolittle, I came over to have a talk about solar wax-extractors."

"Very good, Jones. The solar-wax extractor is something every man keeping bees should have, even though he has as few as five colonies."

"But I am told that it is comparatively worthless for melting up old combs."

"The man who has old combs by the hundred to melt up could doubtless make it pay to employ the water or steam process; but for the ordinary collection from an apiary of from fifty to one hundred colonies, the solar wax-extractor will take care of all the accumulation during each year. From such apiaries no great number of old combs can be profitably spared to render into wax."

"But I do not think I get fifty per cent of the wax from old combs."

"Do you do more than put in the old combs and allow the sun to melt them?"

"No. What more can any one do?"

"As soon as the sun has heated these old combs so that the wax will run out from those at the bottom of the pile, take a wooden paddle and press the refuse against the side of the comb-pan where the rays of the sun strike the most squarely. You will see the wax run as you never saw it before if you have never done this."

"What shape is your paddle?"

"The paddle itself should be about six inches square, with a handle two inches wide. I made mine out of half-inch stuff, rounding the side used for pressing out the wax so that it somewhat conformed to the concave side of the comb-pan. With such a paddle, used with a rocking motion, three or four times an hour or so apart as you are passing the extractor, 95 to 98 per cent of the wax any comb contains can be gotten out unless the comb contains so much dry pollen that it absorbs the wax as it is melted. The only way to get wax from combs largely filled with pollen in quantities that will pay is by the water process."

"But don't the wax and dirt all mix together when coming from the solar wax-extractor?"

"That depends somewhat on how the extractor is built. If so small that it allows the wax, as it drips from the comb-pan in your extractor, to cool and harden as it drips, more or less dirt and dregs will come off and be mixed all through the wax, and

melting over for purifying in such an extractor is only doing over again the same process with the same results."

"How can the purifying be done then?"

"By making the extractor large enough so that it will allow the dish which receives the melted wax from the comb-pan to be in the sun under the glass, which keeps it in a melted condition for hours. Wax is purified by allowing it to remain for several hours at a temperature between its melting and boiling points, thus giving a chance for all impurities to settle to the bottom. This is exactly what can be done in the sun extractor just as easily as not to do it; and by using this extractor in any other way deprives it of half the benefit to be obtained in using it."

"But will all the dirt and dregs settle to the bottom where wax is kept melted for half a day?"

"To overcome all this dregs and dirt matter I punch two holes near the outlet of the comb-pan on either side, and, by means of a wire suitably bent, hang a small strainer made of cheese-cloth or some other suitable fabric so that the hot wax is strained as it passes from the comb-pan to the dish receiving it below. As both the strainer and the receiving-dish are in the sun all the while, the wax is so thin that a fabric can be used that will take out all but the very finest of the dirt."

"How do you keep the dregs from flowing down with the wax from the comb-pan into the strainer? The incline of the comb-pan would carry all along together."

"About two inches above the outlet of the comb-pan two other holes are made, one on either side of the center, into which go two wires to which is soldered a piece of quarter-inch-mesh wire cloth. This wire cloth is fitted at the bottom to conform to the concave of the pan. This arrests in its flow toward the strainer all but the wax and the finest of the dirt."

"What is used for a receiving-dish?"

"After doing some figuring I got our tinsmith to make some oblong square tins which hold two pounds of wax, when the melted article came within a quarter of an inch of the top; and when the proper amount was in, the cover was shut over the glass till the wax was cold, when it would come out in a brick form suitable for a fancy market. In this way it could be packed in a proper-sized box and shipped in perfect condition to any market."

GENERAL CORRESPONDENCE

EUROPEAN AND AMERICAN FOUL BROOD

BY R. F. HOLTERMANN

It has at last become my experience to know what it is to have European foul brood among my bees. Could I do so it would not be especially edifying to tell any one how I got it; but for some years I have been looking for its appearance, and, according to advice, I have aimed at having only Italian bees. Just now I am not prepared to say that the disease attacks black colonies more readily or more severely than Italians; yet I have no doubt, from the abundance of disinterested testimony, that such is the case, and I am substituting Italian queens for blacks in such cases.

ITS SPREAD.

Some one has written to me saying that I can be thankful that it is not American foul brood; but at present I can by no means agree with that view. Contrary to the statement of those who have gone by hearsay, I have never had more than seven colonies out of a hundred in any apiary with American foul brood, and I think I am correct in saying that only once in over thirty years of beekeeping have I had that much.

With American foul brood I have sought to isolate the occasional cases of disease; and in doing what I could I have burned and buried not only brood-chamber combs, but surplus combs and honey, and charred the inside of the hive and burned 12-oz. duck quilts. This burning was done for fear of any little slip in handling or rendering that which might have brought them in contact with the disease. In this way I have been able to stamp out the disease, and, to illustrate, have not seen a cell of American foul brood in any apiary of ours for some time. I feel confident that, with care, I can get rid of American foul brood by isolation and by the destruction of any thing that I know has the germ about it, bearing in mind the prevention of robbing or of feeding any honey back to the bees, even if I think there is no disease in the apiary. Feeding back honey has resulted in the extensive spread of the disease in the apiaries of some very well-known beekeepers.

When it comes to European foul brood, the possibility of stamping the disease out when once it has been introduced appears to be a question which can be answered by

many only as being doubtful. Probably some prefer European foul brood because the bees can clean it from the cells or because some advise not shaking the combs, and in this way a saving appears to be made.

TREATMENT.

When the first cases of the disease were found I was not quite sure what it was. Owing to a pressure of work the actual condition of things did not take proper hold of me. I wrote the inspector, who was absent, and left matters for about a week or ten days. Then I decided, let it be what it might, I would treat the colony as if it had American foul brood, feeling that I had lost valuable time over it. I shook every colony having any trace of it, and put the bees on starters and then on full sheets of foundation. But, as many of us know, this takes the courage out of bees, or wears out their powers to secrete wax.

I decided to take out all combs with more than a few cells of diseased brood, stack this brood upon a colony with the disease, let the healthy brood hatch, and allow the bees to clean out the disease. Thinking this matter over during the night, I decided I had made a mistake. The disease is transmitted in some way different from American foul brood, and one great distinguishing characteristic is that in American foul brood the diseased brood is untouched by the bees. In the other case it is cleaned out. In the process of dragging out the diseased brood, the bees get the germs on other parts of the comb, and their own bodies become germ-carriers, even to the field, garden, and wood, and leave them on blossoms, even miles from the apiary. Thence they may be carried miles in another direction by visits from other bees, and be brought in contact with brood in other hives.

In fact, in my estimation a colony of bees quite distant from a diseased colony getting the disease shows that it is not likely to have obtained it from stray bees. For the above reason I try to allow no cells to be cleaned out by the bees. Where a cell or two or even more are found in a hive we have cut around it, keeping away from the disease, and can put this cut-out comb into a tin can and afterward burned it.

Where the disease is in an apiary, and

bees have come in contact with the germ, there would be very great danger of the spread of disease. Such a case would be that of robbing from a common source, such as from combs after extracting, and from exposed honey.

For years I have said that when European foul brood struck our bees I would throw up the sponge, leave out, leaving the outfit behind me. I may do this yet, I sometimes think. However, since adopting the above radical methods we have found, I think, only two cases we had not seen before. At the same time, we have had too much work to do to look very carefully for dead brood.

Lest any one might be anxious lest he might have the disease from queens or colonies shipped by me, let me say no one has received a queen out of any of our

apiaries this season; and with one exception the bees shipped out were from an apiary which even now has shown none of the disease. In that exceptional case the man was written to at once, and told that the disease had been found in the apiary from which the bees were supplied. It appears to me that when the disease is in a new section of country, as in this case, beekeepers should be warned, so they can be on the lookout. The statement which some have made, which came first hand from a friend last year who had been told that I had been importing the disease into Canada, is totally untrue. No inspector nor any one in my employ, nor myself, had found a cell of foul brood in anything I have imported.

Brantford, Ont.

PRUNING DISEASED CELLS FROM A COMB; IS THE PRACTICE SAFE?

BY J. F. KIGHT.

I have just had an experience which, so far as I know, has never been reported to GLEANINGS in a similar manner. In early May I bought seven colonies of Italian bees and placed them in an outyard; but before doing so I examined them carefully twice, about eight days apart, and found them to be in fair condition, and breeding up well. Knowing the presence of American foul brood in the neighborhood I took particular pains to see that they were not diseased. I examined them again on the tenth day after bringing them home, and, to my surprise, I found six of them with from one to six cells of American foul brood. As soon as nectar began coming in I placed a super of starters above them, and, with a little smoke and a little hammer, I drove them above. Then at the end of the 48 hours I placed them on full sheets of comb foundation and left them as cured. I stacked the six old diseased hives by pairs, and at the end of 21 days I shook all the bees off the diseased combs on to the starters, and in 48 hours I gave them full sheets of foundation, and felt sure I had perfected a cure.

Now comes my story. In making this last cleanup some bees with infected honey must have gone into a hive just in the rear, for I found in about twelve days three diseased cells in one frame. The queen had almost filled every comb with brood, and to destroy all of them again seemed too great a loss, so I decided to prune. With a sharp long-bladed pocket-knife I cut out

these three diseased cells, making a hole in the comb about an inch in diameter. That was over a month ago, and there is no disease in this hive, and now it is one of the best and strongest colonies. So it seems that, if the disease can be detected in its incipient stage, pruning might save it. Certainly it has done so in this case.

It will be noticed that in the first case I drove the bees, and in the second case I shook and brushed all off. The reason I prefer to drive in the first instance is that it is no trouble to cause the queen and the old bees to rush to the top hive from the smoke and hammering; then there are left enough young bees to care for the larvæ. Besides, this drive system is more sanitary and there is less danger of spreading the disease. The second shift, all bees must be saved; hence it is necessary to shake and brush.

I should be glad to know whether or not this disease has ever been cured in a similar way.

Indianapolis, Ind., July 21.

[We have had reports from those who have pruned out the diseased cells in a colony showing American foul brood. In some cases a cure was effected. But it is fair to say that we have had reports from other people who have tried this pruning business and found it unsatisfactory. It may eliminate the disease for a time; but sooner or later, especially when the stores are pretty well eaten down, the old disease

Completely equipped honey-house of B. N. Allen, Birmingham, Ala.

will reappear. In the same way, a heavy honey-flow will cover up the infected material; but when this honey is consumed, and the bees get down to the old original stores that were left, foul brood will break out again. In some cases, doubtless, the pruning cure will be complete; but you can never tell. Some day it may break out again, perhaps a year or so hence. Of course, there are objections to shaking, chief of which is the cost, the loss of brood, and the destruction of otherwise good combs. By stacking up you saved the brood but you didn't save the combs. Well,

when the disease broke out again, and the givies had been shaken, you probably did the correct thing to prune it out; but you would do well to set those "pruned" colonies in some isolated location, and watch them closely next year when the stores are pretty well eaten down.

In this connection, during the honey-flow combs should never be shaken. They should be brushed with long grass or weeds. These extemporized brushes should then be burned or buried. The combs may then be stacked up or burned. [Ed.]

THE HIGH COST OF LABOR. AND SOME OBSERVATIONS BY THE WAY

BY L. W. BENSEN

I am wondering who could afford to pay five dollars a day for a hired man to work with bees alone. I am a hired man myself, and I am satisfied with two dollars a day the year round. I have worked for several years in different states. All my employers paid what they could afford, and in every case I had a home and the work was a pleasure. They furnished me good board,

and an automobile to ride to outyards. Everything needed was handy.

If the owner is to pay five dollars a day for labor, what is he to make? If I cannot make two dollars for the man I work for, I would rather quit and give him a chance to get a better man. I have bound wheat at a dollar a day—hard work, but no harder than taking off honey. To work the year

round is easy. I sit and put in foundation. It is just as easy as to sit and read. I have put in a whole lot in one day, too, for Mr. B. F. Smith, of Cowley, Wyo. I have filled 60 supers a day, two pieces in each box, 28 boxes to the super, and I tried to put them in as well as Miss Wilson does for Dr. Miller.

No other business on earth requires a more reliable man than the bee business. A man must not only know how to do the work, but he must do it on time, and a lot of it, to earn even \$1.50 a day.

This honey-house, owned by my present employer, Mr. B. M. Allen, of Birmingham, Ala., has a concrete floor, hydrant water, stove, roll-top writing-desk. Outside are shown some of the 200 hive-stands that I am painting, ready to replace old ones. White ants are hard on wood here. I painted with roof tar. There are 250 colonies near this house.

No, I do not use the tank shown in the

illustration for extracted honey. It holds 14,000 gallons of water supplied from an artesian well.

For cutting foundation I make a miter-box, similar to what carpenters use, except that I make it the same width as the foundation used and six inches longer. It is high enough to hold twenty-five sheets of foundation—a block held a little at the end to butt the foundation against, another to push it along. The same saw-cut is used to cut narrow and wide starters. I use a case-knife with a wavy edge which is sharpened all along on one side, so that the bevel pushes the foundation away.

Not so much of the melted wax gets on the end to stick to the cut-off sheet. Then, too, I wipe all the wax off the knife after every cut and keep the caseknife blade on the hot plate of the foundation-machine. It is as easy to cut foundation as to eat buck-wheat cakes and honey.

Birmingham, Ala.

THE POLLEN-YIELDING WATTLES

BY T. RAYMENT

The wattles are undoubtedly the national flowers of Australia. Like the gum-trees* they are spread over the entire continent in varying forms, some of which are very beautiful indeed. The illustration depicts the bright-yellow pollinia very clearly. When fully opened the flowers have a unique fluffiness extremely difficult to delineate. A close scrutiny of the blossom gives one the impression of floral pompoms composed of delicate stamens radiating from a common center. The specimen shown is a native of New South Wales, generally known as "Cootamundra" wattle (*Acacia Baileyana*). This variety is greatly favored for garden planting on account of its rapid growth and great beauty. The foliage is very feathery and of a rare shade of green, somewhat like that of the carnation.

While Australia has a vast number of

good (eucalypt) pollen-plants, none are comparable with the wattles. In GLEANINGS, June 15, J. E. Crane desires an analysis of pollen. We are better off than that, for we have had many samples of pollen analyzed, and the wattles are away ahead of anything in Australia for nitrogenous protein content. It is doubtful whether any pollen in the world is richer in the essential

Floral pompoms, delicate stamens radiating from a common center.

* The vernacular name for the various species of eucalypti.

elements so necessary for the maintenance of bee life. Pollen grains in the bees' stomachs are in a growing condition—*c. g.* live food. No meal substitute which is inert—can ever adequately take the place of the natural supply. Better plant a variety of pollen-bearing plants, and for this purpose there are none better than the Australian acacias.

The wattles should thrive in the United States, and the profusion of bloom—which completely eclipses the foliage—should surely delight the apiarist and his bees. For potato land the silver wattle (*Acacia dealbata*) is eminently suitable. Sandy loam country for the black or tan wattle (*Acacia decurrens*) and rising stony land for the golden wattles.† A characteristic feature of the Australian "bush" or forest is the great number of wattle seedlings that come up after the terrific roasting of a brush fire. This is due to the heat cracking the hard seed covering and permitting moisture to reach the vital germ. When handling wattle seeds it is advisable to remember this, and to pour boiling water on them the night before planting; also do not give any manure or fertilizer.

Some of the Australian forests are composed of one variety of eucalypt only—*c. g.*, yellowbox (*Eucalyptus melliodora*). While this tree yields splendid crops of honey—up to 300 lbs. per colony—it furnishes little or no pollen, consequently strong colonies dwindle down to mere nuclei. It will be seen from this that the question of a pollen substitute is a vital one to Australian apiarists.

† *Acacia pueraria*.

About pollen substitutes, we have had the best success with the white of an egg—almost pure albumen—beaten up with powdered sugar to a candylike consistency. The bees breed up very strongly on this compound.

In all the discussions we have heard or read on this subject, none appear to dwell on the inert character of all meal, such as peameal, rye flour, etc.—substitutes. Illustration: A man buys a paddock and sends a sample of soil to the agricultural chemists for analysis. This report states that it possesses all the constituents necessary for the production of a maize crop, and yet maize may refuse to grow in that paddock. The elements are there, but inert—that is, they are not in a form suitable for plant assimilation.

As the readers are probably aware, the bark of the wattles is rich in tannin, and is valued on that account for making leather. Black wattles are ready to strip when about seven years old; and the bark is worth about \$35 per ton. South Africa has planted them extensively, and has built up an export trade in tanbark. The Cootamundra wattle begins to bloom when about three years old; and to see an Australian river with a golden border perhaps a couple of chains wide is a sight never to be forgotten. During spring time special trains run from Melbourne, the metropolis, to enable wattle-lovers to appreciate the golden glory.

Braigolong, Victoria, Aus.

Editor's Note.—This is the concluding article of a series of three by Mr. Rayment on certain important pollen and nectar yielding plants of Australia.

IN THE WEST VIRGINIA HILLS

BY JAMES I. LUTES

When I was a small boy my father kept bees on the farm in the old-style box hives. Some were in hollow logs sawed about two feet long and chiseled out and smoothed up in the best possible way. A few colonies were hived in nail-kegs. A square box or small store-box answered for a super, with a small hole bored in one end for the bees to escape.

When he thought the box was full of honey he would just take the cob or old rag from the hole in the end of the box. He would pound on the sides and top, and if it sounded as if it were full of honey he would remove it. This was along in the '60's and '70's when meager attention was given to beekeeping.

Whenever a swarm issued he would gather up old buckets, dishpans, and sleighbells, and rush out at breakneck speed to get them to settle on some nearby limb. At the present we hoot at the idea of making such a fuss and worry. We just let them alone—by far the better way.

I have been a merchant for the past thirty years, and a beekeeper for five or six. I have had the bees merely for pleasure and recreation. I love Nature, and like to work and be with the bees. They seem to bring me rest, and cause me to forget the cares and worries of business.

About six years ago I purchased some bees from a neighbor who was getting very old, and was unable to look after them

The bees bring me relief from business worries.

any longer. The six stands were in the old Gary hives. The same winter they all died. That year there was much black honey, which I believe killed them. Possibly the honey-dew had some effect. The loss of thirty dollars discouraged me somewhat, but I decided to try my luck again.

I then procured two stands of Italian bees which I have in my apiary yet. To the present time I have increased them to fourteen.

Part of my bees are in the ten-frame

chaff hives. Since I have sold my general merchandise business, my health demanding outdoor work, I am now going to pay more attention to my bees and live out in the open. I want to get God's pure air and sunshine, and be away from the shut-up store.

I have a beautiful place for my apiary. It stands in the orchard close to a small stream where the ground is perfectly level.

Glen Easton, W. Va.

WHY QUEENS LAY IN QUEEN-CELLS

BY J. E. CRANE

On pages 489 and 490 are some original thoughts and theories by J. E. Hand, presented in an interesting way. I have neither time nor disposition to reply to them all, but will content myself in calling attention to one or two of them. In this he tells us that "broodiness in queens, as in hens, is a period of temporary exhaustion of fecundity during which the ovaries are speedily developing another batch of eggs. During this period of broodiness, which varies in duration with different queens, the mother instinct predominates, and the queen will lay eggs in queen-cells at no other time." Italics my own.

Now, if our friend Hand had said that this was true in many cases, we should doubtless have agreed with him. Or if he had said it was far more often the case than the average beekeeper suspects, he would not have been far from right. Or if he had said that he believed such to be the case we should have had little disposition to disagree with him; but when he states it as an absolute fact I beg to differ with him.

The next day after reading this article I went to an outyard where I found a colony, one of the most populous in the yard. It had a last year's queen and a large amount of brood in all stages. In fact, the bees

had carried most of the honey into the super to make room for brood in the brood-chamber. There was no evidence that I could not discover that the fecundity of the queen had been exhausted some ten days previously, as there was a large amount of eggs and unsealed larvae in the hive. It was, in fact, almost the only colony I found in the yard preparing to swarm, with perhaps the most prolific queen. Did she place eggs in the queen-cells because of the exhaustion of her supply of eggs, or was it for lack of room in which to lay her super-abundance of eggs? I thought the latter reason most in harmony with the facts.

Again if, as Mr. Hand states, the eggs are laid in queen-cells because of the exhaustion of eggs we should naturally expect to find eggs most frequently in queen-cells in large hives where the queen has a large amount of room for egg-laying. But instead we find eggs in queen-cells most often in small hives where her laying has been restricted.

We sometimes have seasons in which a large amount of brood is reared with very few eggs in queen-cells as little honey is coming in, and the bees wear out rapidly, but in other years, with less brood in the hives but honey abundant in the fields, we find almost every hive supplied with eggs in queen-cells. Can it be that queens are more broody in seasons of abundance than in years of famine?

Other reasons might be given for disagreeing with Mr. Hand along this line, but enough has been given to show that there is more than one cause for queens laying in queen-cells. I believe there are many, and temporary exhaustion of the supply of eggs is only one of them.

House apiary of W. H. H. Stewart, Emerson, Ill. Mr. Stewart writes that he considers the keeping of bees out of doors a "makeshift."

Another matter with which I take issue with my friend is sealed covers for winter use. He tells us that "sealed covers on the inner chambers under the packing preserve the heat." This, in a sense, is true; but it is not the sealed covers that preserve the heat, but the packing. We do not cover a sweaty horse in winter first with an oilcloth or rubber blanket, and then a woolen blanket to keep him warm. No! we cover him with a good woolen blanket, and if that is not enough we put another woolen blanket over the first. We do not keep ourselves warm in severe weather by placing first over our bodies an air-tight covering, and then over that woollens or other cloths to retain the heat, and then leave off our shoes and stockings for the air to circulate be-

neath our clothes to take up the insensible perspiration. No, we avoid all garments that will retain moisture, and use only those that will retain heat and allow moisture to pass through.

I agree with Mr. Hand that porous packing called an absorbent is a misnomer. It is not an absorbent. But if I were to hazard a guess I should guess that the principle of the use of winter packing has often been misunderstood. The fact that it is often spoken of as absorbent leads me to think so.

The object of packing is not to absorb moisture, but to conduct moisture away from the brood-chamber without letting the heat escape. If we were to call a cushion used for this purpose a moisture-conducting and heat-retaining cushion you have the idea exactly. If a cushion or packing fails to do this it is a failure. If we were to use

a sheet of iron or a flat stone over our brood-chamber we should have exactly the opposite result—viz., the retention of the moisture and dispersion of the heat of the hive. A properly packed hive allows very little air to escape through the packing or very little upward ventilation. I doubt if as much air escapes through the top of a well-packed brood-chamber without a sealed cover as from a brood-chamber with sealed cover and large entrance.

I began the use of packing above brood-chambers more than forty years ago by the use of a thick layer of wool over a cloth above the frames, and I am still using old cast-off woolen cloths for this purpose. I do not use them for absorbing moisture, but as a good material for retaining the heat of the hive, and allowing the moisture to escape.

Middlebury, Vt.

PICKLED PARAGRAPHS

BY BENJAMIN F. KIRK

Lots of ink is spilled in cussing and discussing the old box hive; but there's no hive that baffles the inspector like the modern hive with crossed combs and the bottom-board nailed firmly on, unless it is the old box hive with the bottom-board slipped up on the inside and nailed in from the sides. But what's the use of mentioning it, as I have been told with emphasis by good authorities that those hives were not constructed with the view of facilitating the work of the inspector? The accompanying

photographs show conditions that inspectors meet too frequently when attempting to inspect comparatively modern hives. There is no branch of rural industry that is treated with such careless indifference by the average farmer as beekeeping.

It may seem paradoxical; but experience bears out the statement that quite frequently the only man in the community who is harboring foul brood is the up-to-date beekeeper who emphatically demands that the inspector come to his community at once

and make his neighbors clean up. This is not said in a spirit of criticism, but simply to show that the business beekeeper frequently invites foul brood by buying queens, bees, and appurtenances of the apiary. He himself brings in the disease, and then innocently assumes that it has been carried in by his bees robbing his neighbors' extinct colonies.

I often wonder why more of the intelligent young beekeepers who are striving to get nice apiaries established do

Too frequently inspectors meet conditions like this.

not take to teaching school during the winter months. Teaching would give them pleasant and profitable employment for the part of the year that is not so much taken up with the work of the apiary, and would still leave them their Saturdays to look after the needs and condition of their bees. It would give them a salary as a means of support instead of having to rely on the income from the bees, and therefore hindering and retarding their progress along their chosen line. It gives the young man a prominence and an established standing in the community that is a valuable asset. Teaching broadens the mind, and is conducive to the cultivation of the finer qualities that make up a good clean character.

John W. Love's article in the May 15th GLEANINGS emphasizes a very important and much neglected principle. It is frequently said that if the farmer would keep books and count the cost and returns on the various enterprises that, taken collectively, make up the business of farming, many a farmer would in five years find that his net income had doubled because he had eliminated those things that were losing money for him. Again it is asserted, and not entirely without reason, that if the average business man would run his business in the way the average farmer runs

But what can the poor inspector do?

his, he would be in the bankruptcy court inside of two years. How many beekeepers *know* that they are making a cent per pound more out of their honey than they are investing in supplies, labor, interest on the investment, depreciation, etc.? If a business appears profitable when conducted in a slipshod manner, what might it be if a little gray matter were added?

The dearth of honey last summer, followed by the filling of the brood-chambers with aster honey last fall, was the first indication of inevitable trouble. The large number of dysentery-spotted frames and weak and dead colonies loudly testify to the effect of too much aster. It seems to be pretty well established that aster is detrimental in most localities, and a practical means of circumventing it is now in order. Suppose that some of the would-be hive-inventors turn their guns in that direction.

A FIELD OF BUCKWHEAT IN EASTERN MASSACHUSETTS

BY MRS. SUSAN E. HOWARD

Buckwheat is not planted to any extent in eastern Massachusetts. Indeed, it is the exception to see a field of it. My object in planting was for a cover or fertilizing crop to be plowed under.

The second sowing after the first had been plowed in was allowed to mature, and straw was used to cover strawberry-beds. It made an ideal winter protection with the addition of meadow grass. This second sowing was made forty days before the date of the annual field meeting of the

Massachusetts Society of Beekeepers which was held at my apiary. As it takes about thirty-five days from sowing to blossom, it was at its best, and was a beautiful sight as it was in full bloom.

The bees work it well from early morning until about 10 A. M., and then again from 4 to 8 P. M. The morning flow was most pronounced, and the field was alive with bees.

Whether there is a cessation of nectar from the buckwheat during the rest of the

Honey for the bees, seed for harvest, fertilizer for the ground —buckwheat should be planted more extensively.

day, I am unable to state. Perhaps there was a flow more alluring during the intervening hours.

As I raise bees rather than honey, it served an admirable purpose in that it stimulated brood-rearing during a season when nectar was scarce. To recapitulate, it served to keep the land mellow, kept down weed growth, and conserved the moisture, also supplying humus if plowed in while green.

The blossom afforded honey to bees and afterward seed for harvest. The stalks were used as a winter cover for strawberry-beds, and, in the following spring, well disked and plowed into the ground.

I have had but one year's experience with buckwheat, and so I am unable to state its dependibility as to nectar secretion, but am firmly convinced it should be planted more extensively.

Stoneham, Mass.

MODIFIED SMOKE INTRODUCTION

BY L. R. DOCKERY

Inasmuch as there has not yet been a method of queen introduction given that is fool proof I will explain the method I have been using the past two years. In that time I have introduced about two hundred queens and have lost only one, and that loss was due to negligence. This method, in addition to being proof against the neglect just mentioned, is so practical and sure that it will commend itself to the specialist. It is practicable under all conditions. I have introduced queens to colonies with fertile

workers, those with cells almost ready to hatch, and those just made queenless, with equal success.

The queen should be kept from food and other bees for about thirty minutes. She should never be taken in the hands, but caught or caged by placing the cage over her while on the comb. If she is received through the mails, change her to another cage without any bees or food. To introduce her, give a little smoke at the entrance, then take off the cover and smoke them again. Take three combs from the brood-

nest, and shake or brush all the bees in front of the hive. As the combs are freed of bees, return them to the hive.

When this is done, place the cover on the hive. As the bees pass in at the entrance release the queen among them; and as she

passes in at the entrance give her a little smoke, and she is introduced. If the colony has been queenless some time, or if there is robbing going on, the colony should not be disturbed for forty-eight hours.

Winton, Cal.

A HIVELESS COLONY

BY ANDREW CARMAN

The accompanying photograph is one of a freak scrub of wild honey. I have found and cut 163 bee-trees, having hunted bees ever since I was old enough, and I have never before found a comb similar to the one here shown.

Last fall I followed bees to a large sound hemlock - tree about eighty feet high and two feet in diameter at the stump. The tree was growing at the top of the gorge below the Devasego Falls in the Schoharie Creek in Schoharie County, N. Y. While watching the bees trying to find the hole in the trunk where they entered, I discovered the comb shown in the photograph hanging to a limb about fifty feet from the ground. The only protection from the weather the bees enjoyed was the limbs of the hemlock above the comb and the surrounding trees which acted as a windbreak.

The tree was climbed with difficulty, the bees subdued, the limb holding the comb sawed off, and carefully lowered to the

Too careless to look further, the bees had settled on a limb.

ground by means of a light rope.

The comb, deducting for the estimated weight of the limb, weighed forty-four pounds.

Evidently the bees, having swarmed on the limb, began work immediately, not troubling themselves to look further for a more sheltered harbor inside a hollow tree.

Plattsville, N. Y.

FEEDING BEES IN LESS THAN HALF A MINUTE

BY WILLIAM BEUCUS

In the issue for Oct. 15, 1914, appeared an article, illustrating my new combination live-bottom and feeder. The spring of 1915 was very cold and rainy, and the new feeders came in very handy. They far excel anything I have tried so far, nothing to put up, nothing to put away. On any day, too cold or rainy for the bees to fly, just fill a pail with warm feed and squirt

some in at the entrances. The pans catch it so there is no waste. It is not necessary to move any pieces nor even to stoop much. One hundred colonies can be fed in an hour

in fact, 116 were fed in 45 minutes, less than half a minute to a colony. It's more fun than to go to a good show to feed the bees on a cold raw day.

How different it was a few years ago when

Just a jiffy to squirt in the feed.

the spring happened to be bad and the bees ran short of stores. Everything was pressed into service. And then, too, we even filled combs with feed and had to open hives to get them where the bees could get at them. These are the experiences which make one disgusted with beekeeping. It is simply unpreparedness, failure to look into the future and get ready for contingencies. But with foresight, with preparations for unfavorable conditions made, what was before painful is changed to positive fun. In the future, every additional colony of mine will have as a part of its equipment one of these feeders.

Here is another point to consider. Suppose I want to raise some queens, and the honey-flow at the time is lacking or intermittent. I just step out and squirt some feed in at the entrance. It takes only a minute because everything is always ready.

We are continually at war with surrounding forces—forces which are always endeavoring to overthrow the balance and bring death. In the long run, the overthrow is accomplished; but in the span of days allotted to each, success or failure results from anticipating what conditions are to come and making preparations to meet them.

The year 1914 was a complete failure in apiculture so far as surplus honey was concerned, and one of my neighbors told me that he remembered a year when not only had there been no surplus but no honey for wintering. When such a year comes, what a satisfaction it will be to know that every colony is supplied with an equipment to meet the opposing changes. Keeping up brood-rearing in the fall and feeding up for winter can be accomplished with very little labor.

After reading the editorial entitled "How to Feed Bees on the Verge of Starvation, without a Feeder, and Do it with a Minimum of Labor," GLEANINGS for July 1, I felt gratified to think that my bees are always ready for feeding. I have many times fed bees just as described by the editor, and doubtless every other professional beekeeper has also. To me it has always been a disagreeable task to open a hive in cold weather—particularly a hive containing a strong colony. The bees stick to the cover, get into the grass, and an occasional bee alights on my person, crawls under my coat, up my pants, or even under my veil. Under such circumstances I have done considerable muttering in my beard.

Cadott, Wis.

WEATHER, AND LOTS OF IT

BY A. L. BERGQUIST

It has not been all sunshine for beekeepers around here this year. April opened nice and warm; but all of May and up to the present, June 14, we have had unfavorable weather, cold and rainy. The picture shows how the hives were covered up with ice and snow at the cold spell we had May 16, 17, 18.

The clover here was badly winter-killed, so we shall have to look forward to the basswood for a crop of honey this season.

Lindstrom, Minn.

[This picture is interesting at this time in that it shows some of the extremes of

May 18 in Minnesota.

temperatures that the bees may have to withstand in the late spring. Good preparation in the fall is a good form of insurance.—Ed.]

A PRIMEVAL HONEY-EXTRACTOR

BY P. C. CHADWICK

It recently came to my notice that Riverside County, Cal., has one of the oldest extractors in the nation, and, without doubt, the oldest in the West. The matter of the origin of this machine has a history well worth a place in the annals of inventions—not that there were no other extractors in the market at the time of the manufacturing of this one, for there were a few. But the inventor, Captain Jeremiah Sanders, 87 years of age, had no knowledge of there being an all-metal extractor in existence at the time he conceived the idea of having this one made.

It was made in San Diego, in February, 1875, by a plumber, W. A. Begole, under the directions of Capt. Sanders. In the accompanying illustration may be seen something of the shape and substantial work in this machine.

I had a visit with Capt. Sanders in December, and a pleasant one indeed. Although a man of 87 years, blind, and a cripple for the past fourteen years, his mind is clear and his memory excellent. He took me back over the early days of California beekeeping, when he first came here and began working with bees. He told me of the wonderful crops secured in the early days—crops that Capt. Sanders thinks we

shall never see again. He was personally acquainted with both of the firm of Clark & Harbison. Capt. Sanders became interested in bees in 1867 in Johnson County, Mo., and moved to California in the early seventies, going to San Diego County to locate. He first worked for a man by the name of Mitchel, later taking up the work for himself. From San Diego County he came to Riverside County, where he followed the business for a number of years. Fourteen years ago he was attacked by a vicious bull and almost killed, though he recovered to such an extent that he has been able to go with difficulty on crutches.

The can is a very heavy galvanized iron. The cross-bar holding the gear and baskets is an exceptionally heavy casting. The can is in two parts. The upper part, holding the baskets and gearing, has a cone-shaped open bottom, and rests in the lower part, or honey receptacle, telescope style. That is to say, the upper division fits into the lower part tightly. The lower division has an opening for a faucet or plug to allow the removal of the honey from below. This arrangement does not show well in the picture, which was taken at near sundown, and it was impossible to get the light necessary to show all of the parts.

Capt. Sanders and his all-metal extractor which he designed in 1875.

Capt. Sanders has kindly loaned this machine to the A. I. Root Company, and it may be seen in the company's exhibit at the San Diego exposition. Beekeepers should be sure to see this machine when attending the fair, for it not only shows the inventive genius of Capt. Sanders, but also something which has a place in the early history of the beekeeping industry of the state. Many extractors of this type were made at San

Diego, and used in the early days in that section. The second machine was made for Mr. Clark of the firm of Clark & Harbison. While Capt. Sanders was not the first to make an all-metal extractor, he deserves a place among inventors, because of the initiative he has shown. Capt. Sanders prizes this machine very highly, as it is the only relic of his beekeeping days he has retained. Redlands, Cal.

EXPERIENCES WITH QUEENS AND THEIR INTRODUCTION

BY W. M. SMITH, B. A.

As much has been written touching on the introduction of queens by the smoke method it would seem useless to discuss it further. However, as this is the time of the year when such problems are perplexing the minds of beginners, and as I am situated in a novel position, living at the very western edge of the continent, and have been continually importing queens from the East, my experience in their introduction might be instructive, or at least interesting to others.

Some years ago when I started introducing new blood into my original native stock,

new problems stood in my way. Queens from the opposite side of the continent were, up to the year 1913, introduced by the cage plan. This worked with indifferent success, if they were introduced before the end of the honey-flow which ends in July with us. But when attempted later, in September or October—that is, after the honey-flow had entirely ceased—there was invariably a large loss running as high as 80 per cent.

When the smoke method was brought forward with such enthusiasm I naturally accepted it as a panacea for all my trou-

bles. In the summer of 1913 I received queens from several different breeders, and promptly undertook to introduce them, upon their arrival, by the smoke plan. The whole dozen which I had at this time were successfully introduced, and the greater majority were laying in two days. Consequently I hailed this as a cure for all past troubles. This was at a time when nectar was coming in quite freely. Had it been otherwise the results would have been different, as I learned later.

About a month later I received some queens and attempted to introduce them by the same method; but I was astonished to find that not more than ten per cent were accepted, due to the fact that nectar had ceased coming in.

Last fall I delayed ordering all my queens till late, and attempted to introduce them by the smoke method, but found them all later carried out to the front of the hive. I then tried the cage plan, but with no better success. Almost exasperated, and with a couple of dozen queens on my hands, I looked in vain for a solution. There was no nectar coming in, and brood in few of the colonies. I put the cages (wire down) over the brood-chambers of a couple of strong colonies, knowing that the temperature was about right for the health of the bees. About a day later I again decided to try introducing them by the smoke method. I removed the old queens one day; and the next morning early, while all was quiet, I ran in the new queens at the entrance after smoking. To my surprise practically all were accepted.

Fired with this success I immediately ordered a dozen more, as I had about that many colonies which I wished to requeen. These did not reach me until October. I now placed the cage with each queen over

the brood-chamber of the colony to which she was to be introduced, removing the old queen a day later, then introducing by the smoke method the following morning when all was quiet. All were accepted, and commenced laying, with the exception of one which died later. My experience has shown me that no method will work satisfactorily after queens have been in the mails for a week or longer until all odors foreign to the hive are first dispelled by that of some colony. Apparently it makes no difference whether the queen to be introduced is placed over the colony to which she is to be given (although this is the preferable way) or over any colony, so long as she acquires the odor common to the bee.

It should also be noted that the cage plan will not work here under the above conditions, no matter how long the queen is kept caged before being released, and that the smoke method is a perfect success.

One great trouble I have had with queens mailed across the continent is that there are *never enough attendants*. It must be borne in mind by the queen-breeders that the temperature is not the same throughout the whole journey, but drops low in coming over the mountains, even in the middle of summer, and for this reason queens mailed to this side of the Rockies should be mailed in double-width cages with from 20 to 30 attendants. If there are not enough bees in the cages to keep up the heat when passing through a cold atmosphere the queen will invariably be chilled, which will impair both her usefulness and longevity. Even if she does survive, and commences to lay, she may be superseded almost immediately. It goes without saying, that such queens are an unprofitable investment for the beekeeper. Such are the results here. Is it again a question of locality?

Dewdney, B. C.

HOW TO HANDLE COMBS AFTER EXTRACTING

BY E. S. MILES

One reason why beekeeping is interesting is that there is continually something new turning up. Many of the problems are easy. With a little thought and a little experimenting we come to the "know how." The problem indicated by the title is the one bothering me now. In order to help any one to avoid offering a way already tried, I shall describe those I have attempted. What works well with one person in one place, by the way, will sometimes not work out the same with another person in a different place. What one person would con-

sider a success, another would not be satisfied with.

In saying "after extracting," I mean after the last extracting for the season; for here this takes place in August unless we have a fall flow, which has not been frequent of late years.

I have done as follows:

1. Piled them up in the honey-house and let them stand until the next season.
2. Set them outdoors for the bees to clean up.
3. Set them back on the lighter colonies,

Exhibit of the A. I. Root Company, which took a grand prize at the Panama-California exposition, San Diego.

The exhibit stands at the right of the east entrance of the Varied Industries Building.

with an escape-board, minus the escape, under them, piling as many supers on a hive as would safely stand up.

None of these methods are satisfactory, for the following reasons: The first is objectionable because the daubed honey granulates, and starts granulation too soon in the next year's crop. Worse yet, if there is comb that has contained brood it is quite likely to be ruined by the wax-moth larvæ.

The second method is objectionable because my bees gather on the combs in swarms, and fight over them, killing large numbers of bees. They do not learn to go to their hives at night, but quite frequently stay in large numbers on the combs. The only way I can get the combs in is to do so at night, and then I lose lots of bees. I have tried putting the combs out a little before night, on the theory that the bees would just about get them licked up by dark. Then I could get them in before the moths got around to lay a fresh batch of eggs.

But this will not work with my bees. They start fighting, and the supers are full of bees at dark. I think that, by leaving the combs till they are completely dry, the bees would leave them at evening. However, I do not like the idea of combs exposed to the weather and moths, nor do I care to lose many bees or have so much of an uproar around the place.

The third method is the one I have used mostly, mainly because not so many bees are lost, and because in that way the honey from the combs is given to the colonies needing it. But it has the objection of requiring too much labor, especially night work, and also that it is not feasible on a large scale unless a large number of strong colonies, light of stores, are near by.

My method in this is to put an escape-board, without the escape, on each strong light colony that we have combs for, and, if the weather is not too hot, to contract the entrance considerably. In any case I make the entrance as small as the weather will permit, doing this any time before I wish to put on the combs. Of course I lay the cover on over the escape-board. Then when I wish to put on the combs I start as soon as it is too dark for the bees to fly. Laying off a cover from a hive, I go to the honey-house and take as many supers of empty combs as I can carry, and set on the hive. I proceed thus until I have as many supers on as I wish, putting as many to the hive as will stand up safely, and being careful to have all covers fit down bee-tight. I put on an 8 or 10 lb. stone, or two or three bricks, to insure the covers staying on.

By morning the bees will have the combs pretty well licked up, and will have recovered from their excitement enough to keep out robbers.

But to get the combs off is another job requiring about as much time and labor. If one has an assistant he goes with the escapes, and a smoker well lit up, and one lifts the pile of empty supers enough at one end for the other to force in several good puffs of smoke and insert an escape in the escape-board. Then after a day or two the dry combs may be taken back to the honey-house. If robbers are bad and the weather warm, this has to be done after dark also.

None of these methods protect old brood-combs from the moth-larvæ. If one uses new combs—that is, combs that never contained brood—the moth will not damage them here, according to my experience. But in different manipulations I frequently have a set of old brood-combs that it is desirable to fill and extract. Every fall finds me with several on hand. They are valuable; yet how to care for them, without too much time and labor, is a problem I have not been able to solve.

Put these back with the bees till cool weather. This would protect the comb, but

is objectionable here for this reason: We often have about enough flow after bass-wood and clover to fill a colony up in good shape for winter if they are crowded down to one set of combs as early in the fall as possible without swarming troubles. The honey so gathered is, with few exceptions, the very best of winter stores. But by giving more ready-built combs, and especially old brood-combs, the bees will continue to breed a little heavier, using up a part of what would otherwise be winter stores, and scattering the rest through the combs in such a way that no one set would contain enough for winter.

It is probable that, by leaving these colonies till late in the fall, they would move all the honey into the top story. This is not practicable with a large number of colonies to care for, as many colonies in some seasons would be found light too late for best results in feeding.

I have gone thus into detail hoping to open up a subject that I wish very much to get more light upon.

Duquap, Iowa.

THE FOLLY OF TOO RAPID AN INCREASE

BY "OBSERVER"

Did it ever make you sore because the bees were so strong in the spring at clipping time that you could hardly find the queen?

When one does not wish to unpack colonies until nearly time for the honey-flow, a pretty fair idea of inside conditions can be determined by noting the relative numbers of spring-hatched bees and "pioneers" that are going in and out at the entrance, and noting whether they are carrying in pollen or not.

I wonder how many beekeepers are observing "dandelion day." The dandelion usually yields but little surplus, but yields a wonderful tonic of nectar and pollen that makes the weaklings strong.

Some good work for the beekeepers might be done by the forestry departments of our state colleges and experiment stations by advocating the planting of nectar-producing trees for shade purposes.

The following is a true story, and worthy of consideration by all beginners. In the spring of 1913 a husband and wife, both of more than average intelligence and ability, secured a couple of stands of bees. They determined to increase as much as possible until they would have sufficient numbers to yield a considerable return. By June, 1914,

they had 38 strong nuclei. These were formed by dividing the colonies as early as possible. Those which were divided in the spring were the product of a division the previous season. The appearance of an increasing number of dead larvæ in the hives finally alarmed the enthusiasts so much that a sample comb was sent to Dr. Phillips, who pronounced it American foul brood. The tin-tube method of treatment was then used, with the result that only two were cured. This spring there are left three colonies and fifteen nuclei. By good fortune one colony is strong, and free from disease. The rest are diseased and weak. Over \$300 has thus far been spent on the venture. As Aesop says: Moral.

The division method of increase will surely increase the number of cases of foul brood if it is present in the original colony.

If in doubt, practice natural swarming, hiving the swarm on 1/4-inch starters. Don't try the tin-tube method of transferring on a weak colony. Even success in other lines of business, and great natural ability, must be supplemented by real bee experience in building up a profitable apiary. Don't hurry the business. Starting with one colony this spring, and doubling the number each season, granting that all increase lives,

A heavy jacket was built around the tank.

at the end of the ninth season the product would be 512 colonies. That ought to be fast enough increase to satisfy almost any beginner.

Use the Division of Apiculture, U. S.

Department of Agriculture, frequently, in determining the cause of death of larvæ. If your state has an inspector, use him—that's what he is for.

Madison, Ind.

MELTING AN 8500-POUND TANK OF CANDIED HONEY

BY E. F. ATWATER

As our crop last year was light we bought several lots of honey to supply our demand, and among these lots was a tank containing 8500 pounds of alfalfa and clover honey, candied in one solid, cold, stubborn mass. This honey was to have been delivered to our shop, where we have our melting and bottling plant, but was found to be so hard that it was considered unprofitable to try to dig it from the tank.

Finally, 1 x 4 x 4-ft. boards were made into a wall around the tank, about four inches from it; then, six inches away, another wall was built of the same material, and the space between the walls was filled with dirt, leaving the air space around the tank. Then canvas was laid on top of the wall and against the tank, and covered with dirt.

The honey-gate was removed and a pipe four feet long was screwed on to the end of

this pipe. Around the tank, before building the wall, half-inch pipe was bent, with openings at intervals, and a pipe extending out to receive the steam. The tank rested on pieces of inch boards, not too close together, so steam could get beneath. When all was ready a traction engine was hired, and steam was shot into the air-space around and beneath the tank.

The honey around the sides soon melted, and the chunk settled a little. Two or three men were kept busy chopping at the chunk with spades. The small pieces slid down the sides and were soon melted. The honey was allowed to accumulate, for by stirring there was no overheating.

Occasionally a few hundred pounds were drawn off, strained, and canned. In about 1½ days the entire lot was melted without injury.

Meridian, Idaho.

The bees drink on the lily pads.

A LILY-POND FOR A WATERING-PLACE

BY REV. J. N. LEWIS

A lily-pond which almost any one can make is an ideal watering-place for bees, as well as being very ornamental. The birds utilize it for a drinking-fountain and bathing-pool.

This miniature pond as shown in the picture cost for material exactly \$2.00, and the work I did myself. The only expense was for four bags of Portland cement at fifty cents each. I simply dug out an excavation the size and shape I wanted my pond, and plastered it with two coats of cement, letting the first coat dry hard before applying the second. The rim I covered with clam-shells, which can be had for the gathering in this part of the state. If shells are not to be had, small pebbles can be used. When all became dry and hard I

put in six inches of rich loam with coarse sand on top, and planted pond-lily roots, which grow and bloom from May to September year after year. The pond shown in the picture I made six years ago, and about all the attention it needs is covering in winter to protect from freezing, and supplying with water to replace evaporation. Usually the rainfall keeps it full. If not I have a well near at hand, and it is a small matter to supply all that is needed.

The lily pads make perfect floats for the bees, and they are on them by hundreds all through the summer season. It is situated about twenty feet from the apiary, and the bees have a constant supply of water near at hand.

North Westport, Mass.

THE HOME-BUILT TRACTOR

BY XENO W. PUTNAM

Every tractor, home or factory built, consists of three general groups—the power plant, or engine, the tractive element, or drive-wheels, and the transmission, which diversifies the energy of the one into the other.

The last named is made up of several sub-groups which depend for their arrangement largely upon the engine used and the man who uses it.

Generally the best engine for the home-

made tractor is the one that the builder has at hand. If it runs steadily, without overheating; if it is handily adjusted and repaired, and easily controlled, so much the better. Most of the faults of the engine work their vengeance either upon the operator or the rest of the machinery, though they may not actually disqualify it for tractor purposes. Some of them may be absorbed in the transmission, if the builder is skillful, although probably the transmission will gain nothing because of the extra duty. An automobile engine, for instance, making 1000 revolutions per minute at the crank-shaft can be reduced to about the normal speed of 25 in the drive-wheels through the transmission gearing; but part of the latter will have to turn pretty fast, and will wear out that much quicker; also an extra shaft (with its attendant loss through friction) will probably be necessary in order to bring the speed down to the required point.

power is impaired because of the weight removed from the drivers. Three-fifths of the weight is needed there, to hold the grouters (or cleats across the face of the drivers) snugly in the ground. This balancing of the parts can usually be best accomplished by placing the engine near the rear axle as in Fig. 1, the transmission in front of it, and the water-tank still further ahead, its contents in some measure regulated by the weight required on the front wheels. It is also best not to set the engine back directly over the axle, as every jar occasioned by rough and stony ground is communicated to it without any possibility of the sills absorbing part of the shock. In fastening down a tractor engine, special care is necessary.

If the crank-shaft is not exactly parallel with the rear axle, some wheel or shaft in the transmission train will have to be a trifle out of line with something else in order to correct the fault. If a part of the

Fig. 1.—Arranging the parts of a well-balanced tractor

1. Rear axle. 2. Engine. 3. Countershaft bearing. 4. Differential shaft bearing.
5. Water-tank. 6. Tractor sill.

It is better, if possible, to set the engine with the crank-shaft parallel to the drive-wheel axle, then there will be no bevel gearing interposed, and no end-thrust to contend with. Set the engine just in front of the rear axle—the closer the better. It is then within easy reach of the operator's platform, and the tractor balances well. About two-fifths of the weight of the tractor should come upon the front wheels in order to hold them firmly enough to the ground for guiding purposes. If much less than two-fifths, the tractor may work all right when running empty on the level, and the front truck lift clear of the ground, or nearly so, when traveling up hill or on a heavy pull. Of course it would then be impossible to control the tractor. But if the engine is placed too far forward the tractor will steer unnecessarily hard because of the heavy weight on the steering-wheels, and at the same time the tractive

drive is chain transmission a little leeway is possible, though it is best to have even chain-and-sprocket members all perfectly aligned. If gear-wheels entirely are used, the alignment cannot be too carefully made.

After the engine is once set it must be so securely bolted that it cannot by any possibility shift its position in relation to the axle or any of the transmission bearings. Ordinary care may not be enough, for the jar and vibration are far greater than in the case of a stationary engine. Just how the fastening is to be done depends upon the bolt-holes and the engine-bed, but it must be done thoroughly. If there is any chance to pass sub-sills across the top of the engine-sills, and then bolt these to the side sills of the tractor, it should by all means be done. Half-inch bolts are usually about right for light tractor work, and it is safest to use a washer at each end, and two nuts instead of one for

holding each bolt. *Never use nails in fastening a tractor together.* They are certain to loosen under the continuous vibration.

For a one to three or four horse-power engine, tractor wheels taken from a worn-out mowing-machine will answer nicely. They are strong enough to stand the strain, have grouters ready cast upon their face, and will give very fair tractive power. The standard mowing-machine wheels weigh between 60 and 80 pounds, are 30 inches high, and have about a four-inch face. Any junk-dealer will be glad to furnish good mower-wheels at a cent a pound, which is three times or more what he pays for them to the farmer owner.

If a heavier tractor is wanted, binder wheels are the thing. They will answer with engines up to twelve or even fifteen horse power, and of course give very much greater tractive force, both on account of their greater weight and because of their wider face. Cast binder-wheels weigh around 165 pounds each, and the standard wheel is 36 inches high with nine-inch face. Junk-dealers supply them for about the same as mower-wheels, and get them for the same of farmers. As one binder has but one drive-wheel it is necessary, when purchasing them, to see that they are alike in size.

Approximately all binder and mower wheels are bored for the same size of axle, $1\frac{1}{2}$ -inch cold-rolled steel being used. Some binder wheels are a sixteenth to an eighth inch smaller; then the shaft has to be turned or filed down to the wheel bore. If filed, the stock must be removed from all sides alike, and the shaft kept true. It is a good plan to keep the shaft revolving slowly (by hand) while filing. Cut first with a coarse file or rasp, then follow with a medium coarse mill-file, about 12-inch, using both in a diagonal sweep across the shaft and use the opposite diagonal for each of the two cuttings. Finish with a fine light file held at right angles to the shaft, and so filing square around it. This will put a smooth bright polish upon the metal, which may be further trued up with fine emery dust upon a cloth when all the surplus stock has been filed away.

If more than a ten-horse-power engine is to be used, or if that is a heavy one, it is best to measure off at each end of the shaft the length of its own wheel hub plus the cap and room for about four washers: then cut a length of $1\frac{1}{2}$ -inch water-pipe to cover just the space between the two wheel-spaces. A pipe of this size cut to 43-inch length cost the writer 52 cts. recently, but should be had for less money. Drive the rear axle

through this until the pipe is in the center as in Fig. 2. Follow with two wrought washers at each end, then slip on the binder-wheels, two more washers, and the regular mowing-machine-wheel cap with cotter-pin dropped into place, and the rear axle.

the tractive member, is completed. As the axle itself is easily obtained from an old mowing-machine, the holes are pretty certain to be already cut for the cotter-pins. Junk-dealers will furnish mower-axes of various lengths at one cent per pound or less, and $1\frac{1}{2}$ -inch shafting of this sort weighs about six pounds to the foot. Usually a five-foot shaft is long enough, but that depends upon the size of the engine.

It is assumed that the wheels, whether mower or binder, have the sprocket or gear wheel still attached to them—this, of course, being turned to the inside in slipping on the wheel. Most binders are now run by chain and sprocket, and a good many mowers by gear. Sprocket-drive binder-wheels are the best, because, when chains are used in the tractor drive, more play is allowable, and a slight departure from alignment may be taken care of by the chains. In excessively rough ground, too, there is less tendency to cramp the transmission mechanism if one of the links connecting the engine with the ground-wheels is by means of sprockets and chains.

In the next paper, working details will be given for the transmission machinery, the differential, clutch, countershaft, and reversing appliances, etc., within which the real work of the home-tractor builder makes its appearance.

Harmonsburg, Pa.

[This is the second of a series of three articles by Mr. Putnam, entitled *The Home-built Tractor*. The third will appear in an early number.—Ed.]

Combine Simmins and Caging Methods

We have all, perhaps, heard of the man who boasted that, by the use of a certain make of stove, he was saving half his fuel, and was asked by a wag why he didn't buy another stove and save it all.

After reading J. T. Todd's article on the Simmins method of queen introduction, page 581, July 15, and editorial remarks, I am constrained to ask, "Why not combine the Simmins with the time-honored caging method?"

Cage the queen the usual time in the hive to which she is to be introduced, and take her out for her thirty-minutes' fast. During this time the hive will become quiet. Then introduce by the Simmins plan.

Ashville, N. C.

O. BROMFIELD.

Heads of Grain from Different Fields

The Backlot Buzzer

BY J. H. DONAHUE

A fellow from the city came out the other day to visit the bees. Had a fly-swatter with him. They put him out on the third strike.

Excessive Swarming in Spite of Giving Room and Enlarging the Entrances; What was the Cause?

I wish to give my experience with bees this spring which is out of the usual order of things with me. My bees came through the winter strong in numbers but rather light in stores. First blossoms came on in abundance, with plenty of dandelion bloom. As I had about all the bees that I cared for I set out to keep down swarming as much as possible. I have some ten-frame hives; and as I run mostly for bulk comb honey I got full-depth supers for these and put them on early. I also gave them large entrances. Part of my eight-frame hives I treated in the same way—that is, I put on supers with full-depth frames all equipped with starters—not full sheets of foundation. But in spite of all I did, swarming began the last of May and has kept up without intermission this far in June. Now, the unusual thing is that one swarm came out, and, without settling, went into another hive containing bees of the same race. At another time a swarm came out, and, without clustering, went into a hive where I had just put a swarm that had clustered. The early swarms were large, but the late swarms have been rather small so I have been doubling them up and putting two of them in the same hive. Is there any objection to this practice? In only one case have I found any trouble, and then I found about a pint of dead bees at the entrance after two swarms had been put together. Now, as I have written before, I am a farmer backstopper, and keep bees largely for pleasure and because I like honey, and will not go to the trouble of practicing "shoot

swarming" or looking through the hives to cut out the queen-cells. What I want to know is: Aside from these methods have I not done about all that I could do to keep down swarming? I might say that we have a good crop of white clover, but the weather has been cool and very wet for the past month, so that clover, up to date, has not yielded much. The bees have simply swarmed out, leaving the hives light in stores. So far as I can determine from an examination, not a pound of surplus has as yet been stored, and almost no foundation has been drawn out. After more or less experience with bees for more than thirty years I have never before seen the like.

Mendon, Mo., June 21.

NATHAN CLAIR.

[We can hardly understand your trouble unless it was because the conditions in your locality were decidedly favorable for swarming. A light continuous flow of nectar will stimulate swarming much more than a heavy one. You say you secured no surplus, but that there was just enough honey coming in to keep the bees in a state of excitement.]

In the matter of giving extra room, you rather overdid it. You gave too much and too early. Very often bees will not enter a super with merely starters. This is a common experience in the production of comb honey; and it often happens in the case of extracted when frames with only starters are given. Your bees probably went right on building swarming-cells when the brood-nest was crowded. If you had put on shallow supers with drawn combs just at the time when the bees needed them, or given full sheets, it would have been better. Apparently you have a strain of bees that is inclined to swarm. If they have a preponderance of black blood, Carniolans, or Caucasians, they will swarm much more than pure leather-colored Italians. Usually, giving room not too fast and not too early will have the desired result, providing, also, the bees are pure Italians. But even then it is wise to look out for swarming-cells. These will usually force out swarms, no matter what the conditions are. Next season, or before that time, rather, we would advise Italianizing your stock; and just about as the bees begin to fill their brood-chamber, look over the combs for any indication of swarming-cells. If you have only full-depth supers, take out two or three frames of brood from below, replacing them with full sheets of foundation, and fill out the empty space in the super with empty combs or full sheets of foundation.

—E.O.]

Following the Swarms

My house is situated on a site overlooking the beautiful Connecticut River at Holyoke, Mass. My yard extends back from the house about 200 feet to the brink of a deep ravine with very steep banks. I had three colonies of bees in my yard.

After dinner I was busy near the house when my attention was called to the bees by three painters who were working for me. I at once saw that I had an early swarm going off, and followed them as well as I could out of the yard and down the bank of the ravine. The foliage was so thick on the trees that I lost sight of them but could hear them humming. After a time I succeeded in seeing the cluster of bees up in a maple-tree about 70 feet above the house. The tree grew at the very bottom of the ravine.

I knew that I could not climb up to reach them, so I returned to the house and asked two of the painters, who were young fellows about 18 or 20 years old, if they would assist me. They were only too glad to have the diversion and experience.

We took down a hive filled with empty combs in

frames, a cover, a bottom, and a sheet. One young man climbed up with a handsaw hung in his suspenders, and had gloves and bee-veil on. After a hard climb he succeeded in reaching a position where he could saw the limb off, but he could not hold it. Its length and weight, with the bees, was too much, and he had to drop it. The two of us underneath received a shower of honey-drops. The few bees that reached the ground quickly joined the swarm in the air.

Soon they commenced to cluster again on a limb of a tree near by; and after waiting for them to settle, the other lad tried his luck at it but with the same result. After the second tumble they formed again on the first tree, and the first man tried again, but with no better success. Once more they were all in the air.

While we were watching them we noticed that they were alighting on the lad's hat in numbers, and soon they began to cover his hat and veil. I advised him to keep still as long as they were not angry and did not sting him, which he did. When most of them seemed to cover his head completely I told him to come down carefully and not jar them any more than necessary and I would shake him in front of the hive. After he had descended very slowly we had to lead him to the hive, since he could not see through the cluster of bees. We had him place his head on the sheet. Very soon he drew out of the hat and veil and we had the pleasure of seeing them march into the hive like a drove of sheep, and the young man did not get a sting.

While we were intent in our watching the bees enter the hive we did not give any thought to the remainder of the bees in the air until one of the men happened to look up. He exclaimed, "Well, we haven't all of them—look there!"

Sure enough, there was a cluster of good size away up high, enough to be a swarm of itself.

So the fourth climb was made, and I went to the house and secured a rope to let them down by. We were successful in this method, and had more fun in seeing them also go into the hive in orderly manner. About 6 o'clock we carried the whole outfit up to the yard. My new colony went to work the next day in earnest.

Holyoke, Mass.

CYRUS H. TAFFER

What Causes the Bees to Ball their Queen Every Time the Hive is Opened

I have about thirty hives of bees, or nuclei. Last year I bought a few queens and introduced them with smoke with very good success; but when I would go to open the hive to see if they were laying, even after a week or two weeks, they would ball the queen, and oftentimes kill her if I was not very careful. I thought it was on account of the dry weather, for they used up all their honey, and some of them I lost on account of its being so dry.

This year they have been able to gather white-clover honey pretty steadily, and yet they seem to want to ball the queen—not in all of them, but in a great number, when I went to look through.

Last Saturday I smoked one hive, which covered five frames with brood and honey, and took some empty frames out in a hive-body above the one I had placed there to keep the worms out; and when I went back to get more frames they had the queen balled; and at other times, after giving them a puff or two of smoke, and lifting a frame up, they would start after the queen and ball her. I have known them to be laying, and on going through the hive the next time the queens would be gone and queen-cells started. They do not seem to want to sting me, but only the queen.

New Castle, Pa., Aug. 9. JAY C. WHITE

It is not clear to us whether this trouble of balling the queen every time the hive is opened is confined to one colony, to several of them, or to all of

them. Sometimes the trouble is undoubtedly due to the queen, and at other times it is due to the peculiar temperament of the colony. We have known colonies (but the cases of them are very rare) where, several times, when the hive was opened, the bees would ball their queen. Apparently disturbance annoys them, with the result that they seem inclined to lay all the blame on the queen. But it is seldom that such balling results in the death of the queen. We have known of other cases where the queen was so timid that, no matter what colony she might be in, she would squeal when the hive was opened, and the bees would proceed to ball her. A queen that shows fright, and tries to run, is much more liable to be balled than one that acts in a perfectly natural and normal way.

If several of your stock show this balling tendency, then we should look back to a common origin—that is to say, back to some grandmother that was the mother of the queens in those several colonies. When the old bees die off the trouble should disappear.—Ed.]

A New Hive-stand

I am illustrating a model of a device which I am using for a hive-stand. I think it is particularly well adapted to city apiarists. The bees seem to like it. Painted green, it has a clean and substantial appearance and gives a finished look to the hive, which is not the case with hive-stands generally.

The entrance is under the hive.

The entrance being back and under the hive, the guards are not annoyed by objects passing the hive, thereby reducing the danger of stings. As the entrance is under the hive, the stand also forms a portico; and in bad weather the bees fly right in out of the wet.

Toledo, O.

T. J. FROST.

Never Again an Aster

My bees are not in as good a condition as usual or as I could wish. The situation is due largely, I believe, to aster winter stores, coupled with cold, wet, high winds in the spring. I shall not winter my bees again on such stores.

I never had hives so spotted before nor so much aster honey as last fall.

Ellwood, Ind.

A. I. Root

OUR HOMES

Editor

And Pharaoh said, Who is the Lord, that I should obey his voice to let Israel go? I know not the Lord, neither will I let Israel go.—EXODUS 5:2.

At our Thursday prayer-meeting our good pastor informed us a request had been made that our prayer-meetings between now and the Ohio election on Nov. 2 be devoted more or less toward the work of making Ohio dry. I do not know whether all denominations aside from the Congregational are requested to act in harmony with the above; but God grant that it may be so.

I presume our readers are sufficiently acquainted with the book of Exodus so that I do not need to tell the story in detail. The Israelites were groaning under the oppression and bondage put on them, and Jehovah heard their prayers and commissioned Moses to intercede for God's people. Moses was reluctant to undertake the task. He probably feared he would lose his head as soon as he made known his request, and our text is Pharaoh's reply. Like the kings of the present day—at least most of them—Pharaoh was proud and stubborn, and said, "Who is the Lord, that I should obey his voice?" Now, if kings and princes only, stood up against God's command it would be a better world than it is now. While I am loyal to our good president, and thank God almost every day that we have a Christian man at the head of our nation, I still have reason to feel that this Christian man is not permitted to have his way in some things. As I write, the whisky party still rules over us, and with its millions of ill-gotten gains defeats us again and again as Pharaoh apparently defeated Jehovah again and again. In order to make him let the people go, Moses, by God's command, turned the river Nile into blood. Then Pharaoh finally gave up and promised to submit to Moses' request. But he forgot or *ignored* his promise. Next came the plague of lice and flies, but with apparently no better results; then the plague of boils and blains; the plague of hail; the plague of locusts and of darkness. But Pharaoh was still contrary and ugly. Last, but by no means least, was the slaughter of the first-born. Then Pharaoh apparently gave up and told Moses to get out of the way with his people. I presume likely Pharaoh had some wicked counselors—some who were in league with Satan just as the United States of America has *some* such counselors just now. They told Pharaoh things would be in bad shape without the Israelites for servants. Perhaps they suggested that these troubles

in the past had all gone by, and poor foolish Pharaoh, blinded by Satan and Satan's allies, rushed to destruction, and God's people *rejoiced* over the miraculous deliverance. I hardly need say to the followers of the Lord Jesus Christ and to those who love truth, honesty, temperance, and purity, that a *Pharaoh* is standing over us right now in this twentieth century, and loading us with grievous burdens—burdens that we have brought on ourselves because we have "forsaken the living God," and are letting idols of various sorts come in between us and our heavenly Father. Punishment has come again and again in times past, and we as a people repent and reform for the moment, but soon become so busy with our idols that we drift back again.

A few years ago a great school building full of children was burned up in Cleveland, and such a reform was started in the way of better arrangements for schoolchildren in the case of fire that even away down in Bradentown we were roused up. As soon as I saw the account in the daily paper I remembered a two-story school building in sight of our Florida home; but almost before I could bring the matter up in our prayer-meeting the carpenters were at work fitting up good substantial outdoor stairways—two of them; and I believe such was the case over nearly all the United States. Much as the fathers and mothers of our land love their children, they had become stupid and forgetful. Another disaster in Chicago taught the whole wide world, almost, the folly of having the doors of public buildings swing inward, so that when a panic occurred the doors could not be opened. Just now, go where you will, you will find the doors of such buildings open outward, and there are plenty of exits also. I believe the laws of our land demand it. "Safety first" has become a watchword; and there is some dispute as to who first started it. The great Pennsylvania Railroad Company claims to have originated the idea some eighty years ago, as you will notice further on.

When the Titanic disaster occurred, I said, just as soon as we got the first particulars, that *whisky* was at the bottom of it; and we soon had facts, if you remember, to show it, but the truth was carefully suppressed and covered up. England did not relish the idea of having it go abroad that her partiality for beer or strong intoxicants lay at the bottom. I believe a careful investigation has been made, and the entire

passenger-carrying vessels of the great ocean have been overhauled and looked into better than ever before. I have not learned yet, however, that England has made any such law or rule as Secretary Daniels has at the head of our navy.

And now we come down to the Eastland. I said as before, as soon as I got the particulars, that it was *Chicago beer*, and the Chicago fashion of having it on board our *excursion steamers* that was at the bottom of *this terrible disaster*; and, as with the *Titanic*, it seems our daily papers generally have been induced to keep the full truth out of sight. Our Anti-saloon League organization, however, is not afraid to let the people have the truth. See the clipping below, from the *New Republic*, published at Westerville, Ohio:

EASTLAND DISASTER REVEALS SCANDAL.

That promiscuous drinking, gambling, suggestive dancing, and general immorality was permitted on board the ill-fated Eastland and other excursion boats running out of Chicago, is the conclusion of the investigators for the Juvenile Protective Association, within the last few weeks.

The report further reads:

IMMORALITY.

Conditions bad; young couples embracing publicly; liberties taken; staterooms used frequently under suspicious circumstances; men and women of doubtful character mingle with girls for purposes which are not considered good.

Two of the engineer's force were drunk, and one passenger passed two bottles of beer to the engine-room. The watch was right there and saw this, but did not interfere.

Four cases of drinking were noticed on the upper deck, two of the parties being minors (motorcyclists). Two other young fellows were intoxicated also.

The girls who did not appear to be 18 drank beer. Beer was sold in two places. There was a regular bar in the front of the hold. There was another bar in the rear of the hold. Beer was sold on the floor below the dance-floor.

Here is something more from the *Plain Dealer*:

BLAMES BEER FOR UPSET.

It wasn't the crowded condition of the Eastland that caused it to topple, and it wasn't faulty construction of the boat, according to one survivor of the disaster who has communicated with investigators. It was the falling of a three-ton refrigerator filled with beer, he argues.

"When the refrigerator upset, the boat began to list," he said to-day.

You will recall the management of the boat was severely censured, or *is* to be censured, for having the apartments that contain the water ballast empty—especially at a time when it was so very much needed.

From the above we see that two of the engineers were drunk when the women and children were overloading that great vessel. Very likely it was the business of *these two* to see that the ballast was safe and correct for such a time, and properly cared for.

There has been quite a little argument,

pro and con, as to whether our labor unions should vote wet or dry. May God be praised there is at least one journal—the journal that represents the blacksmiths, that is not afraid to speak out.

A LABOR JOURNAL HITS THE SALOON.

Our lawmakers have legalized the whisky business (and one of the most inhuman combinations known to man is the Whisky Trust), and made our national government a partner in the business. It seems strange that, after tracing so much poverty and crime direct to the saloon, the American people do not rise *en masse* and obliterate it from the face of the earth. No one who keeps pace with the times can deny that the saloon is responsible, either directly or indirectly, for nine-tenths of this poverty and crime. No one can deny that it is whisky that has made the coward a demon who took the life of his fellow-man. No one can deny that in nearly every walk of life its baneful influence can be traced from the United States to the almshouse and the penitentiary. No well-advised trades unionist can deny that a greater part of the internal quarrels and bickerings among trades unionists have been concocted in the back rooms of saloons. The greatest curse to the labor movement has been the saloon, and it is high time that the labor leaders get together and forever divorce the trades union movement and the saloon influence.—Editorial in *Blacksmith's Journal* for December.

"GOD GIVE US MORE SUCH JUDGES."

Just of late good people have lamented the fact that we have even judges who are on the side of the wets; but, may God be praised, the judges, (at least *some* of them) are "coming our way." The following was sent us by Miss Minnie J. Ellet. She puts on the heading.

JOHN BARLEYCORN, A DESTROYER OF HOMES, HAS CAUSED 200,000 DIVORCES IN THE UNITED STATES IN TWO DECADES.

By William N. Genmill, Judge of the Municipal Court of Chicago.

Booze is the mother of crime. It gives life and sustenance to slums, gambling-dens, and "pay-off joints." It nerves to his deed the homicide, the stick-up man, the burglar, the thief, and the thug. It fires the brain of the prostitute and the panderer. It feeds and inflames the passions of the weak-minded and the degenerate.

I have tried an army of 50,000 human derelicts, most of whom were booze-soaked. With faces red and bloated, with eyes dull and languid, with bodies weak and wasted, with clothing foul and ragged, this vast army is forever marching with unsteady step to the graves of the drunkard and the pauper or to the prison and workhouse.

I have looked into the tear-stained faces of a still larger army of fathers and mothers, brothers and sisters, wives and husbands, as they have pleaded for the miserable wrecks that booze has made. I have seen with this army ten thousand pale-faced, hollow-cheeked, ragged, hungry, and starving children, cursed by booze.

A BREEDER OF CRIMINALS.

I have observed that every bandit crew that goes forth to murder starts from a saloon; that every panderer has his rendezvous in a grogshop; that every den of thieves makes its victims drunk before it robs them; that every house of prostitution has its bar or is in partnership with booze; that every gambling-den either is in a saloon or sustains a close relationship with one; that the pickpocket "trust" is housed in a saloon; that the "pay-off joint" for

the crook and the crooked policeman is in a saloon; that the professional bondsman and character witnesses for thieves and holdup men are saloonkeepers or bartenders.

Booze has caused 200,000 divorces in the United States in the last twenty years, and adds 25,000 more to this number every year. It divides more homes, fills more jails, and empties more churches than all other influences combined.

Judges, legislators, mayors, governors, and even presidents sit dumb or quail in the presence of this monster which enters millions of homes and leaves them desolate.

I have witnessed daily its ravages after it has spent its wild fury upon the helpless bodies of women and children, or after it has reaped for a night, in the public dance, its harvest of virtue, now dead forever. I have observed that the last man to be employed and the first to be discharged is the victim of booze.

Booze never built a park, a playground, a school, or a church, but is the enemy of them all.

War may be hell; but where it slays its thousands booze destroys its tens of thousands.—*Chicago Herald*.

The way in which the various railroad companies are coming out for prohibition is certainly a cause for thanking God. Below is something that, if I understand it, applies to all the railroads in the United States, or pretty nearly all of them. Read it, and thank the Lord for it when you get through.

I have before made allusion to the Pennsylvania Railroad Co. The following, which I have clipped from the circular the Pennsylvania road is sending out, ought to be given to temperance workers for their encouragement:

AS TRAINMEN SEE ALCOHOL.

(From the *Railroad Trainman*, official organ of the Brotherhood of Railroad Trainmen.)

Railroad men throughout the United States have received a document dedicated to "the well-being of the general public." It is from the pen of a "safety first" advocate. It is a New Year's pledge, circulated by the Frisco system. Summarized it is as follows:

"Alcohol: It is bad company and unsafe to be with. It throws switches wrong; it reads orders wrong; sends orders wrong. It receives orders wrong; it calls red white; it never calls white red. It makes caution orders without effect; it makes slow flags without color.

"It makes one meeting-point another. It makes wakeful men sleepy.

"It makes duties dangerous, hot boxes cold, rough journals smooth. It makes pilots and footboards deathtraps. It makes good men bad men; it makes two limbs one, and it makes widows and orphans. It is against safety. Unsafety is its name.

"Statistics show that it has killed more people than all the wars of the world since the dawn of history.

"It has been said and proven that it sank the Titanic."

THE PENNSYLVANIA RAILROAD SYSTEM: INFORMATION FOR EMPLOYEES AND THE PUBLIC.

The Pennsylvania Railroad System carried approximately 160,000,000 passengers in the year ending June 30th, and not one was killed in a train accident.

The feat of carrying about half a million passengers (on 26,196 miles of track) every day without a single serious mishap cannot be attributed to mere

good fortune.—Philadelphia, Pa., *Press*, July 13, 1915.

WHERE "SAFETY FIRST" REALLY STARTED.

Many people and railroads claim to have started the "Safety First" movement. To prove its right to this distinction the Cumberland Valley Railroad—a part of the Pennsylvania System—quotes from the Minutes of a meeting of the Board of Directors held in 1828, which said:

"The following preamble and resolution were offered by Messrs. Berlin and Watts, and agreed to, viz.:

"This Board deem it a consideration of the first importance that every possible precaution should be taken for the protection of the lives and safety of individuals traveling upon our road, and that, as a primary step to the attainment of his object, habits of intemperance should be discouraged in all persons who have any connection with conducting business of any kind upon the road. Therefore,

"Resolved, That no person shall be employed or continued in the service of the Board whose habits of intemperance, either permanent or occasional, are such as to hazard the safety of passengers upon the road or property carried upon it—and that the Board hereby charge the Chief Engineer and his assistants with the special duty of enforcing attention to this resolution."

From the above you will notice the management of this road has firmly shut down on all employees who even *occasionally* get drunk. Let us patronize the Pennsylvania whenever it is possible to do so.

Our daily papers are also coming along slowly into line with God's wishes and God's commands. We can rejoice also, and thank God, for what the leading physicians and boards of health are doing. Read the following:

Since January 1, 1915, twenty-four daily newspapers, according to the records of the Temperance Society of the Methodist Episcopal Church, have barred from their columns liquor advertisements. This is in addition to the 520 newspapers previously reported to have eliminated liquor advertising.

SALOONS PROMOTERS OF DISEASE

Indiana's Board of Health will fight the evils of alcohol. The legislature of 1889 passed a law making it unlawful "to maintain any conditions whatever which may transmit, generate, or promote disease," and gave the Board of Health full power to enforce that law.

The board is now considering closing the saloons in Indiana as "promoters of disease." That means progress, whether the attempt to close the saloons succeeds or not at this time. It will finally succeed, and each battle puts us further on the road to victory.—*New Republic*.

The suggestion in the above, that the saloons in Indiana are "promoters of disease," is almost a joke. Now, here is a clipping below that I hope may, through God's providence, get into the hands of the English people. Is it really possible that England thinks more of her beer than she does of the perpetuity of the English nation? Let her answer.

England stands before the civilized world in the position of having her affairs ruled by an interest so selfish that it prefers German success rather than lose the profits on beer and whisky.

The number of drinking-places in France is so great as to astonish Americans. Paris has a drink-

ing place for every 40 adults. In comparison with the population Paris has 11 drinking-places where Chicago has four and New York has three.

The situation in prohibition Russia is known to the reading world. The remarkable change which has come over that country is one of the wonders of the early days of the twentieth century. On the whole, the people themselves like the change, commend the Czar for his prohibition decree, and declare that so far as drink is concerned it was a happy day for Russia when the Germans declared war.

The one fact that the \$500,000,000 formerly received by the government in one year from liquor revenue is now more than balanced by the increased sums deposited in savings banks, shows that prohibition has brought prosperity and happiness to the Russian Empire, even if it did not bring peace.—*American Issue.*

My good friends, I have been giving you a lot of discouraging facts in the above. Of course there has been something encouraging, more or less, in most of them; but here is something on the other side; and may God be praised for what poor suffering Russia has done in the way of lifting the grievous burden of drink from the shoulders of her sons and daughters.

In concluding I wish to give a brief clipping from our friend Ridgeway, in his "Business Men's Corner" in the *Sunday School Times*. Read it, and see if you do not think it is a fit winding-up for this Home paper.

Every time Dick Strode's mules had to be shod they always had to be thrown and banged around and tied up. They never learned who were their friends, and were always trying to "kick the stuffin' out of things," as Jake the blacksmith used to say. This is the way God sometimes has to "shoe" his mulish children.

Is it not true, dear friends, that God in his loving kindness has really been obliged to treat us or to treat humanity as Jake the blacksmith treated the mules? We have noted how He dealt with Pharaoh, and how stubborn and contrary the king was when God's only purpose was to let his chosen people go out of Egypt and into the promised land—a land that was literally "flowing with milk and honey." Good men and good women have no doubt protested because the people who are responsible did not make better provision to save the lives of comparatively helpless schoolchildren; and finally this awful punishment—an object lesson that the whole wide world will remember—was permitted to come first to wake us up.

Just now I am rejoicing at a movement that is being made to take care of the babies; and the great city of New York just now stands at the head. They have taken such care and pains to provide pure milk, and competent doctors and nurses to instruct the mothers, that the death-rate among the babies is less than in any other

city in the land. Ever since the time of Noah, prophets and preachers have been warning us against the consequences of strong drink; but that blacksmith's journal says our law-makers have legalized the whisky business, and caused the most inhuman combination known to man—the whisky trust—and made our national Government a partner to it. Our kind and loving heavenly Father has sent us disaster after disaster, and yet our nation is *still* a partner to this hellish business, and, at least to a great extent, is saying to the voters of Ohio and to the voters of the United States, and, I fear, to the voters of a great part of the world, "Who is the Lord, that I should obey his voice?"

As a fitting closing to this matter we submit the following from Miss Ellet:

If Christian Ohio awakes, and prays for victory, and works for votes we'll win. We can't do it without God, and he will not do it without our best efforts. When it's true in Ohio, that "they that publish the tidings are a great host," old Demon Rum will run down a steep place and be drowned in the sea of his own iniquity. "This is the victory that overcometh the world, even our faith." Casting out demons cometh only by prayer and fasting—sacrifice. MINNIE J. ELLET.

Rt. 21, East Akron, O., Aug. 21.

"BAMBOOZLED BY BOOZE."

I have several times of late thanked the Lord for our splendid farm papers, and especially for the fact that they stand almost all, if not quite without exception, for righteousness, temperance, and purity. Just now I am thanking the Lord for the periodical called *Successful Farming*, published by the Successful Farming Publishing Co., Des Moines, Ia. This periodical is in its fourteenth volume, and I am thanking the Lord *again* that it has more than 700,000 subscribers. Do you want to know why? Well, it is because of an article in its issue for March, entitled "Bamboozled by Booze." This article was compiled and written by a son of our long-time friend and poet, Eugene Secor. It is the best summing-up I have ever come across of the ridiculous and shameful plea the liquorites are putting out, that the whisky business helps to pay our taxes. The figures and conclusions are such that there is no getting around it.

Here is an editorial in the same issue that sums up pretty well the article.

WEIGHED AND FOUND WANTING.

The liquor business has been weighed in the balance and found wanting. This is no new discovery on the editor's part; but after putting in one pan of the balance the annual drink bill of almost three billion dollars, one has to put in the other pan such an enormous quantity of good, wholesome, and useful things to balance the scales that every one will agree to the old, old fact that the liquor business doesn't pay.

But you will be told all about it—or as much as you can probably comprehend at one reading—in another article which appears on page 9 of this issue. It is real interesting work—weighing 2,128,452,226 gallons of booze. Whether you are a tippler or a teetotaler you will surely read it with amazement and profit. It makes your tax problems look like thirty cents! Think of it—a hundred and ten thousand drunkards die every year. And we put up a hundred and ten thousand boys every year to fill their places. Would you rather sell two per cent of your grain—that amount goes into the making of booze—or push one hundred and ten thousand boys over the cliff into a drunkard's grave?

Read "Bamboozled by Booze" and learn how you cannot only save those boys but sell your two per cent of grain too. This is business—not wishy-washy sentiment.

Just think of it, friends—and it is really true—we as a nation are actually "pushing 110,000 boys every year over the pit into drunkards' graves," with the absurd and ridiculous notion in our mind that the money we get for so doing helps us to pay taxes or makes our taxes lighter. "What shall it profit a man if he gain the whole world and lose his own soul?"

Later.—Since the above was put in type we have received the following letter:

Dear Mr. Root:—My father told me that you were pleased with my article on "Don't be Bamboozled by Booze," which appeared in *Successful Farming*. There were so many calls for this that we reproduced it in pamphlet form, one of which I am enclosing. I shall be glad to have you use this in any way that will help you in your state fight.

SUCCESSFUL FARMING,
ALSON SECOR, Editor.

Des Moines, Iowa, August 18.

The entire article equals about three pages of *GLEANINGS*, and may be had of the Successful Farming Publishing Co., Des Moines, Ia., at 35 cents per 100.

WHISKY AS A MEDICINE.

May the Lord be praised that the day is so rapidly going by when whisky is considered a remedy for snake-bites, or any other kind of "bite," for that matter. Our most intelligent physicians have been for some time past coming to the conclusion that whisky, brandy, and all other intoxicants are not only of no real value as a remedy, but they say "the remedy is worse than the disease." We clip the following from *The New Republic*:

DR. WILEY'S FINAL VICTORY.

At the present time, the publication committee is engaged in the regular decennial revision of the *Pharmacopœia*, and Dr. Harvey W. Wiley is the chairman of the revision committee. On the committee are 51 representatives of the medical societies and medical colleges of the United States. The surgeon-general of the Army, the Surgeon-General of the Navy, and the Surgeon-General of the Marine Hospital Service, are ex-officio members of the convention, but not necessarily members of the publishing committee having the work of revision directly in charge.

When this committee came down to "spiritus frumentii," the technical name for whisky, there

was a great row. The admirers of President Taft and followers of the rectified-whisky crowd were determined to revise the historic formula of the *Pharmacopœia* so as to conform to the decision of President Taft, and recognize almost any old thing as whisky that would bring the drunk and bring it quick.

Against this idea, Dr. Wiley and his supporters stood like a wall for the standard whisky that had been the standard for nearly a century.

The contention waxed fast and furious among the dignitaries until finally they reached the conclusion that whisky is not a much used medicine anyhow, and they might as well dump it out of the *Pharmacopœia* entirely. They finally agreed upon this, and both whisky and brandy will not appear in the forthcoming National *Pharmacopœia*.

"We don't use whisky as a medicine anyhow, and there is no more use of fixing a standard for whisky than there is fixing a standard for garbage," declared one of the wise men.

SHALL WE KEEP ON VOTING IN "THE SAME OLD WAY"?

The following clipping, source unknown, was mailed us by a friend of *GLEANINGS*. What do you think about it?

Stephen Lukovitch, of New York, went home drunk and cut his three-year-old son Louis seventy times, making him the worst-mutilated lad in the world. The child will recover, but will be disfigured for life. You shudder at the thought; but did it ever occur to you that you vote to make possible just such outrages as this when you vote to permit intoxicating liquors to be sold where you live? Felonious assault, murder, and practically every other crime, can be traced to the door of intoxicating liquor, and this will be true as long as the stuff is permitted to be sold.

RAISING THE BANNER OF TEMPERANCE, AND HOW THEY DID IT.

We have fought the wicked booze business to the last ditch, and have won—not by a very great margin, but by enough to serve all practicable purposes. We now pride ourselves as being among the first states to raise the banner of temperance, not merely because it is an achievement to do the right thing, but because it is an achievement to do the right thing when faced by huge unfair obstacles such as confronted us.

The liquor league this year realized that they were losing power, and must regain a footing by any means whatsoever were they to hold their own in the coming election; so they were forced to resort to deception, for Fairness turned her back on them. They posted unfair comparisons of every description between "dry" and "wet" states, some of which were so disgustingly simple as to make one wonder how people of intelligence could be swayed by such argument. The bartenders circulated false statements regarding the articles of the prohibition or initiative measure, thus robbing us of many votes, and, above all, the anti-prohibitionists went about destroying our literature and posters.

Notwithstanding all of this, we defeated them. A number of high-school boys volunteered to carry prohibition signs in front of the polling-places, and others distributed "dry" literature, so that an excellent showing was made. This city of Pasco, long notorious for her vulgarity, and known far and near as the home of the vices, rallied its best citizens and voted "dry" by a good majority. This was a surprise to thousands, and was brought about only by church organizations and the determined efforts put forth by a number of our prominent men, notably Prof. E. M. Dorsey, principal of the high school.

We are sympathizers in your struggle to put the Anheuser-Busch and Schlitz out of business, and to give the boys and girls of America a better opportunity.

Pasco, Wash., Nov. 11. GEO. ROGER CHUT.

OHIO'S SHAME, ETC.

The following was written last November, shortly after our Ohio election; but I have given it a place, thinking it will apply very well to the condition of things now as well as a year ago.

Shame on Ohio's election, and more shame on Tennessee, my old home, for not re-electing the governor. May God show them their mistake.

Why do you not tell some of those people who favor liquor license that it would not cost so much to pay for running the county with a less number of judges, courts, jails, poorhouses, and hundreds of other unnecessary institutions? And how may children would be happy with their mothers, glad to see the father and husband come home with his pay check not cashed. I have learned to believe that doing away with grafting (called business) would stop the sale of liquor or war, and make heaven on earth with all nations brothers.

Minneapolis, Minn., Nov. 24. L. E. WALLACE.

HIGH-PRESSURE GARDENING

"HIGH-PRESSURE GARDENING" WITH A MORAL.

For some years past I have been watching the movement for utilizing the vacant lots in our cities; and just now somebody has been kind enough to send me the following clipping from the San Francisco *Examiner*. May the Lord be praised for the good men and women who started this beneficent ball rolling.

CITY FARMING MAKES MONEY AND MEN.

There is a small group of men in Philadelphia who believe in the precedence of human rights over all property investiture, and for eighteen years Philadelphia, through its Vacant Lots Cultivation Association, has not only led in practical results, but has served as a source of inspiration for the founding of similar movements in France, England, and Germany.

The association prepares the idle land, which is loaned to them (subject to dispossession when the owner wants it) for cultivation by plowing, etc., then dividing it into gardens of about one-sixth of an acre. Fertilizers and sufficient rich seed to insure a successful start are furnished the gardeners, which cost the association about \$5 a garden. For these they charge \$1 for the first season, \$2 for the second season, and so on until the family pay the full cost of that which the association furnishes them. The families spread the fertilizer, plant the seeds, cultivate the growing crops, gather the produce, and, after supplying their family needs, they sell the surplus that remains.

Last summer 603 families were allotted plots covering 81½ acres. These diminutive farms on city land, which otherwise would have produced nothing but weeds and rubbish piles, and, in addition to being disfigurements, would have been breeders of disease, have provided about 3000 men, women, and children with a most healthful exercise, an instructive form of occupation, and materially aided in reducing the high cost of living.

The cost of cultivating these lands was \$7693; the food produced was valued at \$32,000—\$4 for every one invested—and all the profits went to the workers, who earned the help given them.

This back-to-the-land movement is the best form of progressiveness, and surely that man must be dead to all sense of social responsibility who will not loan his idle lands as instruments for self-support, better habits, practical education, and real happiness.

The largest profits of this non-pauperizing plan cannot be figured. It is not a charity; it is social justice—an opportunity for those in need to help themselves by their own work.

In addition to providing food and the wherewithal

for supplying other vital needs it furnishes the only opportunity for physical and moral growth under right environment.

"The greatest value our little garden brought us," said a Frenchwoman shortly after a Philadelphian had introduced the plan in France, "has not been in the fine vegetables it yielded all summer, or the good times that I and the children have had in the open air, but in the glasses of beer and absinthe my husband hasn't taken."

"Quite right, mother," said a man standing near by. "No one can ever know the evil we men don't do while we're busy in our gardens."

The total number of vacant parcels of land in the city of New York for 1914 was 193,000. The total for Brooklyn was 50,391. These parcels, often no more than an ordinary building lot, sometimes comprise several acres. It is safe to say that there are upward of 250,000 idle acres within New York's city limits. These could produce, if the same returns were made in New York as in Philadelphia, \$400 an acre, which would mean \$100,000,000, and a net profit of \$75,000,000. Thus, to use these vacant lots, which are now eyesores and nuisances, would not only be making something out of nothing, but give to thousands of families the truest relief—the opportunity to help themselves to procure a livelihood.

There is one point in the above, and, in fact, in everything I have ever gotten hold of on the subject, that seems to be overlooked. Any piece of ground, no matter where it is situated, would certainly be worth more if it were occupied by a neat pretty garden than by an accumulation of rubbish, foul weeds, etc. Now, cannot the owner of this vacant lot afford to pay something for having it transformed into "a thing of beauty," instead of being an eyesore to the residents and passersby? May God speed the movement.

STRAWBERRIES IN 90 DAYS AFTER SETTING OUT THE PLANTS.

On page 692 I mention red raspberries that grew and matured quite a crop within 80 days after planting; and just now in the *Ohio Farmer* I find something that pretty nearly matches it in the way of strawberries.

EVERBEARING STRAWBERRIES.

If we had been told ten years ago that the time would shortly come when an abundance of strawberries could be gathered from plants set less than three months before, we would certainly have thought the prophecy unsound. But our eyes have seen and our ears have heard the fulfillment of such a prophecy.

At the meeting of the Portage Co. Horticultural Society, held on July 21, Mr. W. B. Nichols exhibited a box of strawberries, very uniform in size and shape, being globular and about one inch in diameter. In answer to questions he said: "The vines that bore these berries were transplanted in April of this year. They were set in good soil which was cultivated well and continuously. The runners were cut off and the blossoms picked as soon as they appeared. To do this required constant daily attention, for a runner will grow three or four inches in a day. They are of the Superb variety of the ever-bearing class. The picking of the blossoms ceased three weeks ago and the result is before you. I have demonstrated," he said, "that I can grow ripe strawberries in abundance within three months after the setting of the plants, which is in marked contrast with the June-bearing varieties, which require at least 14 months to secure good results. To get the quick returns demands fertile soil, good and continuous culture, and the prevention of the natural setting of new plants. All effort must be given to the rapid and healthy growth of the individual plant so that when the fruiting time arrives its undivided attention may be given to the production of berries."

Will it pay to give such careful attention to grow the strawberry out of its so-called natural season? It is one of the most universally liked berries that are grown, especially in the fresh state. It is quite difficult to preserve it in anything like its original form and flavor for any considerable time. That there is an active demand is evidenced by the fact that at times during the late summer and fall months the supply of fresh berries has not equaled the demand at 40 cents and more per quart.—C. H. SAPP, Portage Co., Ohio.

I confess I have always had a liking for things that grow quick. When some of the catalogs advertised different seeds that would give radishes large enough to eat in 21 days from the time the seed was sown, I thought it was quite a feat; but on very rich soil, just the right temperature, plenty of water, and good cultivation, I have succeeded in getting very fair little radishes in only 18 days. Now, with the raspberry mentioned, and also with strawberries, you must have very rich soil, well drained, a location that gives free sunshine without any shade from early in the morning till late at night, and, above all, careful attention. I think I loosened the ground around my raspberries as much as a dozen times, breaking the crust, and digging it up after every rain. But to get strawberries in 90 days we must make up our mind to give them good care.

After the above was put in type it occurred to me that down in my Florida home strawberries are planted by the acre in September and October; and my good neighbor, year after year, is picking them for market, more or less, in even less than

90 days from the time of setting out the plants; and they usually get a good price for the berries too.

BEEES, FLOWERS, AND COLLEGE GRADUATES.

On page 646, Aug. 1, our good friend Woodberry, in speaking of my visit there something over twenty years ago, says:

"I was a bachelor then, but now have a daughter who graduates from college this spring."

Later on he wrote as follows:

I inclose a picture of our daughter Anna, taken in our garden about six weeks ago. She is standing in front of some sweet peas, and in the background is a castor-bean hedge planted less than a year ago.

I wish to congratulate you and your helpmate on your long and happy sojourn here on earth together. May you both continue to enjoy your blessings to the ripest of ripe old age.

Glendale, Cal.

G. B. WOODBERRY.

Below is the picture.

In a California garden. "Her price is far above rubies."

Now just a word to my bachelor friends, not only away off in California, but wherever they may be, anywhere in the whole wide world. These words are to remind you of the sacred and solemn responsibilities that are resting on your shoulders. Had not friend Woodberry taken my advice twenty years ago, and got a wife in that bachelor's pretty little home, this bright young lady in the picture would never have come from Heaven to earth to bless that earth, and to bless mankind at large. There will never be too many young women college graduates to help stem the tide of intemperance, crime, and wicked war that are just now devastating the whole wide world.

HEALTH NOTES

ROBBING SICK PEOPLE.

One of our workmen told me a few days ago he had something to tell me along the line of medicine. He had been taking a certain kind of medicine all winter long, or nearly so. I do not know whether the doctor advised it or whether he got it at a drugstore; but he thought he needed something, and the directions were to take it regularly for quite a spell before the good effect would be secured. Well, his testimony was like this:

"Mr. Root, I began to think the medicine was doing me harm instead of good, and I stopped right square off; and I have not only felt ever so much better ever since, but I commenced gaining in weight right along. The medicine was really doing me an injury every day I took it."

There you have it, friends. This medicine, whatever it was, was unnatural, and kind old Dame Nature was making a protest; and yet he kept on taking it. And it rejoices my heart to notice that our best physicians are gradually giving up the use of medicine. Granting the medicine *does* give relief for the time being, it fills the system with an unnatural drug, and sooner or later does more harm than good. Here is something from Dr. H. W. Wiley, which I clip from *Good Housekeeping*:

A medicine or drug that would work such cures as fresh air is capable of, we would hail with delight; but when we can put our heads out of the window and perform a miracle, it does not interest us. We would rather pay thirty-five dollars for an ozone-apparatus or oxygen-machine and crawl under the covers with it attached to our ankle, then take God's air through our lungs as a free gift.

Although he does not mention electro-poise or oxydonor in the above, he describes those things exactly. Some of you may urge that a remedy that works only on the imagination, like the above, does no harm like drugs, even if it does no good. But, my dear friends, it harms the *pocketbook*, even if it does not hurt the individual. Consider again being humbugged into paying \$35 for a mere toy that need not cost over 35 cents!

In our July 1st issue, 1914, I gave my opinion of chiropractic, and I came pretty near getting into a hornet's nest. Just now I find in our *Medina Gazette* the following:

The chiropractics got a rather stiff jolt from the lately adjourned legislature. By a new law they have been put strictly under the supervision of the State Medical Board, who are to examine and register persons desiring to practice any limited branch or branches of medicine or surgery, and shall establish rules and regulations governing such limited

practice. The fact is, this new law is calculated to put a stop to a whole lot of quackery and quacks.

Another one of our workmen informed me a few days ago that his wife had paid a chiropractic woman doctor over \$100; and he said that, so far as he could learn, she had the same trouble as when she commenced the treatment, and he very much doubted whether she was better in any way. I hardly need remind you, friends, that certain things have a "run." It seems to be a sort of craze to follow like a flock of sheep. May be it is a craze for some new medicine, some new doctor, or possibly a new kind of religion. People make up their minds beforehand that they are going to be helped, and the introducers of this new cult gather in a great lot of dollars before the people wake up to the fact that it is all imagination, and that the new thing gives no real help at all. Statistics tell us that sick and ailing people are being robbed of millions of dollars, and yet this waste of money goes on. The papers are full of it, even now.

Not long ago I told you of an advertisement for training and developing the muscles. The advertiser wanted \$25 for a course of lessons. As I did not bite right away he came down to \$15, and then \$10; and when he finally got down to \$5 I sent the money; and I also told you that I thought the physical exercise every night and morning was really of some benefit. At the same time I suggested that hoeing in the garden would do about as much good. Well, a few days ago one of my grandsons, the boy who is so much interested in astronomy, and one who is now a member of our "Scout Club," brought me a book. This book contains pictures and directions for the same thing that I paid \$5 for. I might have given \$25 had it not been for my past experience with such things. Well, in the little magazine, *Good Health*, from Battle Creek, Mich., they have the same thing from beginning to end; and, to go still further back, a good lady who taught school years ago tells me that at one time they had the same exercise for the pupils when they became tired and restless sitting still so long.

Now, then, let us who love good health, and love honesty as well, watch out and take good care that we be not swindled any more in the way I have described. Let us teach these "pickpockets" who advertise in magazines and papers that their ingenious and falsifying advertising does not "catch suckers" any longer as it did in times past.

Gleanings in Bee Culture

This is Pacific Coast Year

The eyes of the nation are turned toward the empire of the western seaboard with its two expositions and its unparalleled opportunities for travel.

Similarly, the beekeepers of the West, producers of an important part of its wealth, are turning to the two branches of The A. I. Root Company for their supplies.

Californians and producers in other Pacific Coast states who are in the market for supplies are asked to write for catalogs and prices.

Full line of Root goods are carried at both offices. Do not forget those power extractors. Order your cases and cans early.

REPRODUCED BY THE A. I. ROOT COMPANY

While enjoying the splendors of the Panama-California exposition at San Diego this year, remember to inspect The A. I. Root Company's exhibit in the Varied Industries Building. Our concession stands at the right of the east entrance where you can't miss it. It's interesting and comprehensive. See demonstrations of the new friction-drive power extractors. We have another exhibit in the Palace of Food Products at the Panama-Pacific exposition, San Francisco.

NO. 18

EDITORIALS

For several years we worked eight-frame supers on ten-frame hive-bodies the same as shown on page 761 of this issue. The scheme is all right; but it is not so easy to use a ten-frame super on an eight-frame hive, although it can be done.

BEGINNERS, in locating their hives, should be careful where they place them. Sometimes a colony may be set in position on a city lot where it might cause a great deal of annoyance to the owner and to neighbors on either side. See page 762. The entrances of the hives should be so placed that the flight of the bees will not cross the walk or pathway of people going to and from the house and other buildings.

Bees and Squashes

THE attention of the reader is particularly directed to the picture on page 758 of the eight tons of squashes from five-sixths of an acre. While it cannot be proven positively that the bees helped to bring about that big result, the fact that they visited the blossoms in such numbers is rather significant.

The Booster

THROUGH an oversight the advent of the new paper entitled *The Booster* was not noticed by us when it made its modest bow to the public in June. It is edited by George W. Williams, Redkey, Ind., formerly secretary of the National Beekeepers' Association.

Mr. Williams has long believed that the consumption of honey might be very materially increased provided it were properly advertised by the beekeepers themselves. In a paper read before the National convention in Denver he outlined several things that the producers could do to boost the sale of honey. So thoroughly convinced was he that his ideas were correct he began the publication of a paper entitled *The Booster*.

It is not his purpose, he explains, to cover the general field of bee culture, but to devote his attention almost entirely to providing a "better market and insure better prices." The price of the paper is 25 cents a year.

Phillips' New Book

We have just received a copy of a book entitled "Beekeeping," by Dr. E. F. Phillips. We have known for some time that this work was in course of preparation; and a glance at a few pages makes us feel that it is going to fill an important part in our bee literature, especially along scientific lines. We have not had time to review it carefully, but will give it an extended review in a later issue. The price of the book is \$2.00 postpaid. It contains 450 pages.

Our Cover Picture

THE very fine picture of buckwheat shown on our cover was intended for the Sept. 1st issue, as it shows the field described by Mrs. Howard, whose article appears on page 715. Owing to an unavoidable delay at the engraver's, however, the plate did not reach us until too late, and we held it, therefore, for this number.

A field of buckwheat in its prime is beautiful. In a locality where it is grown extensively, the land on every side has the appearance of being covered with snow.

The engraving on page 716 gives a good idea of the detail of the blossom and leaves.

The Ohio Field Meet, Again

ON page 760 we show a photograph of the Ohio field-day meet held in Delphos August 4. For particulars see page 653 of our issue for Aug. 15th. This was one of the most successful field days that the State Beekeepers' Association has ever held; and the fact that so large a number came out on such short notice, without any preliminary notices in the bee-journals, shows that in-

terest in bees in Ohio, especially the north-west part of it, is considerably above the normal. The bees were still gathering honey from the clovers at the time, and the locality was exceptionally good for that kind of field day. It is doubtless true that other field meets will be held in the vicinity.

A Harem of Queens

A HAREM of queens, as spoken of by O. A. Bromfield, page 765, is not an uncommon occurrence with after-swarms. In fact, these little swarms usually have a plurality of queens; but it is an uncommon experience to have several virgin queens living together in harmony among the same bees. When they do this, there is possibly a sort of "understanding" that more swarms will issue, taking with them the surplusage of queens. But such excessive swarming is not a profitable condition in the beeyard, and it is here that the apiarist should step in and stop proceedings.

The Net-weight Law a Blessing and not a Curse

WILLIAM VOLLMER, in this issue, says he is in favor of the net-weight law as it stands, even in reference to comb honey. While the wrapping around hams weighs from 3 to 4 ounces to 10 lbs. of meat, the section around comb honey as he says is one ounce to every ten or more ounces. Relatively there is a big difference. We can agree with our correspondent that the net-weight law is all right as it is. All we need to do is to adjust ourselves to it. While it may impose a hardship at first, it will necessarily result in a higher quality of comb honey, better filling, and a more uniform product.

Conclusive Proof that Bees are Killed by Spraying

J. E. CRANE, in his department in this issue, furnishes some rather conclusive proof showing that bees are actually killed by the use of arsenate of lead so commonly used in spraying fruit-trees. The bees were gathered up by the handful and sent to Dr. E. F. Phillips, of the Department of Agriculture, and an analysis shows an abundance of arsenate of lead in the dead bees.

There have been many reports of bees dying as the result of spraying; but only two or three that give such conclusive evidence as this. The fact that the bees are killed sometimes, at least, makes the spraying of trees while in bloom unsafe at any

time. It should, therefore, be condemned not only by beekeepers, but by experiment stations and fruit-growers alike.

Clover Prospects Next Season

THE weather maps show that the rain-almost-every-day proposition in the clover belt is giving way to sunshine and hot weather. Our bees have started gathering honey from the asters, goldenrod, white, alsike, and red clovers. Mr. J. E. Crane elsewhere suggests that this peculiar season has not been duplicated before since 1865 in the days of Father Quinby.

If, perchance, the rains should continue through the fall, there will be an abundance of clover next spring. As there has not been a larger fall of rain in inches this year than normal it is not at all likely there will be a drouth next spring. If we have ordinary conditions we shall have a record-breaking clover season next year. Clover thrives when the rains are light and often.

The Spread of Blight Among Fruit-trees due to Puncturing Insects

AS an addendum to our article on page 767 in this issue, on the relation of bees to blight, we may say that later investigations go to show that bees seem to try to avoid the virus of blight. It has also been discovered that there are certain puncturing insects that pierce the bark of tender shoots and limbs of trees. These wounded limbs or shoots are very susceptible to the virus of blight. Many non-puncturing insects such as ants and flies crawling over the blighted portions of a tree will carry the infection to the punctures in the young shoots. This is the reason why so many young trees and young shoots that have never borne any blossoms are so susceptible to blight.

The evidence is accumulating more and more, showing that the bees do not carry blight to the extent that was formerly supposed. Some interesting developments will be made a little later that will go to show that they are in all probability a very small factor in the spread of blight.

A National Honey Day

ELSEWHERE in this issue reference is made to the advent of a new bee paper called *The Booster*. Among other plans to "boost" the sale of honey the editor advocates setting aside a certain day in the year as "Honey day." He suggests Nov. 25 as

an appropriate time, and urges his readers and others to join with him in making Thanksgiving day also a honey day.

Our friend has started out on a big program. While we are a little skeptical about being able to accomplish very much, because the bee papers and their subscribers are only as a drop in the bucket as compared to the great public, yet if we keep at it long enough we may accomplish something. We therefore urge our subscribers to prepare for making Nov. 25 a general honey day in their respective localities. If you are interested, write to Mr. Geo. W. Williams, Redkey, Ind., or, better, secure a copy of his paper, *The Booster*.

Bees and Fruit

THE experiment of placing ripe fruit in a hive to see whether the bees can or will puncture the skins, and thus suck out the juices, as shown and described on page 766 of this issue by Mr. J. P. Lucas, has been tried over and over again, and always with the same result. They will not work through the skin of sound fruit—never have done it and never will do it. But when fruit is overripe, and the skin cracked, and when other insects or birds, or when the spots of skin-rot injure the surface of the fruit, the bees will help themselves most royally.

Just recently we had a pear-tree where the pears ripened within a few days. The skins took on a rosy hue, and this rendered them attractive to the birds. They would make a small hole where the softest part of the pear was exposed; and after a hole was made the bees would keep on sucking out the juices until the skin was a mere shell in some cases.

Fruit with broken skins or holes, made by insects or birds, independent of bees, is, of course, ruined. It would be unfit for market, even if there were no bees. The work the bees do, therefore, does not result in direct damage to the fruit-grower. If, however, the bees "started" the trouble, and then birds and insects helped themselves, the case against the bees would be very different.

Complaints of Queen Advertisers Again

REFERRING to our editorial on page 608, August 1, Mr. Kenneth Hawkins offers some further suggestions that are worthy of consideration, and we believe that reliable queen-breeders will be willing to subscribe to them. Here they are:

My dear Mr. Root:—I believe every queen-breeder's guarantee should be something definite; that he should agree to arbitrate all complaints with the

bee-journal as arbitrator if the customer was dissatisfied with the proposition made, and should not be allowed space at any price unless he would do this. You may be sure those of us who are trying to do right appreciate the stand of your journal in such matters.

Plainfield, Ill.

KENNETH HAWKINS.

We wish to offer the further suggestion that every queen-breeder agree to breed only from select stock. We have been informed that one prominent queen-breeder has been in the habit of using queen-cells from any source—natural cells, good, bad, and indifferent. If a customer could know that the breeder is furnishing him such stock he would buy of the other fellow, without question.

It might not be out of place to suggest that the queen-breeders get together and agree on a set of conditions, not only to raise first-class stock, but to stand by a guarantee and arbitration. We suggest that the guarantee cover reasonably prompt delivery or a statement explaining the delay, an offer to return money in case the customer cannot wait to replace promptly, a sworn statement that there is no bee disease in the yard, and that all queens are reared from the best stock.

A Trick of the Trade in Introducing Virgin Queens

ONE of our subscribers who has been buying some virgin queens writes as follows:

If you will pardon the suggestion, I beg to submit that we beginners should be cautioned more urgently in the matter of supplying a nucleus with a frame of eggs and unsealed brood. I lost two of my last six virgins on this account, I believe. Each nucleus had three full frames of sealed brood and some stores. I made the divisions in the dusk of the evening, because of robbers (these pests give me the nightmare); and while the A B C states very plainly the need of eggs and unsealed brood, I seem to have overlooked it on these two nuclei.

Pittsburgh, Pa., Aug. 3. GEO. W. GUTHRIE.

While our old A B C book does state the need of eggs and unsealed brood, we now believe that it is not an essential factor after all. As a general thing, unsealed brood and eggs help to put a colony in normal condition. Bees that are otherwise discouraged will seem to take on new life.

We have just been talking with our Mr. Mel Pritchard, who has raised some 20,000 queens. He is a very close observer, and he says he does not attach very much importance to the need of eggs and unsealed brood in a nucleus that is about to be supplied with a virgin queen. He has introduced thousands and thousands of them under both conditions, and he does not see much difference if any. But he does say

that the presence of *young hatching bees* does make all the difference in the world. He therefore seeks to avoid having them in a nucleus into which he is letting loose a virgin.

We asked him why they should be the cause of trouble. He did not know how to account for it unless young queens do not know the difference between a baby worker and a baby queen. He has repeatedly seen these young virgins, as soon as let loose, pounce on and sting bees just hatched, one after another.

The trouble apparently arises, not from the young bees, but, rather, from the queen. She starts the trouble, and it is evident that all the bees then take a hand in the fracas, with the result that she loses out as a matter of course.

Why Some Should Advertise at County Fairs

Now is the time for beekeepers to advertise their honey business at local fairs. Live-bee demonstrations and exhibits will draw a big crowd, sell a large amount of honey, and pave the way for future sales. It is the kind of advertising that pays well; and the honey-producer who does not take advantage of it is losing money.

We should hardly expect, however, that an old veteran like Dr. Miller, at the age of 84 years, would give live-bee demonstrations at his county fair. The fact is, he is able to sell his honey, usually, before it is off the hive, at a price that is highly satisfactory, for he sometimes has more than one buyer in prospect—not because he goes after that buyer, but because the buyers come to him. The quality of his honey, his careful grading, and his prominence as a bee-writer, create a good demand for his product. But not all have this reputation; and it will, therefore, be necessary for them to create a demand by letting their local consumers know that they have honey for sale.

A Rose by any other Name

WHATEVER may be the facts in this incident, it points to a fundamental principle in the scientific method, the necessity for exactness in names. A householder cut down four handsome basswood-trees which had shaded his lawn for a generation. He had heard of the linden-tree, its value for shade, for nectar, and for timber, and in his desire to secure some of these he destroyed the basswoods. A nursery set out the lindens according to his order. He was naturally somewhat surprised when, four or

five years later, he discovered that basswood and linden are one.

How often much confusion arises in the discussion of honey-plants, all of which could be avoided by the use of the Latin names, as a contributor has suggested in a former issue. The willow-herb (*Epilobium angustifolium*) is sometimes known as the fireweed. But the evening primrose (*Oenothera biennis*) is also called the willow-herb. Similarly the wild lettuce (*Lactuca canadensis*) sometimes called fireweed. Plenty of room for confusion here.

There are two dog-fennels, one of which is an aster (*Aster ericoides*), and the other *Anthemis cotula*. A variety of sneezeweed (*Helenium autumnale*) and the common field daisy (*Chrysanthemum leucanthemum*) are each sometimes called the oxeye.

While a rose by any other name would smell as sweet, it is likely to cause confusion by any other name than the Latin one. These names are in the language common to science. Latin is to botany and other natural sciences what Italian is to music.

We endeavor to add the Latin names of plants in articles in GLEANINGS where there is a possibility of confusion, but when these are not supplied by contributors we are often at a loss for them, simply because the common name is strange to us, or because there may be several closely allied plants, and we cannot tell which is meant. When a writer attempts to deal with a scientific subject such as a honey-plant, he should use the language of science, the Latin terminology.

The Question of Fall Uniting; When Should it be Done?

It is the usual practice to unite just before putting bees into their final winter quarters; that is, a little before freezing weather sets in; but it has been observed over and over again that a late-united colony is never quite as normal as a regular colony that has sufficient strength without the infusion of other bees. Several united nuclei, if put together late in the fall, look like a good colony at the time of putting together; but very often these combinations die out before spring. For some reason they do not seem to be able to get together as one working unit, like a regular colony.

Every fall we have been in the habit of uniting our queen-rearing nuclei, and this uniting has generally taken place pretty late, because we desired to keep the queens for late orders, even though we might lose the bees that were of much less value than the queen.

Years ago Mr. Doolittle used to recommend uniting in the brood form in late summer. Such a colony will build up normally, and be the equal of any other in the yard, and, what is of considerable importance, there will be no returning of bees to the old stand.

Uniting can be profitably undertaken provided the bees are put together during warm weather. If they raise brood after this, such a united colony will be, to all intents and purposes, the equal of any other.

But why has the general practice of uniting been deferred so late? Queen-breeders do it to save their queens. Others do it because, after cool or cold weather sets in, bees will stay better where they are put, especially if the following week or ten days be cool enough so the bees cannot fly.

We are now working on the scheme of uniting the weak colonies from two different yards. During the early part of September, in our locality, it is not practicable for us to unite the bees in one yard, on account of the bees returning; but when several half-strength colonies of one yard are united to an equal number at another yard the union is accomplished without any bees deserting and returning to their old stands. This early uniting results in a perfectly normal colony later on. But the objection, of course, to uniting bees from two different yards is the expense of hauling; but if one has to go to an outyard anyway, he can just as well take along a load of bees, and put them with other weak stocks in a yard where he expects to work.

What is a Trademark?

SOME centuries ago a medieval paper-maker conceived the idea of distinguishing his product from that of others by pressing a die into the paper and making the fabric thinner and therefore translucent in the form of the design. Manufacturers of other wares adopted the idea.

The quality of merchandise is due as much to the invention of the trademark as the efficiency of machinery is due to the invention of interchangeable parts, a development hardly more than a century old. The trademark indicates the pride of the manufacturer in his product. The confidence of the buyer must follow. Great systems of business, vast selling campaigns, the whole mass of modern advertising, would not be possible without the trademark.

It is not necessary to argue the value of the trademark for honey-producers. It is

a sales necessity for large success in everything from cruisers to collar-button. You may develop a trademark that may be your greatest asset. The name Coca-Cola is worth more than five million dollars.

There are certain things one must keep in mind in selecting a trademark or trade-name. His own name cannot be protected by use of any one else of the same name in marketing the same product. There are two firms making Baker's chocolate, two manufacturing Faber's pencils, two manufacturing Waterman fountain pens.

For the same reason it is impossible to prevent any one from using the name of a town or city or any other geographical name as the designation of a product. Any other honey-producer in your locality could build his trade on what you have worked up, simply by adopting the name of the locality if you were using it already. The same is true of words which are simply descriptive of the product.

Of course a trademark is valueless if the product is mediocre. If inferior the mark had better be dropped altogether.

In the case of marks such as the government has declared protectable, it is not necessary to register them to prove priority of use, although registry, of course, makes the mark more secure. If you have adopted for your product a sunbonnet girl or an apple-blossom or a coined word which no one else has used for a product of the same class, you may rest confident that no one can use the sign to attract trade that should be yours.

Another Visit from a Norwegian Bee-keeper who Uses American Methods

On page 668 of our issue for Oct. 1, 1913, we gave an account of a brief visit that we had had from Mr. Ewald Omdahl, of Drammen, Norway, a prominent manufacturer of leather goods, who has quite an extensive bee business as a side line. Mr. Omdahl has recently made another trip to this country; and while on his way from San Francisco to visit the exposition, on Sept. 2, he called again at "The Home of the Honeybee."

Mr. Omdahl says that there has been practically no honey produced in Norway this season, on account of the rain and cold weather. The conditions have been so bad, in fact, that there is practically no honey on the market.

There is much clover around Drammen—white, alsike, and red clover, the clover being the principal source of light honey. In addition to many other plants

such as are common in northern United States they have considerable heather. In commenting on the thick heather honey Mr. Omdahl says that they now have no difficulty in extracting it. A roller-like tool of German manufacture, containing a large number of sharp points, or needles, is run rapidly over the combs, the points reaching nearly to the midrib. As we understand it, this is done after uncapping. The thick waxy honey, which is almost impossible to extract under ordinary circumstances, may then be extracted with ease. Possibly some air is thereby introduced into the honey, which makes it leave the cells more easily. According to our Norwegian friend, even honey which has started to granulate may be quickly thrown out when this tool is used.

As reported in the former editorial, Mr. Omdahl uses both Carniolan and Italian queens. He has been buying rather more Italians of late, securing them direct from an extensive breeder in northern Italy. This is a very easy way to get imported Italian stock, as the queens reach him in just three days' time.

He told of a peculiar instance which occurred recently. He received a shipment of thirty queens, twenty-five of which were leather-colored; and the other five, goldens. All were fine-looking queens, but for some reason or other the eggs of the five golden queens would not hatch—all of the other queens being normal in every way. Occasionally we run across a queen whose eggs do not hatch, but have merely supposed such a queen to be structurally deficient in some way. We could not offer any reason why the eggs of all five queens should have failed to hatch. We suggested that the fact that the queens were goldens could hardly have anything to do with the matter; but Mr. Omdahl says that the general opinion of the beekeepers in his vicinity who use both the golden and leather-colored Italians imported direct from Italy is that the leather-colored are far superior.

Since the war broke out, European mail, of course, has been extremely slow. Under normal conditions it takes only three or four days for mail between Norway and Italy. Under present conditions all mail is "censored," with a resulting delay of a week or more. Importations of queens, therefore, are out of the question.

Mr. Omdahl believes more and more in providing an abundance of sugar syrup in the fall. He says there is no danger in giving too much, for extra combs of stores in the spring always come handy for weak colonies, and, of course, they are much to be

preferred over spring feeding. The fall is certainly the time to feed in the spring.

Successful Shipments of Bees in Pound Packages from Alabama to Canada

MR. W. D. ACHORD, of Fitzpatrick, Ala., called on us recently. Mr. Achord is a prominent queen-breeder and extensive beekeeper, owning from 500 to 600 colonies which he operates for bees, queens, and honey. Early this spring he sent something like 1000 lbs. of bees by express in various shipments to beekeepers in Canada, with a loss not exceeding two per cent. He began to deliver queens by April 1. Shortly after this his bees were swarming out, and, of course, his hives were boiling over with bees. There is not much honey in sight, and he can, therefore, fill orders for pound packages very easily. In fact, he finds it an advantage to take off the surplusage of bees; and after having done this they are in splendid condition by June 1 to catch the heaviest flow of honey for the year. In this way Mr. Achord is enabled to do quite an extensive business in bees, queens, and honey. He is a good business man, and his stock is first-class. The sale of bees in pound packages is just so much velvet.

One of his customers having experienced a severe winter loss said that his pounds of bees did so well that he did not know but that it would be better for him to brimstone his bees in the fall, save the stores, and buy bees in pound packages from Mr. Achord. He says that a pound of fresh bees from the South is more than equivalent to any colony that has been wintered over whose bees are more or less old or worn out by the rigors of winter. Some of these pound packages have paid for themselves several times over in honey.

The Tri-state Field Meet at Hamilton, Illinois, Sept. 7 and 8

WE have just returned from attending a successful field-day meet, at Hamilton, Ill., and have only just room enough to squeeze in a brief notice. The representatives of some six or seven states were present, including such men as Dr. L. H. Pammel, botanist, of the Iowa State Agricultural College, Ames, Ia.; Frank C. Pellett, bee-inspector for Iowa; N. E. France, inspector for Wisconsin; A. L. Kildow, inspector for Illinois; Frank Coverdale, of sweet-clover fame, Iowa; Dr. E. F. Phillips, of the Department of Agriculture, Washington; and, of course, the Dadants.

A fuller report of this field meet will be given in our next issue.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

P. C. CHADWICK gives a plan for transferring, page 616, that sounds excellent, and I'm not sure I ever heard of it before. But he doesn't say what he does with the old combs that in three weeks would be filled with honey.

A. I. Root, I'm interested in your work with hand cultivator, p. 599. I'm having lots of fun cultivating my roses and gladioli with a wheel-hoe. And to think I've lived till now without ever knowing how much easier it was than a common hoe!

FOOLED again! When the cold and wet kept bees indoors I thought when bright days came again they might do a rushing business, since clover bloom was still abundant. Didn't work that way; and although clover is still booming, 1915 may as well be set down as a rather poor year. [The same in our locality. The clovers were out in bloom the 15th of August, but they do not yield honey now, the 23d.—Ep.]

I WANT to say amen to J. L. Byer's note of warning to beginners, p. 704, about the danger of letting bees run short on stores early in the season. If it goes to the point of having the bees destroy brood, the ruinous results are far beyond what one would estimate. I had one case this year, and the colony was many weeks recovering. In fact, it was practically ruined as a honey-storer. It would have paid well to feed at a dollar a pound.

P. C. CHADWICK thinks it a bad thing to have in spring two to four brood and pollen each side, p. 525. I've often wondered about that. But I haven't dared to interfere with it, for that's the regular thing; and when the bees make a rule to do a certain way, isn't there some good reason for it? A common thing is to find pollen on the inside of a comb and young brood outside; and then in an incredibly short time the pollen disappears. May be that's the best—possibly like having dinner all on the table instead of upstairs or down cellar.

ALLEN LATHAM writes: "Foul brood has been very bad here this year, and the caging of the queen has failed in many instances. I think that will work only when new honey is coming in. All colonies are getting cured, now that the honey-flow is in progress." I suppose he means European foul brood. A flow is very helpful in treatment—even a cure in some mild cases;

but I think I've had caging a success in a dearth. [European foul brood is undoubtedly meant; for Mr. Latham is not a beekeeper who would claim that caging would cure American foul brood. This only illustrates the importance of specifying which type of foul brood is meant. Will our correspondents please be specific?]

ONE OF the hardest things I've had to learn (I'm still learning it) is that everything about beekeeping all over the world isn't exactly the same as right here at Marengo, Ill. In a British Columbia bulletin written by our wide-awake friend F. Dundas Todd, he says British Columbia differs from almost the whole world in having a spring-building-up season *four months long*. Clover begins to bloom in May, but apparently nectar is not secreted *until June is past*. So with plans that fitted in Ontario, beekeeping was a flat failure; with different plans, fine yields are obtained. [If you traveled all over the country as much as we do, from one end to the other, from the extreme east to the extreme west, and from the extreme south to the extreme north, you would have it pounded into you pretty thoroughly that there is a very marked difference in localities, and that locality explains differences when one knows the exact conditions. Many of those who criticize the late E. W. Alexander's methods would be less inclined to do so if they knew the conditions surrounding his locality.—Ep.]

J. L. BYER, you have my hearty thanks for entering a protest, p. 617, against the thing that so constantly vexes my soul, the talking about foul brood without saying whether it's American or European. I have my opinion of any editor who will allow anything of that kind to get into print. [If you were an editor you would, perhaps, realize better than you now do the futility of trying to make every correspondent make a direct distinction between the two kinds of diseases. We admit that, as the modes of treatment are different, it is very important to know what the writer is talking about. We should appreciate it if all our old correspondents, at least, would be careful to prefix the proper adjective, "American" or "European," when they speak of foul brood.—Ep.]

GOT all kinds of foul brood now. After hovering about within 12 miles the past three or four years, American foul brood has finally concluded to pay me a visit.

Don't know what treatment I may use later; but as a starter I've adopted the carbon-disulfide-furnace treatment — carbon-disulfide for the bees, and then the furnace for bees and combs. [While we are awfully sorry for you, yet we cannot repress a feeling of satisfaction that what will be your loss will be a gain, perhaps, to the fraternity at large. We believe that beekeepers have profited greatly by your experience with European foul brood. While your plan for European will not work in all cases and in all localities and with all strains of bees, it will work in a good many cases. After all, is not this the basis of the Alexander treatment?—Ed.]

"FAMILIARITY breeds contempt." I suppose it's according to that old adage that R. F. Holtermann, p. 707, thinks American, and I think European foul brood the lesser of the two evils. With his vigorous treatment I don't believe he'll have much trouble with European foul brood. At present I don't believe I dread European foul brood any more than I dreaded wax-moth with black bees. R. F. rather belittles the damage from destroying combs; but I've found that shaking means the loss of half to the whole of the surplus for that season, while with European foul brood the caging of the queen for ten days makes little impression on the harvest. And taken in time that caging is all that's ever needed. But we'll know more about it a year from now, Bro. Holtermann. [We should like to get reports from our subscribers who have tried this ten-day caging plan of Dr. Miller's for the treatment of European foul brood. While you are about it, do not get the plan mixed up with the American disease, for it will not work.—Ed.]

MR. EDITOR, you ask, p. 701, my opinion of the Fowls plan of swarm control. Please understand that my quarrel with Miss Iona, April 15, p. 261, was not at all about the value of the Fowls plan, but because she said "putting the queenless colony right on top with nothing but the honey-board between . . . the chances are that the swarming tendency would very rapidly develop into a mania," for I had done that very thing many a time, at all stages of the swarming fever, up to sealed cells, and even after the colony had swarmed, and it always cured the fever instead of developing a mania. What's that? "Want me to stick to the point and say what I think of the Fowls plan?" Well, it's excellent. Splendid! I'm not sure about that philosophy about the young bees, but it's quite possible that there is an advantage in having those intervening empty supers; for without them

I've known the queen to sulk several days before laying, and it may be that with the Fowls plan she goes promptly to work. If no increase is desired, all that's needed is to kill cells again in 8 days. Yes, it's a good plan, and I'd give \$49.98 (marked down from \$50.00) if I could use it. But it won't do for comb honey. [The Fowls are good beekeepers; and while we will admit that they do not know as much about the production of comb honey, the difference in their experiences is probably accounted for by locality as well as by the kind of honey produced. The attention of Mr. or Miss Fowls is hereby directed to what Dr. Miller says.—Ed.]

No matter how dry a cellar or refrigerator may be, says ye editor, p. 698, the tendency to granulate is hastened materially, meaning, of course, hastened by the cold. Very true; but isn't there such a thing as honey without a tendency to granulate? At any rate, I want to register my belief that comb honey properly ripened will not granulate with cold. That belief is based on seeing honey that had been roasted in an attic through the summer remain uninjured by freezing the next winter. [Practically all honey, both comb and extracted, no matter what treatment it may have had previously, will granulate if given time enough and subjected to alternate cold and warmth. Comb honey that has stood in a warm or hot attic for six months, if well ripened at the time it was taken off, probably would not granulate for a year if exposed to continuous cold; but it will be almost sure to do so the second year, especially if the temperature rises and falls.

A very thick and well-ripened comb honey would not be injured by freezing, because the water content is very small comparatively.

But look 'e here, doctor; you do not cover the point directly as to whether comb honey or extracted honey should be kept in a cold or hot place *continuously*. We assume, of course, that you are in line with the orthodox teaching on this point, although you did not say so in our last issue, and now you are silent again. You would not recommend putting a well-ripened thick or attic-stored comb honey into a refrigerator or ice-box and *keep it there* as a matter of good practice. Would you not rather keep honey in a warm dry place, and then store it in a refrigerator, or before an open window in winter time, for a few hours before eating? This last point has never before been emphasized so far as we can remember, and perhaps our old orthodox teaching should be modified slightly.—Ed.]

MR. EDITOR, you ask, p. 657, whether I think it advisable to have "one large brood-chamber or a multiple of two or more of medium size, and tier up in order to get the necessary capacity." Too many angles to that question to handle it in a single paragraph. If Langstroth frames are used in both cases, 14 or more being used, then I'd rather tier up for comb honey, the other way giving too large surface for sections; but for extracted honey—I don't know. A question involved is: "Which would suit the queen best?" I formerly thought she would dislike to cross the wood of the top-bar and bottom-bar, and especially the space of air between; but having tried it many times I find she keeps the work going in two stories just as well as in one.

On page 655 I say that the chief part of cleaning sections is done with No. 2 sandpaper. I've just watched Miss Wilson at work, and will now describe the work more minutely. Tops and bottoms are cleaned as I said, but No. 2½ sandpaper does as well as No. 2. For the rest of the work No. 3 is used, making better work. The sandpaper lies flat and on this she lays the section flat, and with a few motions cleans the edges, then reverses the section and cleans the other edges. Then she lays the section on one of its sides, gives it a few rubs, turns it over on its top, rubs; turns it over on the other side, rubs, and it's done. I said I didn't see much use in rubbing the top, which was already clean. She replied, "Sometimes there's a little to clean on the corners, but the chief reason for having the top down is because it's easier to roll the section over in that way than it is to pick it up and lay it down on the other side." If there's much glue on the edges, and it's pretty warm, then the knife precedes the sandpaper. By the way, since testing that knife you sent, in actual work, she says it's fine. [Apparently there are times when the knife is better than sandpaper. It would seem to us that both methods should be employed, according to the condition of the atmosphere, propolis, or the sections themselves.—ED.]

YE EDITOR asks, p. 657, what I mean by "breeding from the best." My first thought was, "What a fool question!" But after studying over it a bit, I conclude the foolishness is elsewhere, and am strongly inclined to answer, "I don't know." The best for one is not the best for another. If I kept a few bees in town just for the fun of it I'd breed for gentleness, even if I didn't get ten pounds of honey per colony. If I wanted to sell bees or queens, color would be an important matter. But if I

bred bees for the honey I could get, then the bees that stored the most pounds would be the ones to breed from. Not altogether that, either. For years I paid no attention to anything else, and I had bees that would get the honey; but I also had bees that disputed my right to be on the same 37 acres with them. So I'd rather have a little less honey with less danger from stings. But I'm not sure I'd take anything else into account. Wintering, for instance, may be ignored. The colony that gets the most honey has wintered well enough. So the "best" would be those giving most honey, provided not too cross. For I'm afraid Vernon Burt is right, that if you want big yields you must take some temper with them. [Thanks, you have given us just the information we desire.—ED.]

You say, Mr. Editor, p. 613, "If you were in an office where four or five dozen queens were lying on a desk . . . you would hear a good deal of piping. We have heard them answer back and forth time and time again." So have I heard them piping many a time outside a hive, and, of course, outside a cell. But in answering back and forth were some of the queens *quahking*? Were they not all piping? I never heard a queen *quahk*, as I said, outside a cell; nor did I ever hear one pipe inside a cell. Did you? [It all depends on what we mean by piping and *quahking*. In your previous *Straw* you mentioned the fact that there are some who think they are one and the same thing. We are coming more and more to that opinion ourselves. If we were to shut you up in a cracker-barrel and have you call loudly you would *quahk*. Out of the barrel you would *pipe*. If you were to be shut up in that barrel for some time your holler might be prolonged in order to attract attention because the sound would be muffled. Of course, we realize the fact that barrels and queen-cells are not quite analogous because they are made of different materials. One might make a better sounding-board than the other.]

After all, doctor, have you any proof that there is any difference in the *way* the sounds are made beyond the mere matter of environment? Now, then, to answer your question, if they are made in the same way, we have heard queens pipe and *quahk*, both inside and outside of a cell and inside and outside of a hive. Inside of the cells the sound might properly be called *quahking* because it is muffled; and outside, piping; but we strongly suspect the sounds are made with precisely the same organs and in precisely the same way. If so, why draw a useless distinction?—ED.]

J. E. Crane

SIFTINGS

Middlebury, Vt.

We tried this year a small strip of foundation on the bottom of sections as recommended by Dr. Miller, but do not find such sections any better attached at the bottom than those in which we used a full sheet coming down to $\frac{1}{4}$ inch of the bottom of the section.

* * *

Passing a field of alfalfa in full bloom yesterday, Aug. 16, on my way to an out-yard, I had the curiosity to see if bees work on the flowers, and found them in goodly numbers. I presume they have not learned that alfalfa doesn't yield honey east of the Mississippi River.

* * *

That photogravure showing how bees are kept in the Blue Ridge Mountains, page 533, July 1, by J. J. Wilder, is very enlightening. How little some of us know the way many people live in other sections of the country! and we may well be grateful for the enterprise of our journalists for the knowledge we do have.

* * *

Mr. Conover's method of fastening foundation into sections would seem to make a good deal of work without corresponding advantages as given on page 585, July 15. Now, after many years' experience I believe that where honey is coming in very fast a small amount of foundation can be used with satisfaction; but where it comes slowly a full sheet of foundation is most economical.

* * *

Quinby tells us in his book that clover will sometimes continue to bloom all summer and yield honey. Such a season was 1865, as I remember. I have been looking for another for the past fifty years, and it has come at last; and now, Aug. 12, clover is yielding honey as fast as on July 1. Alsike is still as fresh as it usually is the last of June, and bees are working, when the weather will permit, as fast as at any time through the season.

* * *

In a paragraph on page 570, July 15, I referred to the certainty of bees being poisoned by the spraying of fruit-trees. Thinking it might throw some light on the question, when I found how badly they had been poisoned I gathered up a handful of dead bees in front of one hive, perhaps half a pint, and sent them to Dr. Phillips to be analyzed at the Department of Agriculture.

His report shows an abundance of arsenic found in the dead bees. Pretty conclusive proof! I have since learned who did the spraying, and that they used arsenate of lead. It remains to call the parties to account for it, and settle for damages, as the spraying was illegal.

* * *

That article on pages 574 and 575, July 15, by Chalon Fowls, is of unusual interest. Why shaken swarms should swarm out has given me a good deal of thought and study. I have not laid it so much to too many young bees as to other causes. Natural swarms often take with them almost every bee in the hive that can fly. My own failures have come largely from shaking colonies with old queens (two years or older), or by delaying the shaking until the bees were nearly or quite ready to swarm. By shaking only colonies having vigorous queens, and those as soon as we find larvæ in queen-cells, we have little trouble from their absconding. Old or inferior queens should be destroyed when they prepare to swarm, if you can find them; and after destroying queen-cells give a choice virgin queen or a queen-cell. These swarms made by shaking have proved my best workers. Shaking on to frames of foundation is often a cause of absconding, and natural swarms are no exception.

* * *

"It is a brave man that dares to stand before the king," or stand up and disagree with our friend R. F. Holtermann when he tells "how not to do and how to do." I shall not quarrel with him for thinking that the way he describes on page 490, June 15, is best for him to handle combs, and perhaps many others; but there may be some beekeepers, and myself among the number, who would find such a way decidedly irksome. I find I can work when the brood-chamber is high enough with the least weariness by standing; but if the brood-box is low I can work best by kneeling on the ground or a cushion of shavings. It is my opinion that beekeepers as well as other people are built differently. One may be tall and another short. One may have a large development of muscles in the arms; another in the shoulders, and another in the lower part of body or legs. Now let every one find out for himself how he can work easiest and most rapidly, and stick to it until it becomes second or third nature to him.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas.

A NOVEL AND PROFITABLE WAY TO
SELL HONEY.

While at the recent meeting of the State Beekeepers' Association at College Station we learned of a unique way of disposing of large quantities of honey profitably. The plan was used successfully by Mr. J. H. Meeks, of Nederland, Texas. He had a large quantity of honey to sell. It was somewhat difficult for him to sell it direct to the merchants for them to sell again to their customers. They believed there would be few if any calls for honey, and consequently they were afraid to stock up with a supply.

Mr. Meeks' plan was like this: He obtained permission of the merchants to leave at each store in town a supply of honey without obligating the merchants to pay for any of it unless it was sold by them. Then he went to the newspapers and placed in the classified "want ad." columns such advertisements as, "Eat Meeks' Honey. To be had at all groceries." "Meeks' Fresh Honey. Call at your grocer's." Other similar, short, catchy advertisements were used. These were placed in nearly all the columns, scattered under the heads of "Help Wanted," "Live Stock," "Type-writer Supplies," "Poultry and Pet Stock," and almost all the other captions. The result was good, for a demand was created for this honey, and the merchants sold honey when they had believed they could not get rid of it. Mr. Meeks worked this scheme in a series of towns that could be reached by the same newspapers.

THE FOUL-BROOD WORK IN TEXAS.

Thirteen thousand dollars was appropriated by the last legislature of Texas for foul-brood eradication—a larger sum, we believe, than has ever been appropriated for this purpose at any one time. Three thousand dollars of this amount was an emergency appropriation for the rest of this fiscal year ending Sept. 1, as there had not been made any appropriation for the last two fiscal years. There was no money with which to look after the work, and consequently it became necessary to get some money with which to resume the abandoned inspection work. Five thousand dollars each year for the next two fiscal years was allowed in the regular appropriations for the State Experiment Station. This will give us sufficient money to do some effective

work. It is to be hoped that it will be spent advantageously, and efficiently applied, and that the work will result in cradicating the disease to such an extent, at least during the next two years, that there need be less fear from its ravages than now exists.

We are only hoping that those in charge of the work will give it their proper attention. We know it is quite a difficult task to take care of as large an undertaking properly, involved with so large an appropriation. With the right man at the helm it will be less difficult, and it is our fondest hope that the Texas Experiment Station will obtain a man who will be well qualified to handle ably the funds for this purpose.

It is my opinion that the beekeepers should themselves take a bigger interest in this work and in the spending of this money. It was appropriated for them and their cause, and they ought to see to it that they receive "their money's worth" out of it. As a member of the legislature myself, as well as one of the beekeepers, I feel that I understand the situation somewhat better than the average person. I should like to urge a stronger co-operation among the beekeepers of this state in foul-brood inspection and eradication work. The beekeepers can be of very material aid in more efficient work being done with the money appropriated for their cause. With the beekeepers working hand in hand with the State Entomologist at College Station, greater good may be obtained. A united effort of all concerned will mean more than a haphazard, go-lucky manner of procedure. Let us hope that every beekeeper, whether his bees are diseased or not, will take an earnest interest in this work. Get in correspondence with the State Entomologist, at the above address, who has charge of the funds and the foul-brood work of Texas. We have the chance of a lifetime to do some good work with the generous appropriation now at hand, and it is my keenest desire to see the funds well spent. I should regret to have to appear in the legislative sessions hereafter and have my colleagues, who so kindly aided us in getting the money, call my attention to the fact that the money was not well used. I am not anticipating this, and feel that the beekeepers and the State Entomologist will work for a united effort toward stamping out the dread disease that is a menace to our industry.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

SPREADING BROOD; PIPING QUEENS.

"Did you read what Editor Root said on page 345, May 1, about the folly of spreading brood? Again, did you read Dr. Miller, p. 435, June 1, on the same subject? I am surprised at what both write.

I have spread brood with good results for more than twenty years, in accord with what you told us at a National bee convention which I attended nearly a quarter of a century ago. Do you still practice spreading the brood?"

Since I began using the plan of "millions of honey at our house," as given in the "Management of Out-apiaries," I have not been as enthusiastic about spreading the brood as I was twenty-five years ago—not that a gain cannot be made by a judicious spreading of the brood, but the work and manipulation, as well as a careful diagnosis of each colony, overbalances the extra gain that can be made above the abundance-of-honey plan as hinted at by Dr. Miller.

But both Editor Root and Dr. Miller put two words in what they wrote that would make the spreading of brood a failure nine seasons out of ten; and to me it is no wonder that Dr. Miller says, "In my locality, and with my bees, brood can be spread in spring always and only at a loss." The two words are "empty comb." Empty combs put between combs of brood are no incentive toward a greater laying of the queen unless there is an abundant flow of nectar to be had from the fields, and such a flow is not the rule at the most advantageous time for spreading, which time is always from 35 to 40 days before the main honey crop will be at its best. Putting an empty comb between combs of brood at a time when the bees were living "from hand to mouth" would be like throwing a wet blanket over a lot of motherless chickens on a cold morning, resulting, as Editor Root tells us, "in almost irreparable damage to the colony should a cold spell come on." Any comb that is to be put between combs of brood should be full of honey, and that honey preferably sealed, though in the absence of honey a comb filled with good sugar sirup of the consistency of honey will work nearly as well. If the sealed honey is partially candied it will do no harm, especially if a cool spell of several days should come on. The cappings to the cells should mostly be broken by passing a knife flatwise over them before the comb is

inserted between the frames of brood. By thus spreading you will cause a great activity to come to this colony, the queen to be abundantly fed by the bees, and the necessary heat kept up during quite a spell of cool weather, while the honey not consumed in brood-rearing will be stored all about the brood, the same as would be the case with a day's flow of nectar from the fields during a time of scarcity, making quite a gain in bees at a time when such bees would work to the best advantage in the main honey harvest.

"I see that you are behind the times as to the piping of queens except when they are on the combs in the brood-chamber, p. 312, April 15. Have you ever heard queens piping in cages with bees where they were to be sent in the mails or otherwise?"

Certainly, a great many times. As the questioner was a person whom I had instructed to listen at the side of the hive for the piping of queens so that he could locate the time of day when an after-swarm could be expected (this piping matter being entirely new to him), I answered from his standpoint, not for older heads like E. R. Root, Dr. Miller, J. L. Byer, etc. Where there are only scores of these old veterans (in the commercial handling of queens) who are readers of GLEANINGS, there are hundreds who know little regarding queens only as they are inside of the hive, except that they accompany swarms which issue. When I wrote what I did I was writing from the standpoint taken by the multitudes who had kept bees for only a few years, or had from three to fifty colonies.

Again, it will be noticed that I was talking about young or *virgin* queens. Now allow me to propound a question for these "older heads" to answer. Did any of them ever hear a *virgin* queen pipe or quahk at or in any other place than the combs of the hive where there was rivalry among these queens? If they have, then I am "behind the times," as our questioner says. I have sent out scores of virgin queens in the mails, but I never yet heard any virgin queen pipe in the cage nor in any other place, except on the combs where there were rival queens in queen-cells. In my writings I have always tried to give something useful to the great mass of everyday beekeepers, and something which they could reasonably put in practice with the means they had, without going to some great expense to secure something they did not have.

GENERAL CORRESPONDENCE

DIFFERENT VIEWS OF FOUL-BROOD DON'TS

BY G. C. GREINER

In a former number of GLEANINGS a beekeeper from the West gives a list of "Don'ts" which he considers a safeguard against foul brood. Some of his points are all right, but others I cannot endorse without some remonstrance. The limited space of an article of this kind forbids replying in detail to the different features his 'don'ts' cover, although it would give me great pleasure to do so.

Our friend advises "burning all diseased hives unless there is a large percentage of the apiary infected." Why does he make this difference in the number of hives infected? If it is advisable or necessary to burn a few, would it not be more so when a large portion of the apiary is in the same condition? It may be the least trouble, causing the owner less work to commit his hives to the consuming flames than spending time in cleaning them up; but it is also the most wasteful. From experience I know that infected hives can be easily prepared for future use without the least danger of detrimental consequences.

A day or two after I had finished treating my last foul-broody colonies four years ago,* our foul-brood inspector called on me in his inspecting-tour; and while looking over the rows of hives with their rotten contents our discussion naturally turned to the question of what best to do with the rotten mess. Of course I had decided to burn all the contents of the hives, but felt somewhat undecided about the hives. It seemed like a pitiful waste to see the work of former years so ruthlessly annihilated, to say nothing of the material, unless it was strictly necessary. Here is where Mr. Stephen, the inspector, came to the rescue. He suggested two methods—either scorch the inside of the hives with a gasoline torch or thoroughly scrape and liberally paint with kerosene. I decided on the latter treatment, because the scraping alone would make them mechanically as good as new.

One evening, after all danger from flying bees had passed, I burned the frames and combs; and to make a clean sweep I moved the hives into my carpenter shop where I securely closed them up against all possible access of robbers. During the winter I did the disinfecting. After scraping every

particle of inside surface thoroughly I gave them a soaking coat of kerosene, using a large flat brush for this purpose, which made them practically as good as new. I use these very hives to-day.

LETTING BEES CLEAN OUT EXTRACTING-COMBS.

Then our western friend advises not to set out extracting-combs for robbers to clean up. It may not be strictly necessary to let bees clean out extracting-combs before storing them for winter, but it is preferable. The honey remaining in the combs after the last extracting will granulate; and when mixed with the next crop it will hasten its granulation. During the early part of the season bees will clean out this granulated honey before storing the new; but when honey comes with a rush they have not the time to do it. If our friend objects to letting bees clean extracting-combs on the ground that it is liable to spread the disease, I am inclined to think he is more scared than hurt. I have practiced the same plan for fifteen or twenty years, and see no reason why I should break off now. Of course, it must be done in the right way, and we must be sure that there is no disease in the yard.

The one-bee-passage plan, as advised by some of our most prominent beekeepers, does not engage bee nature to the best advantage. It defeats our object in more than one way. Instead of assisting our bees in the performance of a certain function we hamper them all we can. It only gives the stronger portion of the bees engaged the advantage over the weaker ones; and the latter, when driven away or crowded back, will try to enter some other hive, possibly a weak or queenless one, where their presence is not desired. Even if no vicious robbing is noticed, peaceable robbing, as we generally call it, is liable to be started. And this is not strange; for the beekeeper's own mismanagement has taught them the trick. The stinging inclination, which we always notice when bees are robbing, is caused in this way. Those bees that are crowded back are not so willing to give up. They know by scent and general disturbance that honey is being found; and, being excited and deprived of the privilege of partaking themselves, they vent their spite on anything they run across.

Besides teaching bees to fight, and fight

* We ascribe but our correspondent is talking about American foul brood.

The late afternoon is the best time to permit the bees to clean out extracting-combs.

at the most dangerous place, the hive-entrance, the small passage, is the cause of another very undesirable feature. It wears bees out unnecessarily. The constant rum-pus at the small opening, the rolling and tumbling, the pushing and crowding to gain admittance, exhausts the last remnants of vitality of the older stock, for it is mostly that class, the field workers, that suffer in these combats. After they have forced their way in and have loaded themselves it is the same scramble to get out. At best it is a cruel treatment we inflict upon our bees. Some of our experienced beekeepers advocate this plan, and call it the proper way.

As a comparison I refer the reader to the accompanying illustration. It represents a few stacks of extracting-combs and bait-sections ready for the cleaning-out by the bees. At the proper time, which I will explain below, all the covers at the top are removed. Previous to this no bees are allowed to enter the stocks, and special attention is paid to the closing of the hive-entrances. In a very short time, after the stacks are opened, all the bees of the yard seem to be on the job. As they can go in and out uninterruptedly, there is no crowding or fighting, no stinging or wearing themselves out. Bees have free access anywhere; and from all appearance they act almost as natural and unconcerned as when gathering honey from the field during a honey-flow. There is not the least danger of being attacked when walking through the midst of them, as is frequently done when this operation is under way. It is needless to say that it does not teach them

to look for mischief at the hive-entrance which is one of the objectionable features of the one-bee-passage plan.

Selecting the proper time of opening the supers, referred to above, is the only part of the program that needs a little more explanation. About 3 o'clock in the afternoon on a warm, pleasant day, when bees are flying freely, and when there is no prospect of a chilly night to follow, is the time to give best satisfaction—first, because bees have sufficient time before nightfall to finish their job. Incredible as it may seem, I know from experience that any number of colonies, large or small, will clean out the supers they have used during the season in less than two hours if conditions are favorable. But it must be remembered that I extract direct from the hives. If honey has been removed for days or weeks before being extracted, it may take longer.

Second, in case of an absolute honey-dearth, when bees are more or less aroused, which the exposure of honey will always cause at such times, the oncoming night will quiet them again before they have time to plan another raid.

Third, being so nearly time for bees to quiet down for the night, neighboring bees are not so liable to be attracted by the exposed honey.

Some beekeepers do not favor the open exposure of honey, because the strongest colonies, that need it the least, are apt to get the biggest share. This is true. But it is too small a matter to take into consideration. All the honey bees can carry away in the short time of an hour or two would

not increase the supply of a colony to any great extent, even if arrangements were made to give one colony the exclusive cleaning-up of five or six supers. But to make this practical requires quite a little work.

If a colony is short of stores, a comb or two of capped honey added in the brood-chamber combines the least trouble with the best results.

BEE-DISEASE LEGISLATION IN NEW ZEALAND

Keeping Bees in Box Hives Illegal

BY W. B. BRAY

New Zealand beekeepers from the earliest days of commercial beekeeping have adopted American methods and appliances. Mr. Isaac Hopkins was the first to recognize the possibilities of the new methods, and the credit is due to him of having shaped a good course for others to follow. To him also is due the credit for the "efficiency apiaries act" which we possess. Already it has enabled us to make considerable headway in the battle against disease.

Though the bee-journals are concerned mainly with the commercial side of beekeeping, the readers now and again get glimpses of the go-as-you-please style of beekeeping which is generally associated with box hives. It is the farmer who keeps a few bees for his own use in box hives who is to blame for the continued spread of disease in the United States in spite of the efforts made to control it. Many of the states in the Union have an apiaries act on their statute-books, yet hardly any two acts are similar, and, in the opinion of New Zealand beekeepers, none of them are as efficient as ours which was passed in 1907.

From 1908 to 1910, as an inspector under the act, I had practical experience of its application; and I may say that provision is made for every condition likely to confront the inspector, and no one has yet driven the proverbial "coach and four" through it. Numbers of successful prosecutions have been instituted under the act, and in this respect I think our act stands alone.

The inspectors are permanently employed, there being four on the staff at present. This is much better than appointing beekeepers to do the work in their spare time. The inspector has the right to enter any place where bees are kept. In some states he can go only where disease is reported, so he has little chance of finding the source of infection. Under an amendment passed last year we expect regulations to be issued shortly to provide for compulsory annual registration of apiaries so the inspectors will have no difficulty in locating every hive.

In some of the states the inspector is hedged around with all sorts of restrictions due, I suppose, to the fact that he is not a permanent official. Our act specifies what the beekeeper must or must not do, and the inspector is there to see that the act is complied with. No compensation is paid for diseased colonies that have to be destroyed, and the inspector can use his discretion in condemning them.

But it is the clause that makes the use of the box hive illegal that has been the mainstay of the act. The box hive is the careless beekeeper's hive. The box-hive man never cares—in fact, he does not know—whether his bees are diseased or not. He is satisfied to get a little honey sometimes; but in taking it he may spread disease right and left. This class of beekeeper was all too common in New Zealand; and, while he was allowed to continue, it was hopeless to expect to control disease. He had no financial interest at stake, yet he imperiled the very existence of apiaries which cost hundreds of dollars to establish.

This clause has been firmly enforced, with the result that a good number have stopped keeping bees altogether, with no loss to themselves and to the benefit of the industry. Others transferred, but they continued their slipshod methods, thinking the frame hive was an automatic affair that required no attention. This class too generally decide to get rid of their bees when the inspector comes along and requires them to do certain work to cure the disease he may find. Then there were others who transferred and realized the advantages of frame hives. They have been only too ready to learn all they can about their bees, and are as anxious as anybody to fight foul brood. It is this class that is to-day swelling the ranks of the up-to-date beekeepers. The result now is that some districts are entirely free of foul brood, and in most of the best beekeeping areas the amount of disease is very small to what it was, and is rapidly diminishing. There are fewer beekeepers; but more and better bees and honey are

One hundred twenty-five colonies wintered almost without loss, at Sabetha, Kans. Many of these had a set of extracting combs, containing a very little honey, *under* the brood-chamber.

being produced by the ton where not even a hundred weight was formerly produced. The opposition to this great change has been infinitesimal.

It is difficult for a publication like *GLEANINGS* to advocate the compulsory use of frame hives without the cry of "self interest" being raised; but if the beekeep-

ers themselves study their own interests they should, at their meetings and conventions, give their approval to the principle that bees must be kept in hives which allow a thorough inspection to be made of the combs. Then with permanent inspectors on the job all the time they will get some value for the money expended on their behalf.

Wainin, N. Z.

COLONIES SUCCESSFULLY WINTERED OVER A SET OF EMPTY COMBS

BY FRANK HILL

I have a neighbor who last fall had eight colonies of bees. Last year was very dry and hot, and the honey crop was an entire failure. By my advice he fed all his colonies, but he did not feed all at once as I advised, but a quart or so at a time at intervals of four or five days. The sirup was made of granulated sugar two parts, and water one part. In making it, water was heated and the sugar stirred in after the can had been taken from the stove. The sirup was fed to the bees from a perforated can in a super, and in the latter part of September and first part of October he did not pack his bees very well, but they had a burlap cover over the frames with a good tight wood cover over that. With no more protection than this he has wintered for years; and always, before, his loss has been very small. All his bees died.

Another neighbor having had 18 colonies lost all but five. This man did not feed till very late; but his bees died the same way.

They seem to have died of dysentery as the frames and combs are daubed and are in a filthy condition.

My bees wintered splendidly, and only one colony died. At no time during the winter was there a longer time between flights than three weeks. We had two cold snaps, mercury going down to —13 once and —15 once. We had more snow than we ever had. My bees were fed in September from Miller feeders, the necessary amount being given at one time. As there was absolutely nothing coming in in the late summer and fall I also fed from outdoor feeders, for a month, thin sirup to get the queens laying to get young bees for the winter.

When the bees got strong a year ago last spring I put extracting-supers on all of them. The season was a failure, and there was not a super in the lot that had more than 4 or 5 lbs. of honey in it. As shown in the photograph I put some of these supers *under* the colonies. All the colonies

Danielson's 146 colonies in a 14 x 28 cellar, which wintered without loss.

have a four-inch tray with burlap bottom, filled with planer shavings over them. Over that I folded tar paper that comes well down the hives with the excelsior cover on top. Is it not an advantage to put a set of combs full depth under a colony of bees before the winter sets in, even if there is not a drop of honey in them? It seems to me as if they would be better protected from the cold winds, and they would not be as apt to come out on bright cold days. If there is any objection to this plan I should like to know it.

Sabetha, Kan.

[This plan has been tried before, but we do not recall any other definite report as to its value. We should suppose the entrances would have to be guarded by wire screen with mesh large enough to let the bees in and out, but small enough to keep the mice out—otherwise there would be danger that the mice would revel on the exposed combs and destroy many of them.

If any honey were left in the combs in the spring, would there not be danger of robbing?

If any of our readers have had any practical experience with the plan we should be glad to hear from them.—Ed.]

A SUCCESSFUL CONCRETE BEE-CELLAR

How a Low Temperature and Damp Atmosphere were Overcome

BY J. I. DANIELSON

I am sending you a flashlight picture of my bee-cellar that I built last October, which is 14 x 28 ft., with a building of the same dimensions. It is ventilated by a five-inch tile running 120 ft. from the cellar, in which the fresh air comes through and the damp foul air passes out through a trap-door in the floor above. But even with this ventilation the cellar has been a little damp.

I put 146 colonies in the cellar Dec. 10 and 11. There was snow on the hives which we could not sweep off, so it also went into the cellar with the bees. It soon melted, and caused some dampness.

The cellar-walls are made of cement,

which did not get thoroughly dried. There were large drops of water all over the wall and floor above.

The floor is of one-inch lumber which is not frost-proof by any means. It turned cold in a day or two, the thermometer registering 10 degrees below outside, and the temperature in the cellar was below the freezing-point. The walls and ceiling were covered with frost. I was thinking the cold weather would not last long; but it hung on for several days. The idea struck me, that sawdust would be a good thing to put on the floor to keep out the frost. So I got a load and spread it on about four inches

Polk County beekeepers' picnic, July 14, 1915, held at the apiary of N. J. Harris, Highland Park, Des Moines, Ia.

deep. That ended the frost on the ceiling, but the temperature was still too low, so I put a small stove in one corner of my cellar, letting a stovepipe through a window. This raised the temperature and dried out the cellar. The temperature then stood at 43 most of the winter. I did not use the stove after the dampness was removed.

The bees wintered in fine condition without the loss of a single colony. However, after removing them from the cellar I lost six. Three of these were queenless. Two

were robbed out, and the bees of one drifted, as it was a very windy day when I set them out.

I swept up one bushel of bees from the cellar floor. A few showed signs of dysentery. I do not think dampness is destructive to bees at a temperature of 45 degrees, with a good current of air. There was quite a bit of brood-rearing in all the colonies, so they were practically as strong when taken out as they were when put in the cellar.

Fairfield, Ia., April 23.

IOWA BEEKEEPERS' PICNIC

BY F. C. SCRANTON

There were about 65 in attendance at the picnic of the Polk County Beekeepers' Association.

Dr. Pammell and Prof. Bartholomew, both from Ames, and Mr. Pellett, state bee inspector, gave very instructive and interesting talks. The beekeepers were very fortunate in having these three men in attendance. Miss Vessie Clow entertained with a fine reading, as did also Arthur Wright. J. W. Schlenker, of Ankeny, gave a demonstration in shaking. C. E. Dustman, of Des Moines, had a fine lot of queen-cells in various stages. Mrs. Longworth, the vice-president, presided in the absence of John Schweer, the president.

Two things the Polk County Beekeepers' Association can be given credit for are, securing recognition of beekeepers' associa-

tions in the State Fair Premium List, and securing a deputy county inspector for Polk County. Just as soon as Inspector Pellett saw the need for the inspector in this vicinity he decided to appoint a man for the work.

The object of the association is the encouragement of good fellowship among the beekeepers, educating the public in the use of honey, thereby increasing the demand, co-operation, and betterment in all directions. Probably the hardest thing we will find to cope with will be the securing of better prices as there always seem to be a few beekeepers in every locality who will dispose of their crop at any figure they can secure of it; but we can accomplish a great deal by united and determined effort for betterment in this line.

Des Moines, Iowa.

Swenson's combination hive bottom, valuable for ventilating, and also for moving bees.

THE BEST BOTTOM-BOARD THAT I HAVE TRIED

BY ED. SWENSON

There has been so much written on different bottom-boards that I will describe the one I think fills the bill the best of any. This one can also be used as a feeder; but since I prefer the friction-top honey-pail described by J. L. Byer I will merely say that, by inserting a dripping-pan with a float in it, it makes a good feeder for certain times.

The bottom is very simple. It is made 4 inches deep, with the back nailed in solid; but the front piece is hinged so it can be let down and used as an alighting-board. This piece has two hive-hooks which hook on to the side pieces to hold it in place when raised.

There is no floor nailed in solid, but a board of $\frac{3}{8}$ -inch material with a rim around that slides in or out, which can be raised or lowered as occasion requires. This board is used in early fall, winter, and spring. In the winter it is lowered so as to give a deep clustering-space under the frames, which seems to be their choice when conditions permit. It is also impossible for the entrance to become clogged with dead bees, as the entrance is over 3 inches above the bottom.

In the spring it is again raised so as to make less room for the bees to keep warm; then when warm weather sets in this board is slipped out and a screen frame put in

place. Two two-inch pieces are nailed on the under side of this screen frame which hold it together; and they also raise it up off from the hive-stand so the air can circulate through the hive when the screen is in. This screen is tacked on to a rim which has two headless lath nails partly driven in on both sides, which slides in saw-kerfs cut into the side pieces for that purpose.

The front part of this screen can be lowered so as to form an incline; or if the bees are inclined to build comb below the frames the screen can be raised so there will be only a bee-space between the frame and the screen, when it will still serve its purpose as a ventilator. Or it can be lowered so as to give a three-inch space below for moving to and from out-apiaries, or in summer, as extra means for ventilation, which may be necessary to help prevent swarming.

The entrance-block I use is a four-inch piece $\frac{3}{8}$ inch thick with a V groove cut into it and a piece of screen tacked on one side. This also serves as an alighting-board. This is slipped in or out to regulate the size of the entrance; and by shoving it far enough the entrance can be entirely closed, which is very handy in moving bees. As we have the screen bottom we need not worry about the bees suffocating. The photograph shows clearly how it works.

Spring Valley, Minn.

THE DEMAND FOR HONEY, AND METHODS OF STIMULATING IT

BY SUSAN E. HOWARD

The demand for honey is increasing, and it is from all classes of people. I try to educate my customers by demonstrating and advertising that honey is not a luxury but a necessary and economical food.

My first venture was in disposing of a surplus crop which did not move to my satisfaction in my neighborhood. Unknown to my husband, who had belittled the possibilities, I sallied forth on a pleasant after-

With the help of the bees, these eight tons of squashes were grown on five-sixths of an acre between 115 fruit-trees and 600 currant bushes; 54 bushels of green peas were also harvested before the squash-vines were ready to spread.

noon with my sample of extracted honey and a supply of hand-whittled toothpicks for individual sampling. I purposely chose a section of the town where I was little known, so that my success or failure would be on the merit of the honey as sampled or on the method of presentation.

Success was beyond expectation, and I returned triumphant to relate my experience and plan a new campaign for the morrow.

Increased duties have taken me from this work which I enjoyed, and which I have found had a lasting result in that the local stores sought my honey as people demanded the "Howard Honey." Previous to my canvass the storekeepers were reluctant to stock my honey, saying they had but a "limited demand," etc. It seems a business law that a dealer will not stock an unknown commodity; but when a demand is created by the customers expressing a preference, the dealer, if progressive, will supply it. In the language of the pharmaceutical manufacturers, "I have detailed the doctors." This, as carried out by the manufacturers, is to have traveling men call upon the doctors and leave samples of their preparation and extol their virtue and possibilities.

It is a common experience to have strangers call at the door and ask for honey, stating that their doctor recommended it for a cough or other bronchial affection, and had suggested or recommended that he could get pure honey at the bee-camp.

Duplicate orders are a large factor in my business, and I always consider my first order as introductory, and mention to the transient customer that I will fill all repeat orders with the same quality of honey, and by parcel post if desired. My experience is that price is a secondary consideration if the honey is clear, packaged neatly, and securely sealed. Under these conditions repeat orders are assured.

The container I have adopted is the regular lightning glass jar which appeals to the housewife as of value after the contents are used.

If near a thoroughfare, place a sign in a conspicuous place announcing "pure honey for sale," and you may be sure of sale,

especially if colonies of bees are in evidence. It is no unusual sight to see two or more automobiles at my gate, as I live on a much-traveled highway, and much of my trade is from a distance.

Another way of creating or stimulating the demand is by the distribution of leaflets which give recipes for the use of honey in cooking and medicine. These may be procured with your name and address for a nominal sum.

Always label your honey as of first quality, also with directions for keeping it if not for immediate consumption.

If your motto is "Quality and Absolute Purity," you need not question your future sales, but can feel assured that success will reward your efforts.

THE VALUE OF BEES IN FERTILIZING SQUASH BLOSSOMS.

Replying to your inquiry as to the value of bees to my squash and small fruits, I would say they are of the utmost importance, and they have been a great factor in my success in growing squashes. The development of a small orchard and fruit-growing is secondary to my bee interests; and while the trees and bushes are growing, I utilize the land by planting catch crops and fertilizing or cover sowings. The eight tons of squash shown in the picture were grown on five-sixths of an acre, which also carried 115 two-year fruit-trees and 600 one-year currant bushes.

The squash followed a crop of 54 bushels of green peas, which were harvested before the squash were ready to spread.

As recorded in *Apiarian Bulletin* No. 8, Massachusetts Department Agriculture, it was no uncommon occurrence to note four to six bees in a squash-blossom at one time, happy and contented. I have also counted 28 bees within an hour in one squash-blossom. The squash crop was the banner one for this section, for the land occupied, and was in marked contrast with results at a distance from my apiary.

To people who realized in a measure the good work performed by the bee it was a revelation, and substantiated my oft-repeated statement, "bees as flower fertilizers first, and honey production an after-consideration."

Stoneham, Mass.

THE VALUE OF SEPARATORS IN COMB-HONEY PRODUCTION

BY G. W. JOICE

Allen Latham goes after the production of comb honey with separators rather roughly shod, July 1, 1915. Some of his

statements being so far from "truth for this locality," for fear that such an article coming from such a well-known apiarist

might cause many beginners to attempt something that they cannot succeed in doing, I write this article in defense of the use of fences or separators. In fact, I wish to give the readers of GLEANINGS both sides of the story. I beg permission to quote often from the article by Mr. Latham.

"Which system can be made to yield the better average results?" Beyond all doubt, the average beekeeper and all beginners will succeed best by using separators. In fact, 99 per cent of the honey-producers would not have sections, even enough to put on the market, unless they used fences. (I am using the words fence and separator to mean practically the same.)

One of the objections to the non-use of separators is the trouble in crating on account of bulging combs. I discarded the idea of getting along without separators on account of the trouble with bulging combs and varying weights of sections from the same super. I was using full sheets of foundation at the time, but they would bulge anyhow. I have had finished sections weigh anywhere from 8 to 27 oz. each (extremes, of course), while with separators I have had 80 per cent of my crop grade "Fancy" to "Extra Fancy," and weigh within one ounce of the same all the way through. I never could come anywhere near that without separators.

Mr. Latham blames bulging to the use of weak colonies for comb-honey production. Not it, friend Latham. The strongest colonies are often terrors at the bulging trade, even going to the extent of tearing out the foundation (full sheet) of the next section, and bulging right on through it. In regard to brace-combs, that is something that is a rare bird with me—perhaps one section in a hundred. Often that is traceable to the foundation coming loose and lopping over against the fence.

I fully endorse Mr. Latham's views on the carton question, excepting that I do not care to have the honey more than even with

the wood. Fancy comb will not stand half the pressure Mr. Latham would lead the reader to believe. I carton practically all my honey for the retail trade and think it money well spent.

Mr. Latham writes: "Arguments for the production of non-separated honey are more than two:

"(a) It is less labor to prepare supers.

"(b) It is less labor to care for the product.

"(c) Bees more readily enter the supers.

"(d) Swarming is greatly lessened.

"(e) Honey is of better quality.

"(f) More sections can be put in a super.

"(g) A bigger crop can be produced.

"(h) Better for business."

I concede *a* and *f* without debate. As to *b* I acknowledge there are no separators to bother with; but think of the odd weights and various contortionate shapes some of the sections present. I should prefer separators for the ease of caring for the product.

In regard to *c* it is true, but not to any great extent. Perhaps they enter slightly better, but there isn't a great amount of difference. In regard to *d* my experience is the opposite. On account of the combs being built so close in the super, thus shutting off ventilation, the bees swarm more readily when the supers are without separators. Note that the Danzenbaker fences are similar to the dummies used in the Aspinwall non-swarming hive.

Passing to *e*, I find that honey produced with fences is of the better quality. It ripens more readily, contains less wax, is whiter, more fragile, tastes better, and sells more readily on the market. If I were to go back to producing honey without fences or separators I should lose half my customers on account of excessive thickness of cappings and waxiness of comb.

Passing on to *g*, the crop may be a few pounds heavier (I cannot see how), but is

lacking in uniformity. You are giving ten points of quality to gain one point in quantity. Mr. Latham acknowledges uniformity when he makes the following statement: "The casual observer will not note the slight difference in the sections of a fancy lot of separated honey * * ."

In regard to the challenge, I cannot see that it would have anything to do with the matter. No doubt Mr. Latham could select a nice even super of sections from his apiary, and the editor do likewise. But

carry the matter out among the amateur class. Compare the entire crop of the amateur (he may follow any instructions that Mr. Latham might write) not using separators, with that of a like amateur using separators.

Edon, Ohio.

[Mr. Latham has just sent us another very interesting article and several photographs which we shall probably reproduce in our Oct. 15th issue.—Ed.]

ADAPTING EIGHT-FRAME SUPERS TO TEN-FRAME HIVES

BY J. SAMUEL COX

It is almost impossible to do successful beekeeping with eight-frame hives, owing to the persistent swarming as soon as there is nectar in the field. All the hives of my first apiary being of this size, I had a great deal of swarming to encounter; but running for increase I was able to overcome in a great measure, taking all the first swarms and exchanging the old brood-nests for increase, in this way doing away with after-swarms.

When I could no longer use these brood-nests for increase, then came the trouble; for as soon as they were full of brood they again started to swarm. I was obliged to put all the brood on top of one super and give foundation below; for when I used drawn-out combs the bees were sure to fill them with honey before the queens could put enough eggs in them.

This interchange of combs soon gave me more drawn-out ones than I could find use for. Having a good stock of these eight-frame hives, bottoms, covers, and honey-boards, it was not possible to discard them. How to use them successfully, avoiding excessive swarms, surplus combs, etc., and get a fair honey crop, was a problem I had to face, the outcome of which is the accompanying picture.

All the brood-nests are now in ten-frame hives, while all supers are still the eight-frame bodies with eight-frame honey-boards and covers.

Having my ten-frame brood-chamber in its proper position all ready for supering, I take a piece of board previously prepared, the full length of the hive, $3\frac{1}{4}$ inches wide, $\frac{7}{8}$ inch thick on one side and $\frac{1}{4}$ on the other; putting on the wood-bound honey-board, I allow it to hang over $\frac{1}{4}$ inch on one side, when this above-named prepared piece is put on the other side that the honey-board does not cover. I then take an eight-frame hive with one of its bottom edges rabbeted out lengthwise $\frac{1}{4}$ inch. Putting this on the honey-board I allow this rabbeted side to project over on the prepared piece so that the $\frac{1}{4}$ -inch groove fits snugly on it. This keeps it water-proof. Instead of making this bit of board $\frac{7}{8}$ thick on one side it can be made the same thickness as the honey-board rim against which it butts; but being $\frac{7}{8}$ thick it gives a better slant for the water to run off.

As will be seen in the picture, the two hives on the back stand have one of these pieces on each side while the super is in the middle.

Eight-frame supers on ten-frame brood-chambers.

This looks a little better as to its form, but gives nearly three times as much trouble to fix up as the one with only one piece; and consequently, for the man who has little time, I would say the one-piece is better.

It may not be out of place to say here that the small tree on the right-hand corner of the picture is a bay-tree, from which bay rum is made. It is the principal shade for this apiary.

Guayama, Porto Rico.

AN EXPERIENCE WITH A TOWN BEEKEEPER

BY RUTH C. GIFFORD

One morning I was sitting on the edge of our back porch nailing honey-cases together when Mr. K., from the little town of N., drove in. He stopped his horses with a jerk, looked at me very carefully, and then sputtered out, "Say! I got two colonies of bees up in my back yard you can have if you will take them out of there."

"What is the matter with them?" I asked.

"Well, the blamed things are cross, and I'm afraid of them. Last summer I took the honey from one, and those bees stung me through three pair of pants and two coats. My wife had my head tied up in a sun-bonnet with a lot of mosquito-netting wrapped around it: but the bees got under it, and I had a terrible time. At present they are so cross that they're even stinging to death my chickens and ducks. I wish you would take them away. You can have them for nothing if you get the honey in the top part for me. They are both good strong colonies that will make you a lot of honey. They are in home-made patent hives."

After thinking it over I told him I would take them. But I wondered at the time why he laid so much emphasis on the fact that they were in home-made patent hives. I had never seen any until I saw his, and then I understood very clearly.

As soon as the flow from buckwheat and second crop was well started I went over to take off the honey for him. With me I took my bee-suit, an extra bonnet, a good smoker, and plenty of saltpeter rags for smoker fuel. The extra bonnet was for Mr. K., who wanted to "help."

The bees were at the south side of the barn in the chicken-lot. They were so close to the gate that a woman's dress would brush against one of the hives every time she went to care for the chickens. The lot was fairly large for a town lot, and at the lower side of it was an open meadow. If he had kept his hives close to the fence on the lower side, instead of near the gate, his bees would not have bothered people who went in or out. They need not have annoyed anything in the meadow either, be-

cause he could have fastened burlap along the four-foot fence, and then had a thick grapevine above that. In the photograph, two sticks leaning against the building mark where the hives stood. The gate is just out of sight at the left. If he had placed the hives at the lower end of the barn, or at the sunny end of the small unused pigpen, which is next to the fence in the picture, he would have had less trouble.

A bad place for a colony of bees.

Then I started on those home-made hives. They had two-inch cleats around the outside at the top. The covers were of the gable telescope type, and exactly the same size as the hives, and so, of course, they rested on them and fitted snugly inside the cleats. The supers were a good bee-space smaller than the telescope covers. The bees found this space and just about filled it with propolis. Inside the supers two-inch-wide frames ran crosswise. The bottoms of these frames were narrow in order to let the bees up into the supers; but on the other three sides they fitted snugly together. The lower edge of the super and the bottoms of the frames rested directly on top of the frames in the hives. When I started to work I tried to pry off a cover with a screwdriver, but didn't budge it. Mr. K. brought a crowbar, and after fifteen minutes of hard work, on a hot day, that cover came loose. Every place was stuck up with propolis. The space between the top of the super and gable cover, as well as the super itself, was full of comb honey which had been built in every direction. I smoked the bees out of the way, cut the combs, and pried loose one

frame at a time as best I could. It was certainly an awful mess, because every frame pulled apart. As soon as the old frames and comb honey, as well as some half-drowned bees from the first hive had been placed in a wash-boiler Mr. K. carried it to the cellar. By the next morning the bees had crawled out on the cellar floor and were easily swept up. If he had taken the honey directly into the house those bees would have warmed up and been harder to handle.

After the second hive was finished I scraped earth over the honey on the ground and took every precaution against robbing. I told him to burn the old frames as soon as he cut the honey out of them, and to be very careful not to leave the frames or any pieces of comb where the bees could rob them out, because it would make trouble with his neighbors. Imagine my surprise, a few days later, to find all the frames and some combs in the back yard—entirely clean. The street must have been a lively place while the bees were getting that honey.

North East, Md.

ANOTHER TESTIMONY IN FAVOR OF "AIR DRAINAGE"

BY JOSEPH S. EWING

I read with interest Mr. E. F. Atwater's article, p. 496, June 15, on air drainage. I want to verify his statement from my own experience. In the enclosed picture of my apiary you will notice part of the hives set out from the building so that the winter wind sweeps around the corner. The others stand back in the corner where there is complete protection from the wind. Last

winter there was no lattice work as shown in the picture. The seven hives that were in the "sweep of the wind" this spring came out in fine condition—scarcely any bees on the bottom-board. On the other hand, the thirteen that were protected had great quantities of bees on the bottom-board, and two hives were dead, the bees being still between the frames with plenty

Sixteen colonies kept in a churchyard close to a hitching-rack that is often full of teams. The bees have made no trouble.

of stores and no foul brood. I can now understand how it happened.

This apiary consists of sixteen stands. It is located in the rear of the Methodist church, the corner of which shows in the picture. The church is located on the corner of two of the most important streets in town (Caldwell has about 4000 people).

The parsonage adjoins the church; the back lawn comes to the edge of the apiary, and a corner of it shows in the picture. This lawn is a playground for the pastor's five children. It is the "social center" for other children in the neighborhood. Their sandpile is 36 feet away. Back of the lattice is a hitch-rack 25 feet away. This is often filled with teams. Some 200 Sunday-school scholars meet in the church and basement. One of the entrances to the Sunday-school room is

not over 15 feet away. Last year there was no lattice between bees and the hitch-rack. No one has ever been stung or disturbed by the bees except on one or two occasions when, in mischief, one of the children disturbed the hives. Bees seem to get used to people and teams. They are Italians.

Caldwell, Idaho.

ACH, DOSE BEES! DOSE BEES!

BY VILHELM BEECUS

Vell, I dunno. I don't belief haff uff vat I hear alretty. I haff been reeting dose beepapers a long vile, und sometimes ago I ret dot der easy vay to make money out uff bees iss to let der bees come und make dere home mit you. Vun feller sess he put up many poxes in der trees und dey vas all filled mit bees unt honey in der twinkling uff an eye. Vel, ven I ret dose beautiful vorts, I set: "Dot iss elekant lankvidge. Dere vas too thousand killed, tree tousand wounded, und sixteen tousand missing. Dey vas all yellow chackets.

A WHOLE HAREM OF QUEENS

BY O. BRONFIELD

On June 25th one of my colonies sent out a second swarm

While the bees were issuing I put on a queen-trap and caught two queens. The swarm settled contentedly, showing that they had a queen. The two caught paid no attention to each other in the trap. When I hived the swarm I found two more queens and let all four go with the swarm into the hive. The swarm refused to enter the hive until I put in a frame containing eggs and brood.

Next morning they swarmed leaving some bees on the brood. I hived them by putting an empty brood-chamber on the hive and dumping them in on the frames, quickly putting on the cover. I then put a queen-trap on the hive.

On June 27 the parent colony sent out another small swarm with three queens. I dumped them, queens and all, on the first swarm, making a fairly good colony with seven queens. This morning, June 30, they again swarmed. The trap caught one queen

Exhibit of J. P. Lucas for the Kansas Fair in 1911.

but others evidently passed through, as I saw two when hiving the swarms. How many remained in the hive I do not know. More bees stayed with the brood this time than before.

I opened the hive and found on the frame of brood seventeen queen-cells, all containing larvæ.

To sum up, several virgin queens lived harmoniously together for five days, and the swarm, meantime, started seventeen queen-cells and swarmed out.

They drew out very little of the foundation on which they were hived.

The bees were Italian hybrids.

Asheville, N. C.

A SENSIBLE AND VALUABLE EXHIBIT AT THE KANSAS STATE FAIR

BY J. P. LUCAS

Many a time I have been accused of allowing my bees to destroy my neighbor's grapes and peaches, so I had a glass hive and super made, and in the hive put a good strong colony of bees; and in the super, as shown in the photograph, a dish of peaches and one of grapes. I thought it would be a novel idea to make such a display for the fair, as it would show the people that bees will not destroy sound fruit. I had the hive at the fairgrounds for a week, and then took it uptown with a nice lot of honey and placed it in a show-window where it stayed two weeks longer. During the three weeks the bees had not touched any of the fruit.

The other illustration shows a part of my display, especially the building made of

extracted honey, which caused lots of comment.

On the end toward the front I had honey produced from 24 different plants, all plainly labeled.

The door and windows were made of wax molded in small cakes, and placed on a board. The roof was made of bottles of honey, and on the sides and the other end I had my honey for competition, while in the background were the dried specimens of honey-plants and fruit put up in honey. I commenced canning fruit in honey five years ago, and have continued every year. So far, all of it, even that which is five years old, is in perfect condition.

Topeka, Kan.

BEES AND ORCHARD BLIGHT

BY E. R. ROOT.

A short time ago a correspondent of the *Rural New Yorker* protested against the attitude taken by editor Collingwood, favoring bees in orchards. The letter sent the letter to me, and asked me if I would present the bee side of the proposition. This I did, and my reply was published in the *Rural* for June 12. See Collingwood's letter in GLEANINGS, page 520. Since that time several have asked me why I did not publish the same or a similar thing in our own journal. Among them is a letter from Thomas F. Rigg, editor of the horticultural department of the *American Poultry Journal*—a journal that A. I. Root says is among the very best of its class. As Mr. Rigg is a horticulturist, and is not particularly interested in the bee side, except for the good it does to fruit culture, his endorsement means something. I am glad to give the letter here; and in doing so I accede to his request. Here is the reply.—Ed.

Mr. Root:—I have just read your article in the *Rural New-Yorker* of June 12, your reply to "I. C. R." of Danville, N. Y., regarding bees and orchard blight. I want to congratulate you upon the able and forceful manner in which you stated the facts in the case. Of course, bees *can* carry blight, and so can numerous other agencies of creation which God in his wisdom placed in this world for doing their work in the interest of mankind. That the bee is of great value and service to the fruit-growers is a fact so well established that none but the very stubborn or uninformed person will dispute it. I hope every fruit and farm journal in America will reproduce your article.

THOS. F. RIGG.
Iowa Falls, Ia.

I notice you have bees in orchard and your approval of the plan. All looks very well and is all right until there comes a year when the blight sweeps over that section as it did through this part of the state last year. This blight is carried by bees and insects; and the more numerous, the more damage. The statement was made on the institute platform last winter that bees in an orchard were a great damage, and that they had done hundreds of dollars' worth of damage in some orchards the past season. As we had a dose of it ourselves, and I spent six weeks cutting out little blighted twigs, and in some cases lost the whole tree, I certainly agreed with the statement, though it was, indeed, a great surprise to me to hear such a statement made, as I had been of the same opinion as you, in regard to the value of bees in an orchard.

Danville, N. Y.

I. C. R.

It is generally admitted by practical and scientific beemen that bees may carry blight; but that they may do the larger part of it is not proven. If all the bees were removed from districts where blight has started, there are flies and other insects, as well as common ants, to scatter blight right and left. The syrphus flies are a common example of a fly that looks very much like a yellow-jacket, and which frequent the blos-

A practical exhibit for a fair. Silent proof that bees do not touch sound fruit.

soms of fruit-trees in early spring.

The writer was called to inspect some pear orchards in central California, in the Joaquin Valley, about 15 years ago. It was alleged that the bees were the sole and only means of scattering the blight; but I proved beyond any question that young trees just set out, and which had never blossomed, were blighted worse than the older trees. Myriads of ants were crawling all over the trees as well as the young ones; and flies of every description, as well as bees, were present in the orchard. The bees were removed to accommodate the fruit-growers; but very little fruit set the following season,

and the pear men were among the first to ask to have the bees brought back. In the mean time, they had neglected to prune off the blighted limbs. Instead, they applied patent medicines; bored holes in the roots of the trees, and poured dope into the holes. The result was, that the blight practically destroyed the orchards. The destruction should not be charged to the bees, but rather to the ignorance of quack doctors.

This matter of blight among ordinary apple-trees comes and goes certain seasons. Some varieties of trees are more immune than others; but even if we admit that the bees do the largest part in the transmission of blight, no less an authority than M. B. Waite, of the Department of Agriculture, Washington, D. C., has made the statement that, even if the bees do carry blight, they are indispensable in most fruit-orchards, especially if the varieties are sterile to their own pollen. In this opinion he is supported by other scientific men and by most of our intelligent fruit-growers. The facts are, bees do ten times more good than harm in an orchard. The great Creator of bees and trees did not intend that they should be out of harmony with each other; and they are not if man understands his job. In the writer's own orchard last season considerable twig blight showed up in several apple-trees. I referred the matter to our State Orchard Inspector, N. E. Shaw, at Columbus. He came down to inspect the trees; and while he admitted there was twig blight and that the bees might have helped to carry it, he told us not to worry about it, as it would probably all disappear another season, and it did. Intelligent pruning, if the blight runs down the larger limbs, will keep the disease in check. Very often careless pruning spreads the blight, because the shears or saws which are used again on other trees carry with them the infection right into the wood. I do not suppose I. C. R. did this; but unless he was very careful to prune clear back of the

blight, and disinfect the tools, he would only aggravate the trouble.

Beekeepers everywhere are being asked to put bees in orchards. We have more calls to supply bees for the large fruit orchards in our immediate vicinity than we can supply. The call has been so insistent from the fruit-growers that we shall need something like a thousand colonies next spring to take care of the demand. One apple orchard of 50 acres grew 16,000 bushels of apples where our bees were placed by request; and we might cite hundreds of instances of a like nature, but we will refer to only one—the famous Repp Brothers, of Gloucester Co., New Jersey. These people raise apples and other fruit by the tons and the thousands of bushels, and yet they say they must have bees and plenty of them. Blight? Yes, there may be a little of it; but what of it? They cannot get along without the bees.

If I. C. R. will cover some of the limbs of his fruit-trees with mosquito-netting the spring before they come into bloom, on varieties that are sterile to their own pollen, he will be surprised to see how little fruit will set. If he needs authorities as evidence, let him consult the Experiment Station at Ithaca, N. Y.; the Experiment Station of Oregon; Horticultural Commissioner Dr. A. J. Cook, of Sacramento, Cal.; and California is the largest fruit-growing state in the Union. In fact, I suggest that he get in touch with any experiment station in the United States. The notion that bees, because they may scatter blight in orchards, ought to be banished is as foolish as it is unwise. If bees are a serious menace to the fruit industry, the great mass of fruit-growers would have discovered the fact years ago; but many of them are asking to have them put on their places. An example of this will be found in the next largest cherry-orchard in the world at Bellevue, Ohio. Bees are placed all over the orchard; and when enough could not be secured some were secured from Florida.

E. R. ROOT.

A HIVE-BOTTOM THAT IS ALSO USED AS A COVER

Some Interesting Appliances for Feeding, Introducing, and Queen-rearing

BY WESLEY DIBBLE

My hive bottom is of uniform size, 16 $\frac{1}{4}$ by 20, and can be used on any style of hive. It is also used as a cover, and I use it for many purposes, as shown by the illustrations. The rim is of $\frac{7}{8}$ -inch material which is the proper height for the feeding-pan accompanying it. This bottom-board re-

quires only a flat surface to stand on for one, two, three, or four hives, and is excellent for the Holtermann winter-stand, four in a group.

The feeding-pan, which holds one quart of sirup, is also a receptacle for a queen-introducing cage, which I use either below

or above the brood-nest for feeding or introducing queens. If the colony is weak I feed below and introduce above. If the colony is strong I feed above and introduce below. I don't meddle with the brood-nest in either operation. I believe I am familiar with all the introducing-cages now in use. If I am not mistaken, they all require opening the brood-nest for introducing queens and removing the cages, which is the cause of losing so many queens in introducing. The cages are so small that only a part of the bees become familiar with the queen.

Dibble's queen-rearing appliances and cylindrical introducing cages. The "incubator" shows but one queen-cage. A dozen or more may be hung side by side.

Studying out this problem of feeding and introducing queens, which I consider the two most essential things connected with successful beekeeping, I have united the two appliances in a very simple manner; and with me I am very successful in introducing queens, not losing one as yet. I perfected this pan and cage last August, and immediately introduced ten queens. All were laying in eight days—my first look at them after introducing. I am certain that this system will introduce more queens safely than any other.

Introducing a queen above the brood nest.

This pan is indestructible. It is manipulated easily, and places the feed right under the bees' noses. Second, the introducing-cage in connection with the pan introduces queens automatically without opening the brood-nest, either before or after introducing, and introduces the queen to all the bees instead of to only a few, as with other cages. For long confinement I use the long cage, which gives the queen full access to the whole length of the hive. The short and medium lengths I use automatically for strong and weaker colonies as required. The bees will liberate the queen in from 48 to 56 hours, if the proper amount of candy is used, and the queen won't leave the cage until the bees will accept her, if left alone. The hive should not be meddled with for a whole week.

By the use of this combined cover and bottom-board I keep all bees on the one stand, if desired, swarm or no swarm; make

The pan as used for feeding above the brood nest.

nuclei, mate queens, supersede old queens without removing the bee-escape; queen-exclude, and other little tricks of the trade. I live in the city of Brooklyn, in the middle of a solid block of brick buildings; yet I have a fair-sized apiary in my back yard, and sometimes on the roof. I need room, and get up and down instead of sidewise; but I hear no complaints from my neighbors about my bees being a nuisance.

A QUEEN-REARING OUTFIT.

The idea of my queen-rearing outfit is old, yet the application is new. It can be used in connection with any strong colony. The cover described above is essential to success. I believe the very best of queens can be reared with this simple outfit if one understands the conditions under which good queens can be reared.

Brooklyn, N. Y.

KEEP THE QUEENS APART

BY W. T. CARY

I tried the Alexander method years ago when it was being generally described in the journals, and I think I thrashed out the principles involved pretty well from all sides to my satisfaction until I made a success of it with a little modification. The modifications, I think, were suggested from articles I read in GLEANINGS.

There are a number of reasons for losing queens; but the principal one seems to be the disposition of the bees. I had some fine gentle Italians, and some blacks and some hybrids, and I found a great deal of difference. I am satisfied that, if my bees had been all gentle Italians, like Alexander's, I should not have needed any modifications.

Use two queen-excluders instead of one, with a bee-space between them. If you have the wood-zinc or wood-and-wire excluder, simply lay one on top of the other. Then provide an independent entrance at the back end for the weak colony. The object of the double queen-excluder is to prevent the queens from getting their heads together and quarreling. If the queens get to quarreling the bees will surely take it up, and a fighting force will go up from below. The object of the back entrance is to enable the fielders from the weak colony to get out without going through the strong colony below where they might get killed and cause a general commotion.

If these manipulations are made at a time when the bees are in a good humor, and all quietly arranged, there will be very little danger, according to my experience. Why? Because the danger resides in the queens themselves or in the fielders, which every beeman knows is the fighting force. The queens cannot get close enough to quarrel, so the fielders in the weak colony will be afraid to go below when they can avoid it, and the fielders below will have no incentive to go above, as they do no house-

work, and their business leads them the other way and to the fields.

Scarcely a bee will pass through the excluders except a lot of young greenhorns that do not know any better than to wander about and take up with any queen or working force that comes handy. Such will be more than welcomed and coddled by the weak colony until they have a strong force that will fight for their adopted mother.

Wakenda, Mo.

BEEES THAT PAID THE TAXES ON THE FARM

BY J. C. DOWNEY

The picture shows my apiary in winter quarters. Three years ago 9 colonies of this apiary produced enough honey to pay the taxes on my 120-acre farm, which is worth \$150 per acre. In 1914 the 19 colo-

nies produced just two pounds, or really one of the 19 did. We had two extremely dry summers in succession here—1913 and 1914.

Jerseyville, Ill., Feb. 8.

A SERVICEABLE BEE-HUNTING BOX

BY M. L. DODSON

When hunting for wild bees I use a box 4 x 6 x 3 inches, made out of light box boards. A piece of glass is cut to fit in sawcuts about $\frac{1}{4}$ inch below the top. The glass should project over one end of the box about an inch to make a handhold. Two blocks, each $2\frac{1}{2}$ inches, are fastened on the bottom of the box, one at each end. This leaves a crack one inch wide and four long. A piece of window-screen four inches square is bent into a V shape and tacked on the ends of the blocks. Three or four holes are punched in the top with a leadpencil. This screen forms an escape leading into the box. Two pieces of old comb are put on the blocks and a little sugar syrup or diluted honey is poured on them and the box is ready for use.

Hold the box over a bee on a flower and it will soon crawl up the screen into the box. When you have caught a dozen or more, and they have started to feed on the bait, release them. They will fly directly home with their load, and every bee will bring back three or four more. When they get well started, close the glass cover, and every bee that returns will find its way up through the screen into the box.

When a sufficient number has been cap-

tured, start with them in the direction the bees have been coming from. Release a few bees occasionally and keep on following them till you come to the tree or house they are in.

They are sometimes hard to follow with the eye, as they will circle around several times before starting home. But if you can keep your eye on them till they fly directly away in a straight line you may be sure that is the right direction.

Another way to get them started is to leave the box in a sunny place for a few hours. If there are any bees in the vicinity they will soon find it, as the smell of the comb attracts them. When they have started, close the cover and proceed the same as though you had found them on flowers.

There are times during the summer when bees will not work on bait, as there is plenty of nectar in the field. The fall is usually the best time to hunt bees.

If you want to save the bees be sure to get them early enough so that they can get established in their new quarters before winter. In the spring, say about fruit bloom, is the best time to get them if you are after the bees.

Jennings, Kan.

CO-OPERATION IN NEW ZEALAND

BY E. G. WARD

The sixth annual conference of beekeepers was held in Wellington, June 2-4. The attendance was slightly smaller than last year, but there was plenty of enthusiasm. The season of 1914-'15 has been one of the worst on record. In the southern districts wet cold weather was the rule, and in Canterbury (middle portion of the Dominion) there were persistent strong northwest winds day and night for several weeks. Dry weather prevailed in the northern districts. One good crop only has been secured, and this from bees located in swampy country—from nothing to half a crop for the remainder.

The conference was opened by the Hon. R. H. Rhodes in the absence of the Premier, Hon. W. F. Massey. He gave figures showing that the industry is progressing on satisfactory lines, and promised careful consideration of any requests or suggestions which might be offered. The president, Mr. James Allan, appealed to those present to allow "brotherly kindness" to

prevail; and it may be said here that the request found favor, for there was a marked absence of anything in the way of uncharitableness.

The annual report showed that the National had been instrumental in arranging for the supply of large quantities of honey for export to the United Kingdom. Negotiations were entered into with Major Norton, representing the Bristol and Dominion Producers' Association, for the supply of not less than 100 tons and not more than 500 tons of first-quality honey per annum for a term of three years at a satisfactory price. As the National Association is not a trading concern, arrangements were made with the New Zealand Co-operative Honey-producers' Association, Ltd., and a contract has been drawn up and signed by both parties.

The New Zealand *Beekeepers' Journal*, which has now attained its first anniversary of publication, was shown to be on a satisfactory basis, and had fully justified its

existence. It will be continued, and several experienced apiarists present promised assistance in writing articles.

The membership has slightly decreased; but two associations had affiliated—the Canterbury Beekeepers' Association and the South Canterbury Beekeepers' Association. There are still three associations unaffiliated, and an effort will be made to induce these to fall into line during the coming year.

Three sessions were held daily, and all were well attended. The incoming executive was instructed to take steps to establish a fund for defense purposes, to be kept separate from the general fund.

It was announced that amendments to the Apiaries Act would be gazetted shortly, and that the registration of apiaries would be included. This has been urged by several conferences, and the announcement was greeted with applause.

A number of valuable and instructive papers were read at different times, notably "The Food Value of Honey," by Mr. B. C. Aston, F. I. C., B. C. S.; "Co-operative Selling Propositions," by H. W. Gilling; "A Short Cut in the Treatment of Foul Brood," by C. J. Clayton.

The evening sessions were chiefly given over to discussions on various subjects connected with bee management. Of special interest was the discussion on "Can we Improve the Flora of our Districts to Provide Higher Qualities of Honey?" and "The Importance of the Honey-bee to the Fruit-growing Industry." Mr. W. E. Barker, Peel Forest, who is an authority on New Zealand flora, was particularly interesting in his remarks; and M. J. Rentoul, Cheviot, ran him very close for first place.

The conference resolved to recommend that the water content in honey, to comply with the provisions of the pure-food act, should be reduced from 26 per cent to 20 per cent. A number of samples of New Zealand honey had been analyzed, and were found to vary from 14 to 17 per cent.

Mr. F. A. Jacobson, government grader, gave a demonstration of grading honey for export. He explained the methods and how points were allotted.

In the second day of the conference a special general meeting of the shareholders in the New Zealand Co-operative Honey-producers' Association, Ltd., was held. The Dominion has been divided into seven districts for the purpose of dealing with local trade. Directors were elected to represent the various districts, and resolutions submitted provided power for a committee of three to be appointed to manage the com-

pany's affairs in each district where a bottling depot is established. It is hoped that, next season, depots will be an accomplished fact in two districts at least, in addition to one already running in Taranaki.

On the last day a presentation of a traveling-rug was made to Mr. Isaac Hopkins, and a trinket to Mrs. Hopkins as a small token of the esteem in which Mr. Hopkins is held. On account of the war, Mr. Hopkins' departure for England has been delayed indefinitely. In making the presentation, Mr. Allan, president, made feeling reference to the kindly feeling beekeepers have for Mr. Hopkins, who is known as the father of beekeeping in New Zealand. Mr. Hopkins thanked the donors very heartily, and related a number of anecdotes connected with beekeeping in the early days.

The following officers were elected for the coming year:

President, J. S. Cottrell; vice-president, M. J. Rentoul; North Island representatives, Mr. Askew and W. J. Nicholas; South Island representatives, Mr. W. E. Barker and W. B. Bray; general secretary, Mr. Stewart Wright.

St. Albans, Christchurch, N. Z.

NIGHT

BY GRACE ALLEN

In the mystical hush of the night I pause
And send my thoughts round the curve of the world;
Here there is silence and slumber around
And moonlight for miles unfurled.

This part of the world is asleep, so still
One scarcely remembers the throb of the lives
Of millions of men at rest in their homes
And millions of bees in their hives.

Then out past the night my thoughts sweep on
And pause where the dawn of a day has begun,
Where strong men waken and children spring up
And bees flash out in the sun.

Then swifter than light my thoughts race on
Where for thousands and thousands of miles it
is day,
With traffic's roar and the rush of the town
And the bees in fields far away.

Still on and around my swift thoughts trail
Till they sink at last with a setting sun,
Where work-wearied men and homing bees
Seek rest, and the day is done.

"And ah! through it all," I think "through it all,
Is life and love and death and birth,
And a million of men and a million of bees
And the mystery of the earth!"

Heads of Grain from Different Fields

The Backlot Buzzer

BY J. H. DONAHUE

Dogs wag their tails and folks smile when they express their pleasure; but whatever induced the bee to stand on its head and wiggle its wings?

Wants Definite Figures on Honey-selling

A matter that is often neglected in the bee-journals is the matter of putting up and wholesale selling of extracted honey. Let us have facts and figures.

Let's start with an amount of honey, say ten or twenty cases (1200 or 2400 lbs.). Suppose one buys at the market price direct from the producer. It is worth just as much if the producer is the bottler also. It is necessary to pay freight on honey, buy glassware from any of the supply catalogs, pay freight and breakage on glass, and to heat, strain, and clarify honey. Take into consideration the labor at a fair amount, and the depreciation of equipment. Next will be labels and cases if glass is ordered in crates, applying labels, cleaning glass, and filling glass. Now comes the selling part. Either advertising or soliciting orders will be demanded. Delivering or freight should also be taken into account.

Will some one be so kind as to give us information on all these lines?

It seems we are too much on production and not enough on uniform price and distribution.

NET-WEIGHT LAW O. K.

I observe that an effort is being made to have sections weighed in with the honey as a comparison to the wrapping around hams. Please take into consideration that the wrapping weighs perhaps 3 or 4 ounces to a ten or twelve pound ham, while the section weighs 1 ounce to every 10 or more ounces. I am in favor of the net-weight law as it stands, requiring the producer to mark the exact net weight on each section or other package. Give the consum-

er a right to know how much he is buying. It is only fair. We all like to know what and how much we are getting. If the producer can see no other way to get pay for that ounce of wood, let him ask a cent or two more for his honey per pound. They don't complain if you explain the matter.

Akron, N. Y.

WILLIAM VOLLMEER.

Cotton Cushions All Right, but the Bees were Too Old

From our experience with cotton cushions we find, first, they act as a heat-retainer; second, they are a moisture absorbent; third, they are clean and light in weight. Our combs are dry, and free from mildew where bees have died. The same dry condition is found in hives where bees are alive. We use an all-over deep casing, the same as Mr. Martine speaks of in the March 15th issue. In the month of January, when there was an outside temperature of 19 degrees, we found that we had a temperature of 72 degrees on top of the cushion.

But in spite of all these perfect conditions our loss has reached 50 per cent. Some of the old-timers may wonder why this is so. Which has the greater vitality—a horse 25 years old or one 5? Knowing what a poor year 1914 was, we have the story in a nutshell. Old bees to the extent of 60 per cent, when going into winter quarters, are beyond wintering.

Our queens stop laying in September. We started to feed up. We fed some 1000 or 1200 lbs. of syrup, but, no use. There was nothing doing. Our bees started brood-rearing the middle of January.

H. G. Quirin agrees with us as to the cause of the loss. He uses the tenement hive, or four-hive winter case.

Bellevue, O., April 10.

Net-weight Law in Florida

Florida beekeepers should notice that all packages sold or for sale must have net contents of same stated in weight, measure, or numerical count, conspicuously, legibly, and correctly, on the outside of the package. This law was passed by the Florida legislature in 1913.

Apopka, Fla.

FRED E. MARDEN.

Tartar Emetic for Ants

I was troubled very much with ants in my honey department. I was advised to get ten cents' worth of tartar emetic and scatter it lightly in the honey-house or put it into small dishes, adding a little water. In three days not one ant was left.

Conesus, N. Y., Aug. 18.

D. W. TRESCOTT.

Belligerent Bees

At one time I thought I had tame bees, but a recent swarm certainly disproved this idea. It settled on a Norway spruce tree about 30 feet aloft. I took a ladder, set it up, and fixed myself with bee-hat, gloves, etc., and thought I was in good shape.

I began sawing off the limb; then the fun commenced. The bees went after me by the hundreds, my gloves were covered with bees stinging for all they were worth, and my hands felt as though they had no gloves at all.

I thought of the Backlot Buzzer and took courage. I got the limb down, but it had few bees on it. Then they discovered my cotton socks. I never was a dancer, but I could have danced that time without

music. I did not get the queen, so they went on another spruce tree, and settled in three bunches near the ground. This time I took a wash-basket and a hoe, and knocked the largest bunch into the basket. I dumped them in front of the hive, but that time they found a way through my hat, and turned their artillery on my face.

I do not think I need to be stung by any bees to keep rheumatism away for some time. I wish some one would tell me why those bees were so cross. We had a storm that night, and a cold rain for several days.

J. B. VOGELBACHER.

Field Meeting at Pembroke, N. Y.

The field meeting and basket picnic held at J. N. DeMuth's apiary at Pembroke, N. Y., under the auspices of the Western New York Honey-producers' Association, was very well attended in spite of the rainy weather that prevailed in the forenoon. The fore part of the day was mostly getting acquainted and renewing old acquaintances, which always seems to be a jovial reunion when beekeepers meet.

Messrs. Vollmer and DeMuth removed several supers of honey from the hives, brushing off the bees with a brush of their own design, which certainly has the old hand method stripped outright.

Several colonies were examined and queens found. Some present favored three band and some the goldens. Mr. G. C. Greiner told of his victorious campaign with European foul brood four years ago. Mr. J. Roy Lincoln also related his experience along the same line. All seem to agree that a vigorous strain of Italians is needed to clean up the disease and hold it in check.

Mr. J. T. Rasch told of his method of rearing queens and building up nuclei—a line in which he specializes to quite an extent, as he usually sells bees every year. Mr. L. F. Wahl also exhibited some of his handiwork in the queen line, which was certainly fine. He also does quite a large honey business, putting up considerable in quarter-pint milk-bottles for the trade.

While this was a basket picnic, Mr. and Mrs. DeMuth deserve special credit for lunch and refreshments they served to those who were inconvenienced or forgot to bring some. Several members were added to the association. This field meeting is to be an annual feature.

Akron, N. Y.

WM. F. VOLLMER.

The Cost of Bees and Drawn Combs

In some cases the answers to questions on bee values, page 419, do not seem to cover the points quite satisfactorily. Replying to 1 and 5 you say that in the spring there would not be 30 or 40 lbs. of honey in the combs. True; but I suggested that, as a business man, if you wintered bees on this amount of honey, and then sold them in the spring, you would naturally add the value of the food consumed—in this case about \$6.00. You cannot have your pie and eat it too.

Of course I was in each case speaking of "things as they are" in British Columbia. Beekeepers here have not yet accumulated large surplus stocks of brood-frames, and there is always the risk of foul brood in disused frames, which, generally, come from hives whose former inmates have died.

Somewhere (in the A B C, I think) I have seen a certain beekeeper's success attributed largely to the fact that he possessed some 2000 surplus brood-combs. Now, at the low price of 25 or 35 cents (your figures) each, one might easily procure a like supply, and so swell the ranks of the successful ones, but that is not feasible here.

The market price of beeswax is admittedly low, and I understand that the amount of honey con-

sumed by the bees, in proportion to the wax secreted, is not definitely known (1905 edition of the A B C, glossary, p. 407, says, "The production of each pound of wax requires 10 to 20 lbs. of honey"); but we will say it is 10 to 1—that is, on our values of honey at 17½ to 20 cts., wax should be worth over \$2.00 per lb., especially in view of the time consumed by the bees in the cluster. This brings me to my point—viz., I can buy foundation at about 70 cts. per lb., but I cannot get the extra wax added to it in the drawing-out and building process for less than \$2.00 per lb.; and I think that this fact goes a long way to prove my contention, that 67 cts. is not a high value to put on a good frame of worker comb. They cannot be manufactured by machinery, and we do not care to try importing them for fear of disease, which we are especially anxious to keep out (or clear out) of British Columbia, hence it looks like a corner in combs in favor of the happy possessor.

As a matter of fact I value my combs at \$1.00 each. They are ready for any emergency, and would be hard to replace. Let me whisper here that the honey crop in this district is a practical failure; and it was for only a very short time, during fruit-bloom, that the bees worked at drawing out foundation.

I know of folks who imported bees by weight, put them on foundation, and lost them by starvation for this very reason.

Like so many problems in bee culture this seems to depend largely on locality. Yours may be an exceptionally difficult one.

North Vancouver, B. C.

FRED E. WHITE.

Old Story to Him

The method of swarm control proposed by Mr. Chalton Fowls, page 574, July 15, is practically the same plan I have been following for the past two years without knowing that Mr. Fowls or any one else had been practicing it.

The only difference is that I do not remove the top super of brood unless I want increase. Furthermore, I work the bees on this plan even before they start queen-cells. I seldom have a swarm, but secure good crops of honey. I keep the hives raised up on small blocks. This plan works well with such prolific breeders as Carniolans and Caucasians.

The "Long-idea" hive appeals to me for the following reasons: There are no supers or queen-excluding boards to remove when one desires to examine the brood-nest or requeen. It is very easy to transfer frames of brood from side frames or to side frames or supers. One can handle many more Long-idea hives in a day than the present style, and give better attention to each. There are no supers to store away nor carry to out-apiaries. I expect to test one the coming season before I purchase a further stock of the present style.

Andalusia, Pa.

H. W. FULMER.

An Experiment to Get Rid of Laying Workers

Having found a hive containing laying workers I first introduced a frame containing eggs and brood to see if queen-cells would be started; and on finding the case hopeless I referred to the A B C and X Y Z of Bee Culture without getting much encouragement from it. It occurred to me that the laying workers probably develop the instincts of a laying queen, and so would tend to remain in the hive on the combs and not go abroad seeking nectar as do their fellows. Reasoning thus, I moved the hive to an out-of-the-way spot with its entrance facing in a new direction, and there shook all the bees off the combs into the hive. I then removed all the combs except one containing drone brood which I left in

the hive to act as a bait for the laying workers. I next placed a new hive on the old stand, giving it some frames with eggs and brood to see if the field bees on returning would start queen-cells. I was much pleased to find the plan successful and queen-cells started, and so gave a ripe queen-cell which duly hatched, and the queen was accepted.

To return to the old hive with its single frame, I found there sufficient bees to cover only this one frame, and to save these I shook them up with the bees of another hive in the apiary with which they united quietly and peaceably. This latter plan may be dangerous, as the laying workers might kill the queen in their new quarters; but I felt the chances were against it, which proved to be the case. The whole plan was extremely simple, and proved very effective; and I hope if any of your readers try it they may also report success.

C. HOGAN, Sec. Annapolis Valley Branch Maritime Beekeepers' Association.
Port Williams, Nova Scotia.

The Beekeeper's Opportunity

With a bountiful harvest, and the market anything but favorable on account of the European war, beekeepers have an excellent opportunity to try advertising as a means of disposing of their honey. The consumers would use more honey than they do at present if the many excellent points of this article of diet were kept more constantly before them. Think of the "slump" in breakfast food sales if the manufacturers were to cease their advertising for a month!

Mr. W. W. Lourance, of Centerville, Texas, has for several years past sold his honey by inserting the following small advertisement in the classified columns of a farm paper which circulates largely among the Texas cotton, fruit, and truck growers:

Honey that will please you at right prices. Bulk comb and extracted; one-gallon pails, five-gallon cans, freight paid.

HONEYDALE APIARIES, Box 43, Centerville, Tex.

"We have been blessed with a bountiful harvest this season," says Mr. Lourance. "And I find this little advertisement one of the best means in securing a market for my honey."

The newspaper offers the man with honey to sell a medium by which he can multiply his possible customers from a few hundred into many thousands. Too long have we neglected to use this powerful means in helping to secure a market for our products.

Beville, Texas.

MAURICE FLOYD.

Why Robbers should Not be Trapped

In *GLANINGS* for October 15, last year, I noticed an article bearing the title "Trapping Robbers Not Recommended;" and the answer given by Chas. H. Cargo as follows: "Because it puts the bees in an interior hive while killing out another and stronger hive."

If it is one of his own colonies that is doing the robbing, then he does not lose much by letting them rob; but if it is some other beekeeper's bees that are doing the robbing, then he loses all but a little comb that may remain in the hive after the robbing. Robbing bothers but little the beekeeper who is on his job.

I would not recommend trapping robbers, because it may lead to the trapping of not only robbers but bees that are in search of food for the purpose of building up new colonies at some other beekeeper's expense or loss.

I took an empty hive, put some honey in it, and set the hive outdoors where my neighbor's bees could get at it. By leaving the entrance open for

twenty-four hours or longer, thousands of his bees found the honey and were at work carrying it away. But I soon stopped this by putting three robber-traps (Porter bee-escapes) into the entrance of the hive. In a few hours I had a hive full of trapped bees. Now, all that I had to do was to introduce a queen, then I would have a new colony at my neighbor's expense; but, no—I let them go. It was an experiment that I was trying, and I found that it worked. But there may be people who would trap bees for the purpose mentioned above if they only knew how. So it would not be wise to recommend trapping robbers.

Meadville, Pa.

A. B. MCGUIRE.

Fall Honey-plants

Oakland County, Michigan, should have been named Lake County, as there are 283 named lakes and 100 that are not named. Around these lakes are acres and acres of wild flowers, such as golden-rod, wild asters, boneset, and a plant that resembles boneset very much, and from which the bees gather large quantities of honey of a light-amber color. There is a plant that has a small white flower, and blooms after the frost kills the others. I have seen bees on this plant up to the first of November, and have counted seven bees on a small twig. There are hundreds of flowers on a single plant. Then we have a plant that grows 5 to 7 feet high that has a blue flower on which the bees work in large quantities.

There are 50 different varieties of goldenrod alone, besides different varieties of asters, boneset, spearweed, buckwheat, and several other kinds of fall flowers that grow around these lakes in great abundance. The goldenrod is just coming into bloom now; and if the frost holds off, and we have warm weather during the next two weeks, thousands of acres can be seen.

I have taken 30 lbs. per colony of extracted honey from these fall honey-plants, after leaving 25 to 30 lbs. to winter on. The honey is very thick. If left on the hives until it is all capped over, it is almost impossible to extract it. In the northern part of the state there are thousands of acres of waste land—yes, hundreds of thousands of acres—that was timbered over and that have gone back to the state, as the owners would not pay the taxes on it. The waste land has grown up to wild red raspberries and other wild flowers.

The lamented W. Z. Hutchinson took 15 colonies up to this waste land and increased them to 150, and wintered the 150, then got a large crop of honey, and sold it at 10 cents per pound.

Rochester, Mich., Aug. 28.

J. M. KINZIE.

Robbing

Occurred in late September, when the days, as I remember, were shading, growing cooler, with the frost not far away. I enrolled my hives in number 'fore I left them to their slumber, and prepared them for the coming of their resurrection day.

Heard a wicked little bee with her hum exultant-ec had been tipping in the barroom of an undefended hive. Somehow so it chanced as into hives I glanced, I was tackled, worsted, routed, scarcely saved myself alive.

Garbed with yards and yards of netting, veil and smoker not forgetting, forth I beat it to the riot like a Yaqui to the fight. First the entrance neatly covered where the robbing I discovered; left them shrouded with the netting till the coming of the night.

When the evening lamps were lit I could feel that all was fit. My forty hives I'd cellared, and was left in peace to sit.

OUR HOMES

Editor

Thy kingdom come; thy will be done in earth as it is done in heaven.—MATTHEW 6:10.

There shall in no wise enter into it anything that defileth, neither whatsoever worketh abomination, or maketh a lie.—REV. 21:27.

God's kingdom is coming. You may remember that I have used this phrase frequently of late; and day by day I see new evidences that God's kingdom is coming, here on earth, in this teeming world of ours. It is coming to the state of Ohio; and the time of its coming depends on the people, on humanity. It depends on *you* and *me*.

I have just returned from a visit to the Ohio State Fair. I think it must be ten years or more since I looked over the Ohio State Fair; and I was astonished and happily surprised to see the movement that is going on toward God's kingdom.* Before I tell you what I saw let me explain a little.

The liquor party is becoming alarmed. A year ago they started what they called "home rule" here in Ohio, to hold back prohibition. Thousands of people were deceived and deluded about the so-called home rule. Well, it worked so well they have just now, before the coming contest, started what they call "The Ohio Temperance Union." That sounds good, does it not, friends? Well, their first move was to go down to Greene County and put up a tent or a booth on the county fairgrounds to distribute their "Ohio Temperance Union literature." The managers of the fair, however, when they caught sight of that lot of temperance(?) literature, called a halt; and their tent, bag, and baggage were very soon ruled off the grounds. They made a big fuss, called the managers fanatics and various other names; but that did not help their cause. Well, the papers tell us they made a venture at another county fair and with the same result; and then this Ohio Temperance Union had the audacity to ap-

ply for space at the Ohio State Fair; but when they produced some of their literature the managers of the fair promptly declared that no such temperance literature could be placed on the grounds of the Ohio State Fair. The liquor men put up a big remonstrance, of course; but the managers were "hard-hearted."

Well, when I approached the gate at the State Fair on the last day of August, the most conspicuous object was a good-sized building outside of the fairgrounds, just as near the entrance as they could get, decorated with the Ohio Temperance Union literature. While there were thousands upon thousands of people rushing through the gate, I did not see anybody gathering around this great display of print. On the morning of Sept. 1, when I came up to the honey exhibit in the Exposition Station Building one of the young beekeepers placed in my hand a clipping from a Columbus morning paper. I am sorry he did not leave any evidence as to the name of the periodical. Here is the clipping:

REMOVAL OF 7 MEMBERS OF AGRICULTURAL BOARD IS ASKED: OHIO TEMPERANCE UNION CHARGES THEM WITH HAVING FAVORED PROHIBITIONISTS.

Removal, not of the entire ten members of the State Board of Agriculture, but of seven members, President John Begg, C. A. Branson, N. L. Bunnell, J. W. Kirgan, D. D. Snider, T. B. West, and K. D. Williamson, was demanded yesterday of Governor Willis by Harry R. Probasco and W. L. Casady, managers of the Ohio Temperance Union, because the union had been denied a 12-foot space on the fairgrounds on which to set up a tent and distribute arguments against prohibition.

The managers ask removal if the governor does not force the board to recede from its action or does not obtain the resignations of the seven. Though it is not specifically stated in the demand, it is understood the seven voted against the concession Monday when nine members were present.

The managers charge discrimination in favor of the Woman's Christian Temperance Union, which has a booth on the grounds and is distributing prohibition arguments.

Did you ever see such a display of what is generally called cheek? The idea! "Discrimination" indeed, in favor of the W. C. T. U.!

Some years ago when traveling on a railway where I was pretty well acquainted, I noticed a change of conductors. When I

*To-day, Sept. 6, we find the following in the *Cleveland Plain Dealer*:

AVIATORS TO AID WETS.

The Ohio Temperance Union, which is fighting the prohibitory amendment, being denied space inside the fairgrounds to distribute literature, seeks to employ aviators to fly about the grounds and drop quantities of literature on the heads of the crowd.

The Anti-saloon League will ask the courts to stop that procedure.

* When I approached the gate to the fairground a great number of men and boys pushed out to me various leaflets, advertisements, etc. At first I commenced to shake my head; but finally I decided to see what they had for sale, and crammed a great lot of them in my pockets. When I got time I noticed they were advertisements of medicine to cure rheumatism, tuberculosis, cancer, headache, etc. They "stood outside the gate" because the management did not allow anything of that kind on the ground. As soon as I got inside I saw men with baskets of waste paper going around with a sharp stick and spearing up paper bags and trash of all sorts as fast as the busy crowd dropped them. I commenced to pare a nice apple; but almost as soon as the peeling reached the ground a couple of alert boys with baskets caught up the peeling. It was so all over the fairground. No trash or untidiness was permitted to accumulate. These are trifling matters; but even "straws," you know, "show which way the wind blows."

inquired what had become of my former friend the reply was, "He was dropped because he was color-blind."

"Color-blind?" said I. "What do you mean by color-blind?"

I could readily understand why an engineer should be dismissed on account of being color-blind; but I could not see how it applied to a conductor.

"Why, his color-blindness was like this. He got so he could not discover any difference between the color of his own money and the money belonging to the company."

Now, while we shall have to admit, perhaps, that a good many of our Ohio people were color-blind a year ago in regard to "home rule," for instance, I doubt if there were many in the great throngs on the grounds of the Ohio State Fair this year who failed to see a difference in the color of the literature passed out by the Ohio Temperance Union and the literature used freely in the building and all over the fairground by the W. C. T. U. By the way, let me remark that in times past the W. C. T. U. has been laughed at and ridiculed; but just now, thank the Lord, they are "coming into their own" here in Ohio. Their presence and their good work were manifest all over the fairground, inside the buildings and out, in the way of resting-places for women, an immense dining-hall entirely under the management of the W. C. T. U., etc.; and very likely the good women of Ohio inaugurated the scheme of gathering up the rubbish as mentioned in the fore part of this article.

I am not going to tell you all I saw nor even a part of what I saw in that great accumulation of the best things that Ohio can produce. I am going to confine my remarks chiefly, at least just now, to what is called the "Education Building" of the State of Ohio. Near the entrance to this great edifice we see "Safety First" given a prominent place. In fact, "Safety First" seemed to be the most prominent feature in the education of our boys and girls as well as men and women. Now, what do you suppose the state of Ohio recognizes as of the greatest importance in this matter of safety first to conserve human life and limb? In my Home talk in our last issue I gave a list of the things that the Pennsylvania Railroad Co. is doing and has been doing for years past to make *safety first* the great slogan of their thousands of miles of railway. Well, I thanked God again and again that the *factories* of Ohio are recognizing that safety first demands the entire abolition and prohibition of intoxicants. One of the first things that caught my eye

was a very pretty motto in large plain letters: "If you would not marry a girl who drinks, why should you expect a girl to marry a man who drinks?"

May be, friends, you do not see what a tremendous bearing safety first cuts in the above. Look at that picture in the last GLEANINGS of the girl amid the flowers, and read what is written under it. Well, there is one whole department devoted to infant mortality. Another motto over this reads, "Nine babies die from overfeeding where one dies from lack of nourishment." Over another department we read, "Eighty thousand accidents in Ohio during 1914 cost the employers of factories over three millions of dollars. Why not help to reduce this appalling record at least a half?" On another very pretty card we read: "Workmen who are not careful from 5 P. M. to 7 P. M. will not likely be careful from 7 A. M. to 5 P. M." The inference is that the man who thinks he can visit saloons after working hours, and that it is nobody's business, is just now finding out he is mistaken.

The United States Steel Corporation had a magnificent display. There was no end of photographs explaining how accidents happen that proved injurious or fatal. As an illustration:

Where workmen are working steel with a cold chisel, chips of steel often get into the eye. This has happened frequently in our own machine-shop. Well, the management now furnishes stout glass goggles with placards requesting employees to use them whenever the eyes are in danger, and the broken spectacles are placed in plain sight, showing where the chipping fractured the glass instead of putting out an eye. I remarked to the bright man in charge that our institution was employing workmen, and asked him how they managed to keep intoxicants away from their help. His reply was, as nearly as I can recollect, as follows:

"Mr. Root, we are just now getting material to put up a stout barbed-wire fence clear around our premises. Workmen are to be admitted through a gate; and after they are all in, the gate is locked. A man cannot get out without giving a reason for it until the gate is opened when the whistle blows. If saloons are planted in the immediate vicinity of our premises we will establish a watch; and when any one of our workmen goes into one of these saloons he is promptly dismissed."

You see a saloon would be unlikely to locate in such a place if they knew of the regulations beforehand; and if they did have the audacity to locate thus the mana-

ger would probably soon go away on account of a lack of patronage.

I hold in my hand a sort of magazine of toward 100 pages. It is the Safety Bulletin of the Ohio Safety Commission. In one place we read:

Ohio's opportunity to conserve human life and limb.

That prevention of accidents is of even greater importance than equitable compensation to injured workers.

The value of men, women, and children in our country is worth in money more than twice as much as are our industries, railroads, land, buildings, and improvements. No monetary value can be placed on the health and happiness of humanity.

The whole periodical is devoted to safety first. On page 74 we read:

"If past experiences enable us to judge, more than ten thousand workers of the United States who are alive and well to-day will be *dead one year from date*, just because they failed to heed the most simple and obvious precautions of 'Safety First.'"

For copies of this magazine address Victor T. Noonan, Director of Safety, Industrial Commission of Ohio, Columbus, O.

Now, all of these things admonish me that God's kingdom is coming. Not only the state of Ohio, but the whole wide world, seems to be waking up and recognizing as it has never done before what intemperance has been doing for ages past in the way of preventing the forward movement of the gospel of Safety First. Do you want to know what will be the state of affairs in that happy time when God's kingdom shall come in earth as it is in heaven? Well, I have at present only a dim vision of what this earth will be; but I get a glimpse occasionally of good men and women who really do love their neighbors as themselves—who really do love the boys and girls of coming generations as they love their own children and grandchildren, who have been able to follow the gospel of Christ Jesus and its injunctions to love *even our enemies*—the enemies they are compelled to fight—the enemies of all righteousness; and we are just now working to make Ohio dry without any fight or ill will toward the brewers, the saloon-keepers, the liquor-dealers, and all who are engaged in that unholy traffic. We love them in spite of their greedy, selfish, unhappy nature, and we long to see them engaged in some pursuit where they will be better men and better women. We long to see them engage in some pursuit where they can honestly ask God's blessing on the goods they send out—in some pursuit where they will not feel that they themselves, their wives and their children, are disgraced before all good men and women, when the nature of their occupation becomes known.

Now in regard to the condition of affairs

when God's kingdom shall have come in earth as it is in heaven, I cannot tell very much about it except from the many glimpses that we get through God's holy word.

As I think it over after my brief visit I have been wondering if the time is not near at hand when not only our state fairground but the fairground of every fair in Ohio shall come up to the standard as we have it in Holy Writ.

"There shall in no wise enter into it anything that defileth, neither whatsoever worketh abomination, or maketh a lie."

I confess it may be a pretty big jolt for at least some of our county fairs, and even state fairs, but evidence seems to be growing all about us that the time is approaching when God's kingdom shall come to even this earth of ours.

APPLE JUICE "WHILE YOU WAIT."

The principal beverage on the State Fairground was so-called apple juice squeezed out of the apples while we stood by. For instance, I went up to a refreshment stand and picked up a nice apple and handed out some change. The proprietor instantly said:

"No, no! those apples are not for sale."

"Not for sale?" said I in surprise.

"No, we want them for cider; and with our big trade it looks as if we would not have enough any way."

"Well, if you do not sell the apples, will you sell me some of the juice out of them?"

"Oh, yes! we will sell you the juice—that is our business."

It was just about my supper time, and my supper, as you may recall, has been lately mostly of apples; and I was wondering if the juice of apples would not do just about as well as the apple itself. Of course he put several more apples with it, and gave me so big a glass of cider that I was afraid I should not be able to drink it all, especially as it was ice-cold. So I sipped a little slowly, for it was a warm day, and I am afraid of ice-cold drinks at such a time. I am glad to say that the apple juice seemed to answer just as well as apples. Had I been at home I would have had a little bit of cheese with the cider; but I got along very well with just the apple juice. Now, there is certainly no objection to giving a man, woman, or child all the apple juice (perhaps I should say at proper hours) that they care for. But the use of cider has been discouraged of recent years, because there is so much danger of its being kept until it is fermented, or slightly so; and *hard* cider in times past has made about as much trouble as beer—may be more.

There were many stands for the cider while you waited, all over the grounds. They had a fashion of pouring it quite a distance so as to make a foam on the top of the glass so as to look like a glass of beer or a glass of fermented cider. But I think the authorities looked after things so that no cider was on sale anywhere that was the least bit worked. It was just plain apple juice, and made a very nice delicious drink, made of apples neither too sweet nor too sour. All the stands used a small cider-mill worked by hand; and it would be very nice to have such a machine—a very little one—in the home if it were not for the danger of keeping the cider until it contains alcohol, and if public sentiment were worked up to such a point that our fathers and mothers could look out and prevent a little cider-mill proving to be a thing of danger in the home.

JOHN L. SULLIVAN, THE CHAMPION PRIZE-FIGHTER, TALKING ON TEMPERANCE.

Strange things are happening nowadays, and, thank the Lord, some of the happenings are "happy surprises." In a recent *Rural New-Yorker* the Hope Farm Man tells of attending a temperance lecture at Ocean Grove, N. J., where Sullivan was the speaker. I wish our readers could all read that Hope Farm notes. We have room for only two brief extracts.

Here was a man who in the palmy days of his great power spent at least half a million dollars for liquor in the meanest and most debasing way, and then finally braced up and "cut it out" as he expressed it. Surely, we have here an expert whose opinion ought to be worth something. He said the only safe way to fight "booze" is to jump out of the ring and run for your life. He said, and he ought to know, that the man who says, "I can take a drink when I want to and quit when I want to" is a fool and a liar! I was impressed with what Mr. Sullivan said about the growth of prohibition sentiment everywhere. I had to rub my eyes as I recalled that railroad scene of 30 years ago, and now saw this white-haired, earnest man waving that great hand with something of prophecy as he said that within a few years the sentiment against the useless folly of "booze" would be so great that decent men will not stand for it.

From a recent number of the *Cleveland Plain Dealer* we clip the following:

MORE ABOUT KANSAS.

In a recent number of the *Plain Dealer* Paul S. Conway, of Kansas City, is reported as having stated in an address to the "wets" of Cleveland that last year over 90,000 gallons of whisky was drunk in Topeka, Kan., that the saloons of that city were wide open, and that more liquor was sold in prohibition towns and cities than in cities where open saloons exist.

I have spent a number of months each year for several years in Topeka, and know, as every person

who is acquainted with the city knows, that there are no open saloons in Topeka; that "the city is as tight as a drum," to use the language of the present mayor of Topeka, and that the prohibition law is as well enforced there as is the law against burglary or larceny.

In further reply to Mr. Conway permit me to quote from the speech of Arthur Capper, the governor of Kansas, made on Kansas day at the Panama-Pacific exposition in San Francisco. Mr. Capper is the owner of the *Topeka Daily Capital* and other publications having a statewide circulation, and has spent his entire life of fifty years in that state. I quote from his speech as follows: "Kansas for thirty-five years has not had a legalized saloon or brewery, and now has eighty-eight city and county jails that are empty, forty-seven poorfarms and almshouses that are unoccupied; twenty-eight counties in which the criminal courts have not had a criminal prosecution in more than a year; there are more than half a million boys and girls in the state who never saw an open saloon; the state has the lowest death rate in the United States, only seven to the thousand, a percentage constantly decreasing, although we have more motor cars in proportion to the population than any other state. Kansas has the largest per capita of wealth, almost \$2500 for each man, woman, and child within its borders, while we have \$205,000,000 of surplus wealth piled in our banks and savings institutions. Kansas was the first state to declare unanimously through its legislature, its state officials, and its entire delegation in congress for nation-wide prohibition."

No attempt has been made, and no successful attempt can be made to refute these and other statistics of like import given by the governor before a large audience, including several hundred prominent jay-hawkers who were present on that occasion.

Ashtabula, O.

NORRIS L. GAGE.

THE DOPE HABIT.

We clip the following from the *Official Bulletin of the Ohio Agricultural Commission* for July:

THE DRUG HABIT.

Ohio, as well as other states, has an army of human beings who are more or less slaves to the "drug habit." The Division of Dairy and Food Inspection, under Mr. Strode, has charge of the enforcement of stringent laws recently enacted. The "drug" is now hard to get. Yet some folks who want to be regarded as respectable and honest will, for the greed of a dollar, aid and abet these drug victims to get the drug in defiance of law.

This curse has cast a shadow across Ohio and the nation. The cities, especially, have a large percentage of the cases and victims. In many cities the prisons are filled with these unfortunates. The state and nation ought to have started twenty years ago to wipe out this vice.

Mothers will appeal to officers of the Agricultural Commission for permission to purchase "drugs" when they find they cannot get them as they formerly did. They threaten to destroy themselves. They say they want to live for their children, but cannot live unless they can have their "drug."

One half of the people do not know how the other half lives.

The above is all very good; but does it include cigarettes as well as morphine, cocaine, etc.? May God help us in our efforts to keep temptation far away from the path our children are treading. "Lead us not into temptation," etc.

HIGH-PRESSURE GARDENING

TRAMPS: WHAT SHALL WE DO WITH THEM?

ALSO SOMETHING ABOUT SOWING

SWEET CLOVER BETWEEN THE

HILLS OF MATURING CORN.

We clip the following from the *Cleveland Plain Dealer*:

One who gives a tramp a "hand-out" at the back door is doing himself, the tramp, and the community an injustice. A city which, rightly or wrongly, gains the reputation of being composed largely of these back door philanthropists suffers in the long run, for hoboes are persistent advertisers. They spread far and wide the glory of any city which shows special consideration of their kind.

I think there must be considerable truth in the above, because I have noticed tramps passing by our place and stopping at some of the humbler homes on the outskirts of our town. Very likely it is understood among the craft that our establishment offers *work*, but not cold victuals. But I am glad to say that I have had one experience that I am glad to mention. Monday morning early a fellow just twenty years old came to the lumber-yard and asked for work. He said he had not had a bite all day Sunday, and had had no breakfast that day. As it usually happens at this season of the year, our business is slackening up, and the foreman of the yard told him he did not know how we could use any more help just then. But he gave him a bite out of his own dinner-pail; and although I remembered former experiences I gave him a hoe and set him at work in the cornfield. Well, it was one of my "happy surprises" to see him get down and do about as much work in an hour as the usual run of help will do in two hours. The field had been cultivated, but ragweeds had started up in and around the hills. Of course, there were not weeds in every hill; but he just flew, as it seemed, from one weedy hill to the next one—got down on his hands and knees, got out every weed, smoothed the dirt back with a dextrous flourish of his fingers, and then really jumped and ran to the next weedy hill. When I saw how he was "panning out" I told Mrs. Root about it and she hurried up a pretty good lunch of nourishing food, remarking at the same time that he certainly could not keep up at that "gait" for the whole day. But, to my surprise and astonishment, he did; and just before the whistle blew (with the help of another good man) the cornfield was finished. One reason why I was anxious about it was that the corn had been cultivated for the last time, and we were in a hurry to get in some sweet-clover seed. This was put in

with a drill (between the rows) with a weeder tool to work the seed into the soil after the seed had been dropped on the surface. Although our business is slackening up at this season of the year (July 20), I told Mrs. Root I was going to see that that boy had a job. By the way, he seems to be a foreigner, and speaks our language very imperfectly, and I have before noticed that some of these foreigners, before they have learned the Yankee trick of "soldiering," are a refreshing example of what a man can do in the way of getting along with his work if he is really anxious to *have a job*.

SOWING SWEET CLOVER BETWEEN ROWS OF CORN AT THE LAST CULTIVATION.

It is now August 20, just one month since the sweet-clover seed was sown, and it is up and growing as only sweet clover can grow. We put on about 15 lbs. per acre, and I should judge there was twice the quantity needed, and perhaps more than that. As the seed was put through the new scarifying machine, probably almost every seed germinated. The plants are now six inches tall. The abundant rains seem to have just suited the sweet clover. The corn, too, has made a most astonishing growth. Some of the great ears are lopping over already, and it looks very much just now as if sweet clover does not hurt the cornfield as do ragweeds and other foul weeds. Before the sweet clover gets up so as to take the fertility and moisture from the corn, the corn will probably be beyond injury from the clover. Of course, the abundant rains probably have had much to do with the tremendous growth of both corn and clover.

Still later.—It is now Sept. 10. The clover is a foot high, and much of the corn would do to cut. By selecting ears of early maturity for several years I have a strain of early maturity; and I believe we have about the best *whole field* of corn I saw on my trip to Columbus and back.

SWEET CLOVER FOR FEEDING STOCK; A COMPARISON WITH CORN FODDER WHEN FED TO MILCH COWS.

I notice quite a number of our agricultural periodicals are rather slow to give sweet clover credit, for some of them go so far as to say that farm stock will not eat it except when they can get nothing else, etc. Below is something which we clip from the *Beekeepers' Review* for Septem-

ber; and inasmuch as quite a number of similar reports are now coming to the front it seems fit that some of these periodicals should keep a little better posted and up to date.

I have had some personal experience with sweet clover this fall, and I now know that stock will eat and relish it. One of my neighbors told me that his horse would now leave a mess of oats any time for sweet clover, although at first refusing it. This neighbor is a feed-dealer, so naturally his horse would be well fed. Our Jersey cow at first refused it, but gradually began to eat it; and when I was about out of it I found she preferred it to corn fodder; and I also discovered that when fed corn fodder after being on sweet-clover hay she dropped about three quarts per day off her milk. Just think what this means—6 pounds per day for 300 days, the average milking period—equals 1800 pounds of milk at 6 cents per quart, \$108 more per year per cow; or at \$1.75 per 100, which is what farmers get in shipping to the city, it would amount to \$63.00; and this astonishing amount is just the difference in favor of sweet-clover hay over corn fodder and other feeds, grains being the same, and sweet-clover hay being the equal, ton for ton, of wheat bran in feeding value according to U. S. Department of Agriculture analysis; and while growing sweet clover we are greatly enriching our land.

Milford, Mich. EARL F. TOWNSEND.

SQUASH-BUGS, AND BLACK-KNOT ON CHERRY AND PLUM TREES.

Mr. Root—:—I see that you have quite a lot to say about squash-bugs. I have something that will drive all the squash-bugs out of Ohio in one season. Take pine sawdust when your plants just get out of the ground, and put it 1½ inches deep under the plants; then when they are six or eight inches high put on some more sawdust. This is for squash, cucumbers, pumpkins, and watermelons. I have another recipe for black-knot on tame cherry and plum trees. Take the soot from your chimneys and put one quart around each tree at the ground. That destroys the germ that causes black-knot, and it will never fail.

I am an orchardist, and the two recipes are free, so please pass them along.

La Grange, Me., Nov. 7.

E. A. DAY.

I presume that in the above the odor of the pine sawdust is what repels the bugs. I find they are in the habit of boring down around the stalk and roots of the vines. In fact, they crawl down in the dirt, and hide. Very likely this pine sawdust, with its strong odor of turpentine, would be sufficient to repel them. If I remember right, some other writer has recommended kerosene worked into the sawdust, being careful, of course, not to get it so strong as to kill the vines.

HAND CULTIVATORS, STRIPED BUGS.

I am nearly 70 years old, but I am a good gardener. I know how to make stuff grow by working the ground often and using shallow cultivation. I have about two-thirds of an acre in my garden, and all tended by hand, with my wheel plow and hoe. I use the Excelsior double wheel, about 14 inches between wheels. I use two plows or two weeders, as I wish. One can do more than double the work with them than with a single wheel, and no harder work. My garden is fine, and full of stuff—one of the finest gardens in all this county. The dasheen is growing finely—nearly 2 feet high. The rainbow corn is nearly 2 feet high, and is showing up finely.

I had a hard fight with the yellow striped cucumber bugs. I had to replant. I finally got the upper hand of them. I had (like you) to do a little Sunday work with them, but under compulsion. I do not think I sinned. If I had let the plants go until Monday they would have been about all killed. Now I have some nice vines. There were more bugs this season than I ever saw before in one season.

We (that means my better half and I) do enjoy your Home department. I am so glad temperance is advancing so fast.

Delta, Ohio.

T. W. CONNELL.

HEALTH NOTES

STILL ANOTHER IMITATION OF ELECTROPOISE.

It is really a shame and disgrace to humanity to think that a senseless toy that has no more virtue than a horseshoe nailed over the door should not only induce thousands to invest their hard earnings, but should be imitated again and again to "pick the pockets" of the unwary. Just now we have a circular before us that reads as follows:

ATTENTION! IT TREATS DISEASE WITH OXYGEN

You may now borrow an oxybon, use it thirty days, and treat your ailment in your own home. This may seem remarkable to you, but, nevertheless, it is a fact. If you have failed to find relief from any other method of treatment, then all we ask is that you give us an opportunity to demonstrate the worth of our invention by trying it for 30 days. If you are suffering with any ailment, don't hesitate. Write us now. It may be the turning-point in your life from sickness to health. It treats disease with

oxygen. No medicine, no belt, no battery, no electricity!

Some of you may wonder how it is that they get money by sending their traps out on trial. The explanation is this; and it applies to a great part of the remedies found in the drugstore. After reading their printed matter, and especially testimonials, many people (and I might also say most people) get the impression that there really must be some wonderful invention or discovery about the thing; and under the influence of the imagination, and nothing else, they hand over their good money. While the original electropoise had only one wire, this thing has two. You drop it into some ice-cold water. Then you clasp a wire to each ankle, and lie down and take a rest. Is it not a little funny that people do not catch on to the idea that lying down and

taking a rest when fatigued and worn out will do a lot of good *without* any electro-poise?

WHISKY AND BRANDY NOT MEDICINES.

The following, from the *Ohio Messenger* for September, is important:

PHARMACOPOEIA DROPS LIQUOR.

The National Pharmacopoeia Committee, composed of fifty-one of the leading physicians of the country, has cut whisky and brandy from the new edition of the United States Pharmacopoeia.

This means that whisky and brandy have been declared officially to be neither drug nor medicine. The new edition of the pharmacopoeia will be issued about January 1, 1916, and after that time brandy and whisky cannot legally be sold by druggists as medicine.

It will then be necessary for the druggist to meet the local requirements—i. e., take out a saloon license if he wishes to sell "nips" behind the counter.

This decision as given above is far more reaching than I supposed. If it is really true that no druggist can in the future sell intoxicating liquors without taking out a saloon license, we can praise God for another advance in temperance legislation.

"ROBBING SICK PEOPLE;" HOG-CHOLERA CURES.

I hold in my hand a pamphlet of 8 pages sent out by the Agricultural Experiment Station, Iowa State College of Agriculture and Mechanic Arts, Ames, Iowa. This pamphlet gives in detail the results of experiments with six so-called hog-cholera cures. From a summary at the close of this bulletin I extract the following:

All tests above indicate that none of the products entering into the tests protected hogs against attacks of hog cholera except hog-cholera serum prepared according to the general plan worked out and recommended by the Bureau of Animal Industry of the U. S. Department of Agriculture.

I have several times of late seen notices in agricultural papers that the hog-cholera cures, like much of our advertised patent medicines for the human family, were worthless, or worse than worthless, because they prevent the poor suffering farmer from availing himself of the remedies advertised by the U. S. Department of Agriculture. There is a big moral here—do not touch or listen to anybody recommending or selling any cure for domestic animals unless it has the indorsement of the experiment station belonging to your own state or the indorsement of the Department of Agriculture at Washington. I grant that sometimes the venders of these medicines are honest, but they are mistaken. Our several stations have competent men to advise and safely direct in all these troubles that afflict the farmer.

In the experiments detailed in the bulletin mentioned above, all of the pigs died when treated with the six different remedies, and *not one* died when treated by the authorized hog-cholera serum.

SPECIAL NOTICES

BY A. I. ROOT

"THE STORY OF ART SMITH."

The above is the title of a paper-bound pamphlet of 94 pages. It was sent me by my grandson feeling sure I would be interested in it because of the fact that I was with the Wright brothers when they made their first flight that succeeded in bringing the machine back to the place of starting. The book interested me for two reasons: First, because it was all about experiments with flying-machines; second, because the boy started out when he was only 15 years old—nearly the same age that I was when I started out giving "lectures(?)" on chemistry and electricity. There is still *another* reason why the book took a mighty hold on me. This boy, Art Smith, it seems to me, had more mishaps and discouragements and failures than I ever heard of falling to a single human being; and yet he is now, at the age of only 21, turning somersault after somersault away up above the clouds, leaving a trail of smoke by day and a trail of fire by night, to show the path that his machine actually made through the sky.

I think that when I first opened the book I was standing up; and in a little while I got off by myself where nobody would interrupt me. As it came dinnertime I felt I could not stop for dinner nor anything else; and I am afraid I was unfeeling enough to get off with the book where Mrs. Root could not ask *why* (for once in the world) I was not ready for dinner. I doubt if I ever before got hold of any book that held my attention as did that one. Here is a brief extract from page 4:

"Of course, there are only a few of us now who feel at home in the air—really at home, knowing the air and its ways, so that we can roll about up among the clouds like a kitten in a basket. Because we are pioneers in the air, with difficulties and dangers to overcome, it is interesting to know how we do it, and what it feels like.

"The story of how I learned to do it is doubly interesting to any one who is trying to do anything difficult in the world, because I think no one can have a harder time realizing his ambition than I had in learning to fly."

In the middle of the book we read of the way his machine turned over sidewise and was going crashing into the ground with the heavy engine, etc., and when within twenty feet of the earth it suddenly righted and skimmed off like a bird, unharmed. When his good mother (a *praying* mother, by the way) saw that death to her venturesome son seemed *inevitable*, she fell on her knees and said, "O God, save my boy!" and, *while* she was praying, the machine righted itself in a second of time, and her boy was saved. Below is the finishing paragraph of the book:

"The world is carried forward by man's great dreams. The greatest dream of all is the conquest of the air. What it will mean to human life we know no more than Watt knew when he watched the lid of the kettle and dreamed of the first steam-engine. Aerial navigation will mean, as the steam-engine did, more than we can imagine now.

"Big men are working on it. Big men will some day conquer all the difficulties which we are fighting.

"We are only pioneers, but we are pioneers with a great idea. Some time in future centuries the whole world will be revolutionized by that idea. Then it will know the value of the hope and the thrill we feel as our aeroplanes rise from the earth, pass through the clouds, and fly high in the clear upper air."

The price is 25 cents postpaid; but every one who sends us \$1.00 for GLEANINGS may have the book for 15 cents. I am well aware that some of my good friends may criticize me for encouraging what has cost so many lives already; but my reply is that the book will help to *save* life; and it will also encourage patience and perseverance among the young inventors now growing up more than any other book that I have ever read or heard of. The book is not fiction, because every event mentioned occurred out in the open air in the plain sight of hundreds and thousands gathered to see Art Smith fly—the boy who was born and brought up in Ft. Wayne, Ind.

gleanings in Bee Culture

This is Pacific Coast Year

The eyes of the nation are turned toward the empire of the western seaboard with its two expositions and its unparalleled opportunities for travel.

Similarly, the beekeepers of the West, producers of an important part of its wealth, are turning to the two branches of The A. I. Root Company for their supplies.

Californians and producers in other Pacific Coast states who are in the market for supplies are asked to write for catalogs and prices.

Full line of Root goods are carried at both offices. Do not forget those power extractors. Order your cases and cans early.

While enjoying the splendors of the Panama-California exposition at San Diego this year, remember to inspect The A. I. Root Company's exhibit in the Varied Industries Building. Our concession stands at the right of the east entrance where you can't miss it. It's interesting and comprehensive. See demonstrations of the new friction-drive power extractors. We have another exhibit in the Palace of Food Products at the Panama-Pacific exposition, San Francisco.

Honey-crop Reports and Prices

EVIDENCE is accumulating showing that the crop of clover and other northern white honeys is much larger this year than last. This is not saying that clover was not an entire failure in some parts of the North. The fall flow has been reported as being remarkably heavy in a large portion of the North. In other respects the western crop is about the same as reported in former issues.

Prices are running anywhere from 15 to 20 per cent lower than last year on all grades of extracted. There is probably more comb honey than was expected earlier in the season. It is now being unloaded, and there is every indication that it will bring good prices.

Excessive and Late Swarming this Fall; Clover Prospects for Next Season

WE have had a large number of reports this year of late swarming—of how the bees rushed out of their hives without even building queen-cells. One of our subscribers, whose letter we may publish, tells of getting 175 swarms from 70 colonies, spring count. There have been other reports of a similar nature. Many of the swarms came out without knowing where to go—that is, they left hurriedly without sending out scouts. Some swarms leave no queen-cells. One beekeeper packed his bees for winter, and then had a swarm come from the winter case. See what O. J. Jones and Dr. Miller have to say, p. 817.

It is evident that the cool rainy weather over a large part of eastern and northern United States during the spring and late summer has stimulated everything to a vigorous growth. Bees are working well on alsike, second-growth red clover, heartsease, Spanish needle, asters, buckwheat, and goldenrod, as they have never done before at this time of the year.

In all of our more than thirty years' experience in connection with this journal we do not remember a time when there were so many reports of such heavy flows in the fall. Everything seems to be raining down

honey except, possibly, white clover, which is still in bloom.

Beekeepers in the clover districts particularly seem to be jubilant over the prospects for next season, for never was there such a mass of young white clover as seems to show up everywhere. If we do not get a drouth this fall or next spring, and we must not forget there are two *ifs* in the way, we shall have a record-breaking clover season next year.

How to Sell Comb Honey under the Federal Net-weight Law and Get Pay for Every Ounce

AN old correspondent, who is also a large producer of honey, has written us for information. He says if he is compelled, under the federal law, to mark the minimum net weight on each individual section, and sell on that basis, there will necessarily be a surplussage of anywhere from $\frac{1}{8}$ to $\frac{3}{4}$ ounce of honey that he will lose on every section of his entire crop. He estimates that, if he sells his comb honey on the basis of actual minimum net weight per section, and not their actual aggregate net weight per case, he will lose \$100 on one shipment alone.

Our correspondent is laboring under a wrong impression. He, like all other producers, if he uses separators or fences, will probably have three grades, one class calling for a minimum weight per section of 12 ounces, another of 11, and another of ten. We could sell a case of 24 sections of the 12-ounce class and get no more than 12 times 24 ounces, or 18 lbs.; but that is not necessary. For his information, and for the information of every one else, we may say that the federal net-weight law, while it does require the marking of the individual packages or sections, it does not compel *selling* on that basis. It is permissible to mark the minimum weight on the carton inclosing a section. The purpose of the law is to give the consumer a chance to know approximately how much actual weight he is paying for in the package.

We find in practical experience that the

average 24-pound case of sections marked "Not less than 12 ounces net" per section will run anywhere from 12 to 18 ounces more than the actual minimum weight of 18 pounds. The producer is permitted to sell a careful of sections at its actual weight exclusive of the case and the wood around the combs; but the weight should be marked on the end of the case. On that basis *he gets pay for every ounce of honey he sells.*

The retailer, however, will probably sell the sections at so much a piece. One customer will get just exactly 12 ounces, while another will get 12½, and still another nearly 13 ounces; but the dealer, in order to protect himself, will mark the price of his sections high enough to cover the variation. But there is nothing to prevent his selling each individual section at its actual weight. He will then be obliged to stop and figure up the price as he would that of a chunk of meat or a plate of butter that is dipped out of a crock. On a busy day this is impracticable. In nine cases out of ten he will sell by the piece; and right here the federal net-weight law, instead of being a hardship, is welcomed by the dealer and the buyer; and it ought to be welcomed by every honest producer, because he knows that his customer knows just how much he is paying for.

But there is another way by which our correspondent can protect himself, and it is used by a large number of producers and wholesalers; and that is, to sell the honey at so much per case. For instance, a 24-pound case of sections marked "minimum of 12 ounces" will bring, we will say, \$2.75 per case, or \$3.00, whatever figure he can get. A case of 11-ounce sections will bring correspondingly less; or, if he chooses, there is nothing to prevent him from selling all his comb honey at so much per case, whether it is 10, 11, or 12 ounces per section. It is the usual practice to sell the 12-ounce as "fancy," the 11 ounce as "No. 1," and the 10 ounce as "choice," each bringing a corresponding price.

As time goes on, we believe the public will appreciate the fairness of the federal net-weight law, because it will operate to the advantage of the honest producer and dealer alike. The only fellow it hits and hurts is the producer or dealer who was in the habit of selling irregular sections of all kinds of weight, and light sections at the price of a regular and first-class graded product. As it is not practicable nor necessary to mark the *actual* weight on every individual section, he is compelled to mark the minimum, and to grade by weight.

What is it—Nosema Apis, Bee Paralysis, or What?

DURING the last two months we have had complaints from a good many beekeepers, particularly in the Northwest and extreme Northwest, to the effect that a peculiar malady, something like bee paralysis, was carrying off adult bees by the thousands. They have seen traces of it other seasons, but this year it is particularly bad, ruining entire apiaries in some localities.

In some places, particularly in and about Portland, Oregon, the disease has disappeared. In other cases it seems to be as virulent as ever. Many of the symptoms are similar to those of bee paralysis, and yet just enough unlike it to make one think it is something else. A description of the malady, whatever it is, appears to tally very closely with the disease known as "nosema apis," or Isle of Wight disease of Great Britain.

It has been found this season in parts of Wisconsin, Minnesota, and clear along down the Mississippi Valley; but it seems to be particularly severe in and about Seattle, Washington. One of our subscribers, Mr. M. Y. Calcutt, writes:

I am enclosing you herewith a clipping from the *Seattle Times*. You will see what Prof. Trevor Kincaid has to say regarding a disease that has scourged the bees.

On the 28th of July I noticed the bees were hopping about in the grass, and were to be found in bunches on the ground with their heads together as if starving. On examining the hive I found they had plenty of stores. I then examined yard No. 2, and found like conditions existed there. I then started out to other yards, and found the same condition in all hives in this part of the county. Bee men from other parts were soon calling on me to see if I could give them some advice as to what was the matter with their bees, and the remedy to be applied. I was sorry indeed that I could do nothing for them but to advise shaking and feeding up for new broods, as all or nearly all the brood was dead or dying. The disease seems to attack the larvæ from three days old to that about the time the larva is to burst its cocoon. The cell-cappings are the same as American foul-brood cappings. Prof. Kincaid tells me that the bees' heads are full of spores, and he is convinced the disease is communicated through the flowers, which must be so, judging from the rapidity with which it has spread. I am inclined to think he underestimates the number of bees destroyed since July 28. I am fully convinced, from examination of all the hives here, and those in my yards, that fully 80 per cent of the bees have died since that date. Two-story hives do not to-day contain one good frame of bees. It looks at this writing as if no bees will be left. If shaking and feeding will not stop it, then all the bees are doomed; and, as Prof. K. says, the fruit crop for 1916 will be small indeed. I am sending samples to Washington, D. C.

Seattle, Wash., Aug. 28.

M. Y. CALCUTT.

The newspaper clipping referred to is as follows:

HONEYBEES OF NORTHWEST ARE MEETING DEATH;
STRANGE MALADY, THAT IS ATTACKING NOTED
ZOOLOGIST'S HIVES, IS WIPING OUT COLONIES IN
SEATTLE.

Jeopardizing the entire 1916 fruit crop of the Pacific Northwest, a mysterious scourge, so far baffling to specialists, has already decimated fully fifty per cent of the bees in this state, and is threatening, unless some remedy is found, to destroy completely the bee industry in Washington.

Professor Trevor Kincaid, zoologist of the University of Washington, and one of the best-informed entomologists in the United States, has lost more than half of his own bees, and has received a number of letters from all over the state informing him that the honey-making insects are dying by the thousands.

He believes that practically half of the honey-producers in the state are already dead; and as these insects are largely instrumental in pollinating the fruit-trees, the growers will face a serious problem next year if the ravages of the mysterious disease are not halted.

"I thought at first that the disease was bee paralysis," said Professor Kincaid; "but further investigation has convinced me that it is a complaint that is analogous to malaria or sleeping sickness in the human family. I have expectations of being able to work out a cure. It may be that the disease is being spread by bumble-bees.

"Ordinarily a bee is a fierce fighter, and is well qualified to take care of itself; but since the disease has appeared among them they have become easy prey to their enemies. Yellow-jacket wasps, which ordinarily will not tackle a bee, are hovering around the hives in hundreds. They attack the bees, and the latter are unable to retaliate.

"I have been unable to find any information on this disease in the text-books, and have communicated with the Department of Agriculture. The entire Northwest is involved: and unless the disease is eradicated it is going to have a very serious effect on the fruit crop next year. This year's crop will not be affected, as most of the trees have either borne fruit or are in bud."

No one else has before mentioned that the malady has any effect on the brood. In the Seattle case we should assume that there was such a rapid decimation of bees that the brood, by reason of neglect, simply dies. It is our opinion, therefore, that, so far as the brood is concerned, it is only a case of neglected or starved brood.

Every year, for the last 25 or 30 years at least, we have seen dead and dying bees in the fields; but the number was so small as to attract very little attention. Practically every beekeeper, if he has any considerable number of colonies, has noticed the same thing; but it was not until this year that it has broken out in such a virulent form. The presumption is that the peculiar season—cold, rainy, and wet—has had something to do with it. If it is nosema apis, it seems to like a humid atmosphere, such as is found in Great Britain and in Oregon and Washington of our own country. We have never heard of nosema apis in this country, unless it was what we call bee paralysis, until this year.

We talked with Dr. E. F. Phillips, of the Department of Agriculture, about the general aspects of this malady. We asked him if he knew anything about it. "Only the symptoms, which are by no means uniform, and nothing about the cause and cure," he replied. The foul-brood inspectors of Central United States have seen much of it.

It may be reasonably assumed that Dr. Phillips will do all he can to get all the reliable information he can concerning this new disease. Possibly it is not a disease at all, but a malady due to climatic conditions.

=====

Some New Uses of Honey in the Home

WE are rather proud of the magnificent way in which our subscribers have responded in furnishing recipes for using honey for this special number on the use of honey in cooking. At one time it looked as though we should have to make this number about twice its usual size in order to use all of the good recipes that were sent us. However, by doing a little crowding we have succeeded in getting them in.

To the best of our knowledge none of these recipes, except as otherwise noted, have ever appeared in any other publication. Of course, some of them might have been copied from some other papers, but most of them, we believe, are original with the persons who sent them in.

It is, perhaps, proper at this point to remark that we have tested quite a number of these recipes—not all of them, to be sure, for that would be a task indeed. Perhaps it would be a little nearer the truth to say we have tested them "by proxy," the proxies being Mrs. E. R. Root, Mrs. H. H. Root, Mrs. J. T. Calvert, Mrs. Neal Kellogg, Mrs. L. W. Boyden, and Ruth Boyden. Some of the results of their work are shown on our cover and also on the interior pages of this issue. One or two recipes were voted a failure; but in the majority of instances every one who had the privilege of eating some of the cakes, pies, or cookies in question pronounced them excellent.

Honey certainly makes a great difference in a recipe, provided the recipe in question is well balanced and all proportions right. As we have mentioned many times before, the mere substitution of honey for sugar seldom results in success, for honey and sugar do not have the same physical characteristics. However, with distinctly pleasing results, honey may often be used instead of molasses or the so-called "corn syrup," without further change in the recipe.

HONEY HOT OR COLD.

We have noticed in our own home, and in the homes of many others of our acquaintances, that honey is not apt to be used as much in extremely hot weather. There are, perhaps, several reasons for this, perhaps the most important being that honey when it is warm is much thinner and a little stronger in flavor. Honey that is cold and thick certainly tastes better. Mr. Holtermann points this out in his note on page 799.

For the same reason, not many people care to eat honey on hot breakfast foods. Of course, there are exceptions; but the average person, we will say, if he uses honey at all on breakfast foods, prefer it on a cold cereal like cornflakes, etc. To take advantage of this fact, we should not be too strenuous in insisting that honey *never* be placed in a refrigerator. It should not be stored there indefinitely, that is true; but it is greatly improved if it can be placed in the ice-box for a few hours just before it is served on the table. Even hot biscuits taste better if the honey is thick and cold.

HONEY FOR BROWNING PANCAKES.

It has been suggested before, but is well worth repeating here, that a little honey stirred in with pancake batter serves an excellent purpose in permitting the cakes to be baked to a rich golden brown without danger of burning. It is not necessary to use enough honey to sweeten the cakes. Every one likes griddle-cakes better if they have the proper color, instead of being pale and white.

BUCKWHEAT HONEY FOR VINEGAR.

One of our subscribers, Mr. Chas. A. Johnson, of Battle Creek, Mich., commenting on the fact that honey vinegar is so often pale or water-white, points out that if buckwheat honey is used the color is exactly the same as that of vinegar made from apple cider.

HONEY USED IN LATHERING THE FACE PREPARATORY TO SHAVING.

The beneficial effect of honey on the skin has long been known. There have been many preparations using honey in the various creams and ointments for rubbing on the hands and face. Men who shave themselves may be surprised to learn that lather containing some honey is delightfully cool and creamy compared to the thin and quick-drying lather so often produced, even from the best of shaving-soap (advertisements of the soap in question to the contrary). We have incorporated the honey in the soap, making a very satisfactory paste or cream; but the most convenient way to use honey

when shaving is to put a small amount of honey on the end of the brush and then use whatever soap is desired, in the regular way. Put three or four drops on the end of your *wet* brush, and then use your favorite soap. You will find at once that the advertiser's "dream" has come true. The honey is soothing to the skin, and the lather remains smooth, moist, and creamy, even if it takes fifteen minutes to shave.

HONEY AS A CURE-ALL.

Soon after the announcement of this special number we received quite a good many so-called cures for such serious troubles as cancer, erysipelas, etc. We have taken the position that, before publishing the recipes for these salves, ointments, and lotions we should have the signature of at least one reputable physician with a report of his experience using the cure in question. Such salves might not do any harm, but we seriously doubt whether they would be of any benefit whatever.

A simple remedy for a cough, which we have found of especial value for small children, is a mixture of honey and common vaseline. Equal parts may be stirred together, forming a paste; and as much as a spoonful of this may be given at a time without danger of disturbing the stomach. Ordinarily half a spoonful is enough. All children like it.

The Troubles of an Editor; Quality versus Beauty only

IN our issue for Sept. 1, page 699, we have an editorial headed "Can Good Queens be Raised and Sold for 50 cts.?" We went on to state that there were times in the season, especially at the close of it, when the breeder could afford to sell his surplusage of queens at 50 cts. apiece in order to reduce stock; but we added that we did not believe that, as a regular proposition, week in and week out, he could afford to do so through the entire season, and we still think so. Two of our standard advertisers, good men, and who furnish good stock, seem to think we had them specially in mind when, as a matter of fact, we were not referring to any one. At all events, they put the shoe on just the same, and, of course, think we have been unfair.

In looking at the advertisement of one of them (the one who makes the loudest holler) we notice that he has a "surplus of young queens," heading his advertisement with the words "Special Offer."

Our editorial, as will be seen, was not criticising queen-breeders who are disposing of "surplus stock" or making "special

offers." We simply raised the question as to whether one can maintain the price of 50 cts. all through the season.

Still another party—a well-known queen-breeder of first-class golden stock, and one of the best-known men in our ranks—complains because we have given it as our opinion that many of the extra golden-yellow bees are not as good as the leather-colored stock. It seems we wrote this party, congratulating him on the excellence of his stock, because it was resistant to European foul brood. Immediately he came back at us, saying we were inconsistent in praising the thing we had condemned. We tried to explain to him that we could not afford to smother our honest opinions, right or wrong, simply because of the few extra dollars we might make in our advertising columns. Moreover, we have never declared that *all* goldens are inferior to the leather-colored stock.

In almost the same mail came a letter from a breeder of extra-yellow bees, commending us for the fearless stand we had taken in our various editorials, and saying that he expects to take GLEANINGS for the rest of his life. *He*, evidently, does not consider that we are condemning *all* goldens. The fact is, if a breeder sells good stock, golden or leather-colored, the trade will discover it and patronize him. This is shown by the fact that some breeders have advertised with us for years.

To make our stand clear, it may be well to reiterate that, although we have spoken disparagingly at times of *some* goldens, we have not condemned *all*. That is only another way of saying there are some goldens that are not only beautiful, but good workers, and some goldens that seem to resist European foul brood as readily as leather-colored Italians, and possibly better. We would gladly give the names of some of these breeders who are furnishing this kind of stock; but if we did so, this poor editor would have more trouble on his hands from the other fellow whose name was conspicuous by its absence.

If the reader cares to look over our editorials he will see that we have frequently condemned the policy of advertising five-banded bees, and furnishing only three and four banded stock. While there is such a thing as a "five-banded" or "yellow-to-the-tip" bee, it is almost impossible to make *all* the bees of a queen show up like that. The effort on the part of some to get the "yellow all over" has naturally led them to sacrifice efficiency and longevity for color. As a natural result, many of the extra-yellow bees have been markedly in-

ferior to bees bred for business, color being maintained only as a secondary consideration.

It is the *policy of breeding for one thing only, and that thing not a business qualification in our bees, that we have condemned; and we still stand on the same platform. We do not condemn beautiful bees that are also good workers, nor the breeders of them.* Some of these people have developed some very fine stock, including our advertiser who complains.

=====

Dr. E. F. Phillips and the Editor of Gleanings at the Home of Dr. C. C. Miller, of Marengo, Ill.

DR. PHILLIPS and ourself had the pleasure of paying a very short visit at the home of Dr. C. C. Miller, on the 6th of September last. We were on our way to the field meet at Hamilton, Ill., the home of the Dadants, and stopped off one day.

There may be other beekeepers who produce honey in sections who harvest larger crops. There certainly are many such. There may be others who can produce an equal quality and possibly better; but practically all of them are using some of the methods, at least, of the sage of Marengo. Dr. Miller, in the opinion of Dr. Phillips, has evolved a system of comb-honey production that is very nearly perfect. He has no trouble about getting bees in comb-honey supers, and very little difficulty in controlling swarming. He will secure a crop of comb honey when other beekeepers get almost nothing.

The secret of his success lies in securing *a large force of bees in time for the harvest.* Said Dr. Phillips, "Too much emphasis cannot be placed on that point." His other secret is *conserving the force of bees after he gets it.* "Secret," did we say? Dr. Miller has no secrets and never did have; but he does have tricks of the trade that every producer of comb honey in the United States should know. Thousands of beekeepers who have been running for section honey have given it up in disgust. Something is wrong. They complain that they cannot get the bees into the supers; that their honey-flows are too short and intermittent; and that the swarming problem is too much for them. But Dr. Miller handles all of these problems at the ripe old age of 84, with no other help than that of his sister-in-law. In fact, he has been doing it year after year for thirty years.

At the time of our visit there was such a roar of bees about his yard that it looked as if there was a big swarm in the air—in

fact, several of them. Nay, rather it looked exactly like a wholesale case of robbing; but it was neither. An inspection of the apiary showed that large streams of bees were going into every one of his hives. We never saw such a furor of bees before in so small a yard—92 colonies, spring count. While the apiary was small, there was an immense force of bees in every hive, and on every one of them there were anywhere from two to five comb-honey supers well on to completion. The honey the bees were getting at the time was apparently from heartsease. While Dr. Miller had taken off a small crop of fine clover honey he feared that what was still in the hives might be flavored with heartsease; and heartsease does not improve a fine clover.

We had a great curiosity to see what the bees were working on. There were acres and acres of white clover in bloom. Was it not possible the bees were working on that? But there did not seem to be many bees on these blossoms; so we took a stroll all by ourself, leaving the two doctors—the M. D. and the Ph.D., to discuss the problems while we were gone. We went over the hills, through patches of woods, through barbed-wire fences galore; through cornfields; got lost, but finally got back, after a wide detour, to the home of the Millers. The women feared we were lost, and began to think seriously of sending some one after us; but, like the proverbial penny of uncertain quality, we turned up.

They were all eager to know what we had found—that is, what the bees were working on. We had to confess we did not know. There was occasionally a bee on the clover—perhaps one to every radius of 100 feet. There were quite a number of bees on sweet clover, and occasionally a bee on the heartsease—perhaps one for every radius of ten feet. Heartsease—there was lots of it just coming into bloom. It grows as a weed in the cornfields, and corn is grown extensively about the Miller apiary. While the heartsease was only just coming into bloom with only a few bees on it, it did not seem possible that such a great roar in the yard could have come from that source, and yet there was an odor of fall honey about the hives. It might have been from the asters; but the asters were negligible, for but few of them were in sight. There was some Spanish needle, but there were no bees working on it. There was considerable sweet clover, but apparently not enough to make such a showing. What, therefore, could the bees be working on? Dr. Miller began to figure—one bee for every radius of ten feet on the heartsease,

and there were many tens and tens of acres of it in the cornfields that were numerous. The bees on the white clover, on the sweet clover, and the heartsease, if they were scattered over a radius as large as $1\frac{1}{2}$ or 2 miles, might, according to Dr. Miller's figures, account for that tremendous roar of bees.

Although Dr. Miller is in the habit of taking a midday nap, he was bright and alert all the time we were there from 11 o'clock until 7 at night. We could not imagine any kid beekeeper more enthusiastic than this veteran of 84 summers. Of course, Dr. Phillips and ourself gave him some hard question. Always modest, he frequently said, "I don't know."

A striking feature of Dr. Miller's make-up is his modesty. He does not seem to know that he has discovered methods that make for success. He claims no originality, and yet he certainly *is original* in making up a combination of methods that is unique in the production of comb honey.

By the way, we forgot to mention one thing, and that is Dr. Miller's strain of leather-colored Italians. While his methods and his locality have done much to contribute to his success, careful selection of queens of his own breeding has been an important factor. No mistake about it, they are hustlers, every one of them. Those queens ought to be worth from \$10 to \$25. With those queens Dr. Miller is successfully combating European foul brood. They are not much inclined to swarm if his methods are used, and they certainly get there with the honey.

We do not know that Dr. Miller has any queens for sale; but he said, "At our ages" (referring to himself and his family), "we have more bees than we can handle. We may be compelled to cut the force down."

Dr. Miller does not know that we are giving him a free advertisement; but we suggest that some of the queen-breeders of the country get some of his stock and cross it with their own before it is too late and the genial smile of the owner is forever gone so far as this world is concerned.

But, to return. When we left Dr. Miller at the electric station to go back to Chicago, and from there on to Hamilton, there was the same smile that doesn't come off, but a look—a far-away look—as if he thought that possibly he might not see us again on this side of the river that separates us from the world beyond. We hope we shall see him every year till he is 100. If careful living will do it, he will reach the mark. Indeed, he looks as young as he did ten years ago.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

GRACE ALLEN, p. 702, sometimes darkness is an advantage when introducing, since there are then no robbers about to make the bees kill the queen.

THE OUTLAW, p. 545, has surely struck on a good thing in having full frames instead of sections for cafeterias. As the honey is to be cut up into portions in either case, what advantage is there in the section?

G. M. DOOLITTLE, many thanks for telling us, p. 750, what perhaps I ought to have known, but really didn't know, that it made all the difference whether a full or an empty comb was used in spreading brood. After all, if the bees already have all the brood they can cover, will spreading be a good thing?

J. E. CRANE, you say, p. 748, that sections with bottom starter were no better attached at the bottom than those without. Does that mean that the bees gnawed down the bottom starter, that they build down well without it, or what? When I used no bottom starter many sections were not built down at all, while with them there is no failure. What makes the difference?

FOOLED again! On p. 745 I said that, although bloom was abundant, I gave up hope of anything to speak of from it. Scarcely had I written that when the bees started on a craze for gathering I never saw excelled. Clover, aster (other years aster yields nothing here), heartsease, and I don't know what all, seem running over with nectar. You never know what bees will do next. [See reference to this subject in editorials, this issue.—Ed.]

A CORRESPONDENT refers to page 553 of A B C and X Y Z, where "a frame of unsealed larvæ" is recommended to attract the bees of a swarm, and wants to know if sealed wouldn't do as well. Generally, when you take from a hive a frame containing unsealed larvæ, you will have sealed as well, and I suppose nothing could be better than a frame having all kinds. But if it is a choice between a frame having only unsealed and another having only sealed, all my observation tends toward the belief that bees have a stronger attachment to the sealed. [A. I. Root, as you will remember, used to teach and preach that a swarm favors unsealed rather than sealed brood—or, rather, he always gave directions that, in order to hold the swarm in its hive, we

should give a frame of unsealed brood. Who is right?—Ed.]

MR. EDITOR, you ask, p. 746, whether my treatment of European foul brood is not the basis of the Alexander treatment. Let me say with all the emphasis I can that I never wanted it understood that my treatment was anything but the Alexander treatment, the big principle of the whole thing being that cessation of brood-rearing would allow the bees to clean up. I merely shortened the time of treatment, and that by a stupid blunder—a change that I am sure Mr. Alexander would have made if he had lived long enough. [Yes, we know very well that you do not claim originality except in the matter of time; but we merely asked the question in order that the public, who, perhaps, had forgotten, might know the precise situation.—Ed.]

A YOUNG queen is far more profitable than an old one, because she will lay till late in fall, while "an old queen that has exhausted herself in the early part of the season will usually stop laying when the main honey-flow ceases," page 699. True as preaching. Yet the evils depicted as resulting from that old queen being left don't happen with me. I suspect it's because the queen that has exhausted herself is always superseded by the bees. At any rate I don't believe it pays for me to meddle with the superseding business unless there's some other reason for it than old age. [The conditions in a comb-honey-producing yard and a queen or bee producing yard are not the same. In the latter, breeding is forced in season and out of season by feeding. In the ordinary production of comb honey, breeding begins early in the spring and continues from the time honey begins to come in heavily. The gathered nectar often fills up the cells that would otherwise be occupied by the queen. The result is, her bodily vitality is not drained in the same way that it would be if she were given unlimited room, and forced by feeding. In the former case the bees might do their superseding soon enough. In the latter case would it not be more profitable to use young queens, especially those bred after or about the time of the main honey-flow?—Ed.]

BILATERAL multiple is the name of the latest honey-extractor, the invention of M. Etienne Jacquet. You put into the machine a single comb, or any number up to 20, pull down the cover, turn the crank for a time,

and there you are—both sides emptied without any reversing, automatic or otherwise, with no crushing of cells against wire cloth, and no danger of breaking combs out of frames. Twenty frames at a time, mind you.—*L'Apiculteur*, 60. [It is a little difficult to determine the precise principle of the extractor referred to above. If it is of the non-reversing type, the pockets arranged like the spokes of a wheel, the bottom-bars of the frames next to the shaft of the reel, or if all the frames are in the same plane, with the end-bars pointing toward the hub of the wheel, either or both have been thoroughly tested and found wanting. They have been illustrated and described in the journals. Thin honey, such as some beekeepers too often extract, can be removed from the combs on either of these two plans. But even then the combs are not cleaned. It is impossible to extract thick honey and get more than fifty per cent of it out of the combs. The only way to extract clean is to have the combs reversed so that the full strength of the centrifugal force can be applied. We went over these principles very thoroughly some fifteen or eighteen years ago, and found that a non-reversible machine, or, rather, a machine that extracts the combs without reversing, is a long way from a success.—Ed.]

ABOUT that quahking business, p. 747. The trouble with you, Mr. Editor, is that you are too up-to-date, discouraging all natural swarming, so that I am wondering whether you ever heard quahking. I have not for many years; but my recollection is this: In the evening go to a colony that contemplates sending out an after-swarm next day, and put your ear to the side of the hive. For a time you hear all sorts of gabbling, and then comes a clear tone above all others, long drawn out, followed by several others, each one shorter than its predecessor. That's *pip*ing. Immediately come one or more responses—each response a succession of short tones, the first tone as short as the last. That's *quah*king. The two may be made the same way; but do you think a cell or a barrel could account for the difference in length? [Yes, in the olden days we have heard quahking as well as piping. As we remember, there were two notes. The lighter one sounded like a tiny tin trumpet a long way off, while the other sounded like a larger trumpet closer by. While it is true one can hear both piping and quahking when a colony is about to cast a swarm, is it not probable that the piping is made by a hatched queen, and the quahking by another one in a cell as a challenge? And is it not probable that the

two sounds are made by the same organs in precisely the same way, but under different conditions? Naturally enough, the same sound inside of a wax cell would be weaker and more muffled than outside of it. Perhaps a barrel is not a fair comparison, but it would seem that the quahking would be shorter and more intermittent inside of a cell because there would be less air immediately available. We have to confess we do not know very much about this whole proposition.—Ed.]

UNITING is most easily done by the newspaper plan. Put a sheet of newspaper over one hive, and set the other over, with no chance for the upper bees to get out till they gnaw through the paper. In the same way a queen may be introduced by setting over the hive the nucleus containing the queen, with newspaper between the two stories. Sometimes you want to unite a queenless colony, A, with a nucleus, B, leaving all on the stand of the nucleus. Here's a good way: Take a single comb with adhering bees from A and give to B, making sure that the added bees are not more than half as many as B already has. Next day add another comb or two, and so on each day until all are used up. At the last leave a comb for any returning bees, giving these to B. [If this form of uniting be practiced in September it may occur during a spell of very hot weather; and then would there not be danger that the bees in the upper hive might smother for want of proper ventilation? Of course, if it were only a nucleus it might survive a boiling hot sun on a hot sultry day. When bees have access to an entrance they can control the temperature of the hive by ventilation; but when all means of access are closed, the temperature of the hive may go clear up to a point where it would kill bees and brood.

In our locality a thermometer placed on a hot day on top of a hive-cover painted white will reach from 120 to 130 in the sun. That would mean that the temperature of a closed hive might be 110. Such a temperature would kill some brood.

Practically speaking, however, the outside temperature at the time of uniting is generally low enough so the newspaper plan will work 99 times out of 100. But even then are there not some returning bees after a hole has been made through the paper?

The other plan of uniting comb by comb would be a slow process. We much prefer uniting the bees at two different yards where the bees are operated on the out-apiary plan.—Ed.]

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

At the present writing we are feeding all our increase, and looking hopefully for a sufficient fall flow to winter on. And we are not the only ones feeding. "Giving 'em a hundred pounds of sugar a day," a beeman from a neighboring county cheerfully announced last week.

* * *

Though I did not know Mrs. H. G. Acklin, may I not bring my woman's tribute of sympathetic appreciation to lay alongside the others heaped upon her memory? It always gives me a thrill of pleasure to hear of successful women—a pleasure intensified in this case by the realization that Mrs. Acklin met sorrow bravely, faced the world single-handed, raised a charming daughter, and was a lover of bees. And may I also send all my good wishes, like white doves, to the recent bride, Mrs. Howard R. Calvert? I suspect she knows that God didn't put all his poetry into rainbows!

* * *

We tried hard to have a field meet last month; and, for that matter, we had it, after a fashion, but not a fashion of our own choosing. The weatherman chose the mode; and, though the editor wisely suggests that the weather is of less importance than what was said, still in this particular instance (even the editor will grant this) the weather was of prime importance, because of what it caused *not* to be said. Briefly, it rained—not just that one day, but all day every day for many days. We were so sure it would stop by the date set that the meeting was not postponed. It can't rain forever, we said. But it almost can, we found out, for it almost did. So on the day itself, after standing first on one foot of our indecision and then on the other, we finally decided to go, because, since it evidently *was* to rain forever, we would have to hold our meeting in the rain some time, and it might as well be now. When the last nose was counted, we found we had gathered together seven brave and faithful souls. In the light of the adjectives, it might seem more modest to say six; but as it cost a dollar and a half to take the water-spots out of a delightfully absurd pongee coat, I shall allow myself to remain solidly classified with the virtuously faithful.

It was a good meeting for all that. No formality (with seven!), but an increased friendliness, which of itself makes a perfectly good reason for holding a meeting, though nothing else be accomplished. We talked informally of such things as different ways of making increase, the advantages and disadvantages of various-sized hives, stores for winter, and this year's crop—an average in this locality of thirty to forty pounds, and the prediction that next year'll be better, which it surely will if a clover year follows a wet year.

Foul brood came in for its share of shuddering comment. Our state inspector told how somebody had imported (unknowningly, needless to say) some diseased combs into the state, and things had immediately happened in his own apiary. "He has had his own punishment," Mr. Davis remarked, after hearing the story; "but what about the woods around him?"

"That's it," Dr. Ward answered with a sigh; "what about the woods?"

And that is it, apparently. What about the woods?

It was in the dash down the road for a home-bound car that a particularly lively shower spotted(?) the pongee coat. The shower passed before the car came, the sun slipped out, and there at the last was a rainbow, the brightest and most beautiful I ever saw, with a secondary one beyond, delicate as a rainbow dream. If I had thought of it sooner I'd have tried to put it into a poem. Yet, after all, no one could really put a rainbow into a poem. And why should we try? The poem is there in the rainbow. How all its colors rhyme! A perfect poem it is, and God wrote it, with the swing of eternity in its long rhythmic lines and a divineness of beauty in every lovely deepening shade, from the rim of red on the one edge to the rim of violet on the other.

Some other day we'll have a field meeting, boiling over with beekeepers and enthusiasm, and in the meantime perhaps it would be well for us to act on one of the suggestions of that wet windy meeting on the bungalow porch, and make the weatherman an honorary member of the association; then in the future he may show more tender consideration for the brand of weather he provides for the beekeepers of Tennessee.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

A headline reads, "Wintering bees on peppermint candy." I believe I could winter on that myself.

Keeping comb honey too warm will give it the appearance of being "water-capped," due to the fact that when the honey becomes too warm it runs against the cappings.

Mr. Scholl, will you kindly explain the difference between bulk comb honey and chunk honey? I am a little hazy on that distinction, and I presume there are others the same way.

I have just received word that a new beekeeper has arrived in the home of Mr. and Mrs. Wesley Foster. I have extended my most hearty congratulations, wishing all the blessings attending such an occurrence.

I read, page 686, Aug. 15, "The bee on the left was killed by a sting in the second joint of the front leg." It must have been a black bee. Colored folks are said to be very susceptible to injuries on their shins.

I saw an apiary last week that would burn "body and breeches" if fire ever got started in it. Weeds and grass were knee high, and as dry as tinder all around the hives and honey-house. If it should burn, the owner would have only himself to blame.

From the point of knowledge of the bee, San Bernardino County lost one of its foremost beekeepers on the 26th of this month in the death of Mr. Leroy Straight. He had been in poor health for many years, and had been failing rapidly for nearly a year. He died at the age of 63 years. His ability in successfully handling bees was excelled by few beekeepers of the state.

The California State Commission of Horticulture has issued a book of 500 pages, entitled "Injurious and Beneficial Insects." I am indebted to Prof. A. J. Cook, who heads the department, for a copy of the same. There are some data on enemies of the sage and other honey-bearing plants; but our old enemy the sage-worm, so called, seems to have been missed in the shuffle. This enemy is a worm of not more than $\frac{1}{4}$ inch in length, possibly more.

The egg that produces it is laid at the base of the button, in what has the appearance of being a sting in the button. It is at least a puncture of some kind for the depositing of the egg. The egg hatches, and the worm cuts its way around in the base of the button, destroying much of the bloom before it has time to open.

One of the most sudden and freakish storms burst upon us on the 26th of August. The morning was clear and bright. By noon the sky was fast becoming clouded. At one o'clock a dust storm broke all over the southern part of the state, and, to use a common expression, it was "some dusty." The dust was followed closely by rain in many sections, some places merely a sprinkle, at others a heavy downpour. The heat since has been very oppressive, the usual cool nights having disappeared for the time being.

Last week I was passing under a pepper-tree which was in bloom, and noticed many dead bees upon the walk and ground. I counted 19 on a space 4 feet wide and 12 feet long. At the same rate there must have been at least 200 dead bees under this one tree. I found upon further investigation that other trees had a like number under them. But the cause I cannot locate. Their bodies were distended much as in poisoning. Yet I have never known of bees having been poisoned by pepper bloom before. It is a mystery to me.

Mr. Doolittle, page 573, July 15, says "Cheaply reared queens are detrimental," and also, "As long as consumers insist on paying a low price for their stock, and queen-breeders advertise queens at \$50 a hundred, so long must they be content with the results of queens reared without proper care." Herein lies food for thought. Grinding out quantities of queens without proper individual care and examination is not conducive to the best interests of the consuming public. I have had sufficient experience with queen-rearing to cause me to believe that producing great quantities of queens is the only way that cheap queens can be turned out with profit, but the results are very much as Mr. Doolittle has said.

There is some honey being exported from the coast—the first for nearly a year. The

crop in general throughout the West is light. The demand for honey from some sections of the West and South is very good, being mostly orders from beekeepers who have failed to produce enough for their trade. Lots ranging from a few cases to car lots are being filled. Orders from as far east as Tennessee and as far north as Washington are being received. Much of the western crop will likely be absorbed in export and western orders, leaving the East largely to their own market. With these conditions a steady market should be maintained, and a stronger feeling exist. Why should prices rule lower when the great West seems able to dispose of its holdings without invading the East materially?

An editorial, page 699, Sept. 1, reads in part: "If a queen is a year or two old she will let up on her egg-laying soon after the harvest." There is nothing I know of that would be of more worth to the beekeepers of this section than to impress this one fact on their minds. Our long dry summers make it imperative that we have a queen at the head of the colony that will force breeding matters in the face of adverse conditions, and give us as liberal a supply of young bees for wintering as possible. This can be done only with young queens, and to reach the limit of success every colony should be requeened immediately after the close of the honey-flow. Plenty of young bees and an abundance of stores are the best safeguards against spring dwindling. I am glad the editor said "a year or two" old. My way of putting it would be to say a year old, for that would cover it quite fully.

A certain orange-distributing company is sending out a series of educational folders relative to educating the public as to how best to prepare and serve oranges daintily. On one of these is the startling statement that people eat with their eyes. Literally speaking, it is a startling statement, but figuratively it is correct. The more dainty, clean, and tasty an article looks, the quicker it sells. This is especially true in the honey business. Last summer, while in the East, I visited a grocery owned by an old schoolmate. On the counter was a case of honey that was certainly the most unappetizing of any I had ever seen, being not only black but ill shaped and dauby. I asked my friend if he sold any great amount of it. He said no; there did not seem to be much demand for honey. I did not express my thoughts, but nevertheless it occurred to me that, had he had

some in stock which looked a little more attractive, he would have been able to increase his sales, for a buyer used to good honey would not carry home the stuff he was trying to sell. I doubt if you could fool a blind man the second time on such an article. Fancy goods bring fancy prices. The world is strong on looks, regardless of what it may be.

On page 701, Sept. 1, I seem to be much in the position of the lost parrot. Dr. Miller and the editor both take a whack at me in the same paragraph, so I must exclaim as did the parrot, which had been the property of the matron of a large depot. His cage had long been hung near the exit gate, and eager travelers had been told so many times by the guards, "One at a time, gentlemen, one at a time," that the parrot thoroughly learned the sentence. One day he got out of his cage and into a park near by, where the bluejays were making life miserable for him when he was found. But for all, he was loudly shouting, as an occasional feather was plucked from him, "One at a time, gentlemen, one at a time."

There seems to be a disposition shown to "knock" yellow bees, and I am placed in the position of lawyer for the defense. To that end I will state that individual cases should not condemn the entire race. The fact that breeding for color has to some extent decreased the efficiency of the goldens, while two or three well-known strains of three-banders have been widely distributed for their gathering qualities, is no sign that the golden strain could not have reached just as high an efficiency had they been bred for the same quality and not for color alone. I have introduced three-banded queens from some of the best-known breeders in the country that were actually not worth the time it took to introduce them. The same has been true with the goldens; but the difference between the two has not been so great as one would be led to believe. Wishing to secure the very best golden strain in the country I recently wrote several breeders as to the base of their stock, whether it contained Cyprian blood or was originally Italian. One breeder wrote me that the base of his stock was from three of the best-known breeders of queens in the country, and gave me their names. His first aim he said was working quality; second, gentleness; then color. With a golden strain bred for these characteristics I see no reason why there cannot be a strain of goldens equal to or perhaps superior to any three bands obtainable.

NOTES FROM CANADA

J. L. Byer, Markham, Ontario

As mentioned in my September Notes, clover is very rank, and gives promise of being abundant for next year; so, after all, the wet weather has perhaps been a benefit in one way at least. Reports were circulated last spring that, owing to the war, alsike would not have a market at all; but as any seed harvested this year is bringing around \$8.00 a bushel as it comes from the machine, likely many acres will now be left for seed which otherwise would have been plowed under this fall.

On page 701, Sept. 1, Dr. Miller speaks of his bees differing from mine in that they have been very strong all through the wet season—a slight misunderstanding, I suspect, as I referred to the fact that, with so many old bees carried over the winter, during the early cold wet weather they died off rapidly. For the past two months we have had rain by the tons day after day, with hardly a let-up, and at present our colonies are abnormally strong—in fact, one would wonder where all the bees are going to go when supers are all taken off.

September 10.—Beautiful summer-like weather, and yet there are hundreds of acres of grain still not cut, and, judging by present conditions, very much of this grain will be a total loss. All records in regard to precipitation have been broken for these parts; and even if we have ten days or more fair weather, the ground is so saturated that in many places it will be impossible for horses or machinery to get on the land to garner the spoiling crops. The fine weather came too late for buckwheat in so far as a crop of honey is concerned. It yielded well during the few fair days we had; and in our own case, at least, we shall have more than enough of this honey to pay for any feeding required. That is something to be thankful for anyway, when the high price of sugar is concerned.

With September here again, once more the question of aster stores looms up. While there is nothing doing here in York Co. among the bees, the apiary up north is again storing aster honey in the supers, and also plugging the brood-nests solid. It is coming in earlier than last year, and

the yield seems to be more abundant also. In addition to the asters, the goldenrod is also yielding, while last year the latter plant yielded little if any honey. I hardly know whether to be glad or sorry for this late fall flow again, and I think it will take me till next spring to decide the question. One thing seems sure at present; and that is, that the bees up there will go into winter quarters again solid on these questionable stores; for although I intend to send up sugar and feed wherever it can be done, judging by last fall's experience the bees will take little sugar syrup if weather is fine for a few days yet.

Regarding the matter of queens quacking or piping, perhaps I have been at fault in not distinguishing the difference (page 631, Aug. 1); but I am not a musician, and so am unable to count the length of the notes properly. I have generally applied the first term to queens in cell yet, and the latter to those loose in the hive. But once more I must express surprise that so good authorities as we have mentioned have not heard the queens calling except on comb, while it is such a common occurrence here. Just a few days ago I placed a queen in each coat pocket, one on each side, intending to go to an outyard. I was helping Mrs. Byer move some furniture, when all at once both queens started in "conversation." For the moment I had to look where the noise was coming from, when I happened to think of the queens in my pocket. Mrs. Byer remarked, "They have been squawking all the forenoon while lying on the sideboard." Perhaps the term "squawking" will cover all included in the two usual terms; anyway, we often hear queens thus passing the time when we get them through the mails.

Reports of market conditions in last issue's editorials have been read with interest. Here on this side of the line, where war conditions would necessarily seem to affect us worse than residents of Uncle Sam's domains, we beekeepers have had a genuine surprise—at least one of them has had, anyway. While we expected slow sales at somewhat lower prices than usual, owing to a combination of circumstances, we are finding the demand extremely keen for good honey. Vegetables and fruit have been quite cheap; but honey is selling like the proverbial "hot cakes." We cannot thank

Continued on next page.

BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado.

Our honey-flow in eastern Colorado did not last into September as was hoped. In a very few restricted districts a two-case crop of comb honey was secured; but the average for eastern Colorado will not be one case. Western

Colorado conditions are somewhat better, but a normal crop has not been secured. Grand Valley from Glenwood Springs to Fruita reports a very good late flow lasting into September. Some will secure a yield of two cases of comb honey. A few cars of comb honey have been shipped, and within one month very little comb honey will be left in the state. The indications are that the local trade will be without comb honey on account of better prices being secured in the East. A number of cars have been sold at more than \$3.00 a case for the two first grades, and local shipments have brought from \$3.25 to \$3.50 a case. The comb-honey producer who can hold his honey for the local trade will be assured of good prices later in the season.

The Arkansas Valley, from Canon City to the state line, has had the poorest crop on record for the whole district. Ten to fifteen pounds of extracted honey is certainly a very unsatisfactory return, and some producers will not get that much.

THE WEATHER.

Such a season as we have had this year is very unusual. A deficiency of about 300 degrees for the summer months, and a precipitation of three inches above normal, did not help the beemen. The short snowfall of last winter was compensated by the heavy summer precipitation. In fact, the weather was so cool that the snow on the ranges, though very scarce, did not melt very appreciably. Sweet clover of the new growth has come up well, and we should have an abundance next year. We have not had a favorable growing season for farm crops, and the nights were so cool that it was with difficulty that the bees built combs. The outsides of the supers were rarely finished, and much foundation was chewed up.

About a week was all the summer we had, and very few real honey days came. The foothills seemed to hold great stores of cool weather. There was not any district in northern Colorado within fifteen miles of the foothills that made more than a case of comb honey to the colony. But further out from the mountains the days were very much warmer, and bees did somewhat better.

THE MARKET.

The demand for comb honey has been very brisk so far; and as soon as the buyers find out how short the crop is, the price will go up more. Boulder County will not produce more than three or four cases of comb honey. In past good seasons as many as thirteen cars have been shipped out. The local market this year will use (if it can get it) between one and two cars of comb honey. Idaho honey has brought from \$2.50 to \$3.00 a case according to the grade, and close to \$3.00 has been paid for honey in western Colorado where the freight rate is about twenty cents a case more to the East than the Colorado common-point rate.

Those flower pictures shown in my article on p. 619, Aug. 1, were all taken outdoors. The camera was taken to the flowers, and not the flowers to the camera. In this way a more natural effect is produced, although clearness of detail is lost, and a satisfactory background is not always possible. The pleasure of flower photography is increased when one tries to catch bees in the act of gathering pollen or sipping nectar. Several days each year can pleasantly and profitably be spent by the beekeeper in investigating the sources of pollen and nectar, and photographing the bees at work.

Continued from preceding page.

our wholesale friends for this state of affairs, as they have done nothing to help us, and have in some cases, at least, tried hard to bear the market. Some sold quite early at a figure considerably lower than advised by the committee; but I expect by this time they will know that the sacrifice was entirely unnecessary. At any rate, the local demand in our own community was never so good, and not a word is said against prices asked. The west market is hardly started yet, as the people are too busy harvesting their great crop to think of buying honey; but there is no doubt that they will be heard from later on, and I now believe that every pound of good honey produced in Ontario this year will find a market at a good fair price, all things considered.

As to the dark-honey market, I know nothing of what we may expect; but anyway the crop of buckwheat is very light, so there should be no trouble in getting rid of it at a fair figure.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

HIVE-MAKING.

"I am thinking of making my own hives the coming fall and winter. I am quite used to carpenter work, and think I can save quite a little in making my own hives. Can you give me a few pointers in the matter of hive-making?"

The first thing that a beginner, or those of small experience in keeping bees, should learn is that hives cannot be thrown together in a haphazard way, even where the material is purchased from a manufacturer of beekeeping supplies. Few things, including stings, are more provoking or try the temper more than a set of hives which vary in size, or which have parts that are ill-fitting or poorly made. The first thing our questioner should do is to make a careful study of hives to find out just what he wants. If he proposes to produce extracted honey his hives may be somewhat different from a design suitable for producing section honey, as the accuracy required for producing fancy comb honey is not necessary when producing the extracted article. But with hives for extracted honey, every piece should be cut accurately from well-seasoned lumber without the variation of even a sixteenth of an inch. And for real fancy comb honey, even a difference of that much would not answer in a season with a profuse flow of nectar.

Then a form is needed for putting up the hives, frames, sections, etc., so that every part will come out square and fit accurately with no loose joints or leaky roofs. All should be made perfectly square—not even a trifle diamond-shaped. Frames even just a little out of true should not be tolerated, as the bees may stick one end to the end of the hive or to another frame, and at the other end build a bit of comb between, thus making things anything but agreeable when the frames need to be handled.

Be sure that the space between the top of the frames and the honey-board or cover is just right and will stay so. If the top-bars are too light they may sag when the combs are filled full of honey, as is often the case in a good season, thus making the space in the center $\frac{1}{2}$ to $\frac{5}{8}$ inch, while it is only $\frac{1}{4}$ at the ends. Under these circumstances this greater space will be filled in with comb and honey, disgusting even the "slipshod" fellow.

See that just the right space is given at the ends of the frames; for if too much is given, combs will be built between the ends

of the frames and the hive; and if too little, the bees will fill it up with propolis. The same applies to the space underneath.

For these reasons only well-seasoned lumber should be used, and that of a kind that is not subject to much shrinking and swelling. Pine is probably the best of any, though a good quality of hemlock will withstand shrinking nearly if not quite as well. It is harder to work, however, and is more liable to check and split during very dry weather. I once visited an apiary in which the hives were made of basswood, the apiarist thinking that, if such hives were kept well painted, they would be as good as any made of the higher-priced lumbers. But when I came to look over these bees the brood-chambers had shrunk so as to let many of the frames rest on the bottom-board, and the bottom-bars were glued fast so that it was almost impossible to manipulate the frames at all.

Not only should the frames and brood-chambers *be* and *stay* of the right size, but they should be so arranged as to be spaced exactly the right distance apart. I remember looking over one apiary where the frames were all the way from 1 3-16 inches to two inches apart from center to center, this making the combs so that they could not be interchanged after the bees had filled them with honey during a flow of nectar. After using different bee-spaces I still insist on having the combs $1\frac{1}{2}$ inches apart from center to center. Many advocate from 1 5-16 to $1\frac{3}{8}$; but from a series of years, covering all kinds of weather, my best results have come from the $1\frac{1}{2}$ spacing.

The accuracy needful in making hives is much more exacting for the supers where sections are used in securing comb honey in marketable shape. A variation of a sixteenth of an inch cannot be tolerated with sections. Suppose our super holds ten rows of sections, as many of the supers now in use do, and we find when the sections are put together they are a thirty-second of an inch over; then we shall be in trouble because they will not go into the super. Again, if not quite large enough, or each of them the same part of an inch too small, we have a space to be filled with propolis, very much at the expense of the appearance of the sections when ready for market. The accuracy necessary for *supers* for *sections* is so important as to be beyond any profit in the making by any carpenter, no matter how skillful he is in the use of tools.

GENERAL CORRESPONDENCE

A SONG OF HONEY

BY GRACE ALLEN

We find among the merry songs of eatables that please,
 Full many a lay of curds and whey, of apple pie and cheese—
 Of luscious figs and purple grapes, and apples round and red,
 Of pies with plums for grasping thumbs: but after all is said,
 Is anything better than honey, fragrant, sweet, and sunny,
 Gathered when days are warm and bright by a hundred thousand bees?
 Is there anything all your money can buy that is better than honey,
 With the scent of the glowing hearts of flowers and a hint of a woodsey breeze?

Now some may sing of snow-white bread, but brown's the bread for me
 Coarse graham flour, and baked an hour, the crust so rich to see;
 A taste like nuts in autumn when the leaves are gold and red;
 Then bring sweet milk, and honey sweet, for, after all is said,
 Is anything better than honey, fragrant, sweet, and sunny,
 Borne by a thousand silken wings through a million laughing beams?
 Is there anything all your money can buy that is better than honey,
 With every drop like the taste of food we dreamed in a childhood dream?

Let other rhymsters all the joys of jolly dumplings sing;
 No ballad I, of salad, pie, or pudding-sauce shall bring:
 But through my days I'll sing the praise of crumbly graham bread
 With creamy milk and clover honey; for, after all is said,
 Is anything better than honey, fragrant, sweet, and sunny,
 Made by a magic spell and the charm of June's bewitchingest ways?
 Is there anything all your money can buy that is better than honey,
 The autumn's precious heritage of summer's fairest days?

THE MINERAL CONSTITUENTS OF HONEY

BY J. A. HEBERLE, B. S.

(Condensed from an article by Dr. Fehلمان in the Schweizerische Bienenzeitung)

To-day, as in old times, honey as a popular remedy is esteemed by old and young. Less valued and too little known is honey as an article of food. As such, for easy assimilation and savor, it stands at the head. We may assume that it was also one of the early foods of mankind, since in the Old Testament the promised land is spoken of as flowing with milk and honey, implying that the best of food was there in abundance.

Pliny, 2000 years ago, called honey the sweetest and most wholesome of juices. "There is no pleasanter or better remedy to save mortals from deadly evils." The ignorance of the general public in regard to honey as food is astonishing. Just as water goes direct into the blood, so does honey, leaving no residue. It is assimilated at once, and changed to energy. For food it is far superior to sugar, which is to-day highly esteemed as food among the sweets.

Cane sugar in the stomach, through the gastric juice, must be first inverted—changed to that form of sugar of which honey is principally composed. Honey contains only a small amount of cane sugar. The fact that honey is in the form in which it can be at once assimilated without taxing the digestive power is of great importance. The need of sugar by our body is, as a rule, much greater than is commonly supposed.

The starch we take in our food must first be changed by our digestive apparatus into dextrine and then into sugar—not cane sugar, but dextrose, the principal constituent of honey. From this one fact we might call the sugar in honey physiological sugar. This saving in the digestive power, when we eat honey, is due to the fact that the bees, when they gather nectar, which for the most part is cane sugar, change it to fruit sugar. On account of the importance of invert sugar to our bodies we must con-

clude that honey ought to be consumed in much greater quantity than has been done heretofore.

Besides the sugar in the form in which it is assimilated without any work from our digestive apparatus (and this constitutes the bulk of honey) there is also some albumen in it, in soluble form, readily assimilated. The amount of albumen varies greatly, according to Dr. Fehlmann, whose analysis showed honey from buckwheat and heather is rich in albumen.

Dr. Langer Graz has shown that the albumen in honey reacted as of animal origin. Further investigations will show whether there is any albumen present in nectar; and, if present, whether it is for the same blossoms a somewhat constant quantity; also whether the albumen in honey has only undergone a change, a transformation, or whether the bees add it to the honey during the process of inversion.

MINERAL MATTER IN HONEY.

Besides sugar and albumen in a form to be assimilated, honey contains inorganic elements. The amounts are small, but, notwithstanding this, are very important. Some might think it doubtful that mineral matter could be present in honey, since it is perfectly soluble in water. If honey is burned (oxydized), a residue of a dirty-green color remains that cannot be further destroyed. It represents the inorganic elements contained in the honey. The greenish color is due to the manganese.

IMPORTANCE OF MINERAL MATTER IN OUR FOOD.

The following experiment may be accepted as proof of the necessity of mineral matter for our bodies. If an animal is fed on albumen, fat, and carbohydrates, from which all inorganic elements have been removed, the animal will soon become uneasy, lose appetite, and finally it will get cramps, grow weaker and weaker, and, if the experiment is continued, will die. This above plainly enough that inorganic elements are for the animal body a necessity. Other experiments seem to show that the body endures complete abstinence of food better than the lack of inorganic constituents in the food. The inorganic elements are an important constituent part in the organs and fluids of the body, and for its well being must be present in sufficient quantity. A superabundance seems to do no harm.

INORGANIC ELEMENTS PRESENT IN HONEY.

The animal body requires for its well being the following inorganic elements: Phosphorus, P.; iron, Fe.; calcium, Ca.; magnesium, Mg.; chlorine, Ch.; sodium, Na.;

potassium, K.; sulphur, S.; manganese, Mn.; and silicon, Si. As to the importance of manganese and silicon, opinions differ; but both of these elements are present in the ash of the honey. Until recently the inorganic parts in honey had received but little attention. Some are of the opinion that the ground on which the plant grows would influence the amount of inorganic elements in the nectar; for instance, that land with much iron would produce nectar or honey with much iron content. Others hold that certain plants have a special affinity for some of the inorganic elements, and will take these up while they partly or entirely neglect others. We know that the ash of the tobacco-plant contains lithium, Li.; and the ash of the grapevine boron, B.

The above enumerated inorganic elements that the animal body requires *are all found in the ashes of honey of various origin.* The only exception is silicon. Dr. Fehlmann explains that he could with the microscope prove the presence of silicon particles in some of the honey, so it may be that silicon may be present as a mechanical impurity, not an integral part.

THE INORGANIC ELEMENTS PRESENT IN ALL HONEY.

Qualitatively the honey from various parts and various plants showed no difference regarding the mineral constituents; but quantitatively they showed considerable variation. Honey from the Alps showed five times as much ash as honey from buckwheat, while honey from the Black Forest from the fir called *Waldhonig*, a honey-dew honey of vegetable origin, showed even ten times as much ash as buckwheat honey.

It is not known how much of the inorganic elements the human body needs; but a part at least may be supplied by eating honey, which contains these elements in a *readily assimilable* form, and this is very important since only the assimilable forms of the inorganic substances may benefit the body.

IRON.

It is generally known that iron is very important to the human body. It is an important constituent of the red blood corpuscles. Chlorosis is a sign that the body is suffering from a lack of iron. For such persons honey is a very valuable medicine. Why not in such cases eat honey regularly, which supplies the iron in the most assimilable form, instead of artificial iron preparations? Besides iron, manganese seems also to influence favorably the building of blood.

PHOSPHORUS.

Phosphoric acid with calcium is the prin-

cipal constituent of the skeleton, but is also found in the brain and nerves. It is often prescribed in chlorosis and for convalescent persons, especially in preparations which are closely related to the form in which it is present in the brain, as ovalecthin, phytin, glycerin phosphates, etc.

CALCIUM.

Calcium is an important part of the skeleton and teeth, but is also found in the soft tissues of the body, and is probably a necessary part in the protoplasm of most cells. It is continually exchanged, and therefore an indispensable part of our food. Calcium and potassium seem also to influence the work of the heart.

This surely ought to suffice to show the eminent value of honey as food. Sugar, although a valuable food, has no trace of inorganic matter. It consists of carbon, hydrogen, and oxygen only. Considering the excellent qualities of honey, and its moderate price, it should be used far more extensively. It should be on the table instead of syrup, molasses, etc. It should be eaten daily by everybody in small quantities, especially by those with an impaired digestion, convalescent persons, those suffering from anæmia and chlorosis. Honey is also beneficial to children and aged persons.

HONEY IN REFRIGERATORS

BY R. F. HOLTERMANN

On page 659, Aug. 15, Mr. Louis H. Scholl, and then on page 698, Sept. 1, the editor and Dr. Miller, have something to say about putting honey in the ice-box. I should like to add a little to the discussion.

For years I have said that if one wants to get the best flavor out of honey he should eat it cold. Whenever we have been anxious to create a good impression of our honey I have made a point to have it eaten cold.

One who is in doubt can try this experiment. Warm the honey, and eat it that way; then try it just taken out of the ice-box. In my estimation one has a very peculiar taste who prefers the hot honey. I rarely come across the consumer, in selling honey, but I advise eating it cold.

GRANULATION.

It is the variation in temperature as well as other things that causes granulation. Variation in temperature causes expansion and contraction of the honey; and the movement of the particles tends to granulation (this with me is theory based on speculation from observations and reasoning). Honey keeps liquid longer when the temperature is fairly high; but honey on ice, or kept in the cold, say a freezing temperature, does not granulate rapidly; and varying temperatures with downward dips is probably the most favorable condition for granulation. My advice is, eat honey just out of the ice-box.

Brantford, Canada.

WHY USE HONEY IN COOKING

BY B. KEEP

The great benefits to be gained by the more general use of honey in cooking, more particularly in baking, are not as well known as they should be. Not many cooks possess originality; but once a trial is made in using honey, it would seem that the very great advantages of it in any sort of cake, cookies, crullers, and some kinds of brown bread, should induce further trials.

Where cake is intended to be dry and crisp, no honey should be used, as it confers a tendency to become and to keep moist, and it may be depended on for this effect. Same baked stuff is naturally rather dry and crumbly, and is not "real good" if it is otherwise; but by adding honey this crumbliness is much abated without injuring

other characteristic qualities. This applies to corn bread and corn or hominy muffins, molasses cake, etc.

Certain cakes are notably good only when "fresh;" and usually whatever is not consumed at once is wasted. The freshness of such cake can be retained for a day or two longer by adding honey to the ingredients while mixing.

Light honey does not impart any appreciable flavor, so that it can be added in proper measure to almost any recipe where a moist keeping quality is desired, without making any other change, excepting, perchance, to use a little more flour. An excessive addition would be useless and wasteful, and might impart some flavor.

The ordinary recipes produce about an average-sized cake or batch; so it may be safely said, use a cooking spoonful of honey for the ordinary recipe, and more or less in special cases.

There are recipes for honey cakes where the honey is intended to give a flavor. In such cases the honey must have a rather strong flavor, and is used in much larger quantity.

On account of chronic conditions many persons cannot indulge in ordinary sweets. In such cases honey may often be substituted, whereby many things may be eaten without the usual unpleasant effects, and

many new combinations may be discovered and enjoyed. Honey on nice ripe strawberries makes a fine combination. Sliced banana with honey is very tasty, and makes a satisfying dessert after a spare meal. Thoroughly ripe currants with honey, crushed in the individual dish by means of a fork, goes very nicely with roast meat. Boiled rice (plain), with a little butter added after the cooking is finished, and honey on the top when served, makes a very acceptable and easily digested evening meal or dessert. In fact, there is no end to the use for honey if one will look about a bit.

Lyndhurst, N. J.

THE BLENDING VALUE OF HONEY IN COOKING

BY RACHEL F. DAHLGREN

Honey and milk (or, still better, honey and cream) cooked or uncooked is an ideal combination. Honey may, therefore, be used to advantage for sweetening ice-creams, gelatine creams, and such delicate blanc-manges as are made with rennet and Irish moss.

Honey combines particularly well with apples, oranges, bananas, peaches, and dried fruits. Cakes made with honey should be allowed to "ripen" for a day or two at least. Honey fruit cakes, hermits, and the like, are better at the end of a fortnight.

Steamed fruit puddings gain greatly in flavor when made with honey instead of molasses. The use of graham or whole-wheat flour in such puddings is recommended.

Bitter almonds, orange, lemon, and fruit

flavors generally, blend well with honey, as do also anise, coriander, and other spicy seeds used in cooking.

The small sour wild plums common in many parts of the country make a delicious sweetmeat when preserved in honey. Cook with a very little water until they burst, then remove the stones, add 2 scant cups of honey to 3 cups of fruit, and simmer gently for 20 minutes.

In sweetening delicate custards, cake fillings, etc., with honey, it is best to add the latter immediately before removing them from the fire. Finally, fresh comb honey is the most exquisite food product known to nature; and with fresh brown biscuit, butter, and new milk, it furnishes a meal fit for the gods.

Redding, Ct.

HOW I USE HONEY

BY DR. C. C. MILLER

In lieu of breakfast each morning I have a bowl of weak postum, with cream and honey, and a little oatmeal. I rarely eat the oatmeal—just drink off the liquid. It takes about $1\frac{1}{2}$ ounces of honey, and that amount I've taken every morning for years. I don't take it because I like honey in drink better than sugar. I don't take it because I'm a beekeeper and want to help the honey-market. I take it simply and solely because I want to live as long as I can, and be as well as I can while I do live. And I think it makes a difference worth considering whether I put upon my digestive system the burden of inverting so much cane sugar, or giving it honey which contains sugar ready for direct assimilation.

An ounce and a half a day seems a mere trifle; but let us figure a little upon it. Multiplying by 365 it gives us 547 ounces, or a little more than 34 pounds for a year's supply. Now suppose each of the hundred million of people in the country were to use the same amount. It would take three billion four hundred million (3,400,000,000) pounds. That's no trifle, is it? At 10 cents a pound it would come to \$340,000,000. Dr. Phillips says the average annual crop of honey in the United States amounts to at least \$20,000,000. That would have to be multiplied by 17 to make it \$340,000,000. Plainly, if every one should go on consuming $1\frac{1}{2}$ ounces of honey daily, beekeepers

Characteristic view of a Dutch dining room. Notice that honey in three different forms is shown on the table. Sent by Hans Matthes, Breukelen, Nederland.

would have to increase their output, if not 17 times, at least 10 times.

It would be worth something to increase the demand for honey; but it would be worth a great deal more in the way of the health of the nation if that $1\frac{1}{2}$ ounces of honey could replace a like amount of the something like 4 ounces of sugar consumed daily.

I'm not limited to an ounce and a half for my daily ration. I may use twice as much in the rest of the day, or I may use very little. But I know nothing very definite about the rest of the day, while I do know that $1\frac{1}{2}$ ounces has been my regular morning allowance for years.

I'm not posing as a heavy consumer of honey. I'm not a heavy consumer of any kind of food. At 84, with very little muscular activity, it doesn't take much fuel to stoke the furnace. If I should eat as much as the average, I shouldn't expect to live many days. If I were in young or middle life, with average muscular activity, I hardly think a quarter of a pound of honey daily would be enough. The point I am trying to make is that, if we could by some means get every one to use just a little honey daily, it would make a big difference in the honey-market, and a more important difference in the health of the people.

Marengo, Ill.

A GOOD PROOF OF THE FOOD VALUE OF HONEY

BY RALEIGH THOMSON

I want to give Mr. Chadwick something to dream about. He says that honey is a luxury, always has been, and always will be. Now I think he is badly mistaken. If honey is a luxury so are butter, eggs, cheese, and many other things that are called a necessity, while honey sells for less than either. Honey is about one price the year round. We sell our honey at 15 cts. for comb and extracted, and we get from 15 to 40 cents for our eggs, and from 20 cts. to 35 cts. for our butter fat, and cheese runs from 20 cts. to 30 cts. When a child

asks for something to eat I ask him if he wants bread and butter or bread and honey. Nine out of ten will say honey, and it will not hurt them, either. We have raised six children, and they have all eaten honey. We average one pound per day, and have used it this way for 20 years. The boy weighs 180 lbs., and the five girls will reach the 140 mark each, and we are of a family of small people at that.

Twelve and one-half cents for comb and 5 cts. for extracted honey is not enough.

Underwood, Ind.

The large baking companies use carloads of honey in the manufacture of their cakes and cookies. The frosted and unfrosted honey jumbles may be obtained at almost any grocery.

HONEY RECIPES USED IN COOKING

A Collection of New Recipes for Wholesome and Delicious Dishes as Prepared and Used by Our Readers

HONEY FRITTERS.

One cup sour milk with soda or sweet milk and baking-powder; 2 eggs; $\frac{1}{2}$ cup of honey, extracted; one scant tablespoonful of lard; one scant teaspoonful of salt; flour for stiff batter; fry in deep fat, dipping with teaspoon. Serve with extracted honey, slightly warm.

HONEY TARTS.

Make rich pie crust; cut out the center of two rounds; cut with biscuit-cutter; place one, without cutting, on the bottom; bake light brown; fill with the following: One cup honey, extracted; $\frac{1}{2}$ cup of butter; one whole egg; extract of lemon, or juice of one. Fill just before using, and sprinkle with nuts or whipped cream. This is fine for lunch.

HONEY SHORTCAKE.

One quart flour, 2 teaspoonfuls baking-powder; $\frac{1}{4}$ teaspoonful of soda; heaping tablespoonful of lard; a little butter. Mix soft with sour milk. Bake in a square cake-tin. Split, and fill with the following: One pint of cream, whipped with a little powdered sugar; one cup honey; white of egg; add a lit-

tle lemon juice; whip lightly and spread on the cake, spreading first the honey whip, then cream, heaping the cream on top; after first spreading the honey whip, nuts may also be used if liked, and you can omit the lemon, or use with fruit. Tart fruit is best.

FILLING FOR CAKE.

The following is good for cake-filling, and makes nice sandwiches, or may be used as sauce for pudding. It is also fine by leaving out lemon and egg for hot cakes, waffles, or toast softened with little milk or cream.

One heaping tablespoonful of butter; one teaspoonful of lemon juice; white of one egg; one cup honey extracted. Beat the egg very light; add butter; add honey; beat again; then lemon last. Beat hard as you add each ingredient.

HONEY-ROLLS.

Bread sponge for 18 rolls; mix a tablespoonful of lard or butter or half of each, and let it be a generous spoon. Add a little salt; mix as for rolls, and let it rise; then roll each one flat, putting a generous teaspoonful of the following filling in the center of each; fold sides and ends. Pinch well to keep the filling in; let it get light; brush with milk and honey, and bake.

One tablespoonful of butter; one cup of honey; $\frac{1}{2}$ cup chopped nut meats; whip the butter and honey; add nut meats last; sprinkle with nut meats if you wish it extra nice.

M'QUESTON BISCUITS.

Light sponge for fifteen biscuits; one cup of honey, extracted; half a cup of lard; a little salt; mix, and let it get very light. Roll out, and cut with doughnut-cutter. The doughnut-cutter is important in making these. Brush with a little milk and honey; let it get very light, and bake. This is nice for tea.

FAMOUS BISCUITS.

These biscuits are famous when eaten with

Did you ever try honey and cream on "grape nuts"?

An ideal breakfast: Honey on grapefruit; comb honey and cream on shredded wheat; honey cereal coffee.

honey. There are always calls for more.

One full quart flour; one tablespoonful of lard; one teaspoonful salt; $\frac{1}{4}$ teaspoonful of soda; one heaping teaspoonful of baking-powder; sour milk to mix, not very stiff, but work slightly. Soft flour, soda, baking-powder, and salt all together; work in the lard; make a hole in the center of the flour, and pour in the milk. Mix with a spoon until rather soft dough; work, roll, cut, bake in a quick oven.

Cambria, Wyo.

MRS. CHAS. BOWLES.

HONEY GINGERBREADS.

I produce only comb honey, but sometimes there are leaky sections, or in some other way I have a supply of liquid honey on hand. If my family know about it a demand is immediately made for honey gingerbread cookies or honey gingerbreads, as they call them. They keep indefinitely, and get better the older they are. It is made thus:

One cup each of butter, honey, sugar, and nut meats; one egg; 2 teaspoonfuls of soda; one tablespoonful of ginger. Mix stiff with flour—usually about four cups. Drop by the teaspoonful on a greased pan, and bake in a moderately hot oven.

Keokuk, Ia., Aug. 7.

MERTA MITCHELL.

DELICIOUS SQUASH OR PUMPKIN PIE.

One quart or its equivalent of canned pumpkins or squash; one quart new milk; 3 eggs; $1\frac{1}{2}$ cups honey; one cup of sugar; one level teaspoonful cinnamon; 1-3 teaspoonful ginger; 1-3 teaspoonful cloves; $\frac{1}{2}$ nutmeg; $1\frac{1}{2}$ rounding tablespoonfuls flour; one level teaspoonful salt; one large tablespoonful butter. This makes three large pies. The crust should be rich; and the pie is much improved by frosting or covering with sweetened whipped cream. Pie should be baked slowly and well.

Garden City, Mo. MRS. LUCY M. WAGNER.

YANKEE CRULLERS.

Three eggs, one cup of milk, 2 cooking spoonfuls of honey; one cup sugar (more or less to taste); $\frac{1}{2}$ teaspoonful of salt. Mix these all well together, then add 3 teaspoonfuls (heaping) of baking-powder. Sift the baking-powder and flour together into the mix—enough to make a rather soft dough. The mixing should be done with a spoon. The dough should stick to the hand or board, and therefore cannot be worked with the rolling-pin. Flour the

board and the hands, and flatten a portion of the dough with the hands. Cook in lard not too hot, but give a little more time.

OLD ORCHARD CORN BREAD.

Three eggs, one pint milk, 2 cooking spoonfuls of honey; 2 large tablespoonfuls of sugar; one large tablespoonful of butter; one level teaspoonful of salt; three teaspoonfuls of baking-powder; 2 parts corn meal to one part flour—enough to make a batter which will drop (but not run) off the spoon. The oven should be moderately hot, and be sure the loaf is baked through.

GRANDMA'S HOMINY MUFFINS.

Two cups cold boiled hominy; 2 eggs; one pint milk, scant; 2 cooking spoonfuls of honey; one level teaspoonful of salt.

Mix these all well together thoroughly. Then add 2 heaping teaspoonfuls of baking-powder mixed into corn meal and flour, equal parts, and of this mixture use enough (about two cupfuls) to make like a stiff cake dough. The southern finely ground white corn meal is preferable, as it has a fine flavor. Bake in a rather hot oven to a golden brown. It may be baked in a shallow loaf, but is much better baked in muffin-rings or patty-pans.

B. KEEP.

HONEY MUFFINS.

Half a cup of butter; 3 tablespoonfuls of honey; 2 eggs; $2\frac{1}{2}$ cups of graham flour; $\frac{1}{2}$ cup white flour; 3 teaspoonfuls baking-powder. Add milk to make a thick batter. Cream the butter and honey together, add the eggs well beaten. Mix the baking-powder with the flour, and add to the other ingredients, alternately, with the milk. Bake in a hot oven.

A FRUIT DESSERT.

Equal quantities of peaches, raspberries, and stoned cherries, arranged in layers. Pour over it half a cup of honey and the juice of half a lemon mixed together. Cover, and let it stand for a few hours.

DESSERT FOR DYSPEPTICS.

Rice, $\frac{1}{2}$ cup; white of one egg; 3 tablespoonfuls of honey; half a lemon. Wash the rice through several waters. Sprinkle it into one quart of boiling water, salted. Boil hard for half an hour. Whip the white of the egg stiff; add the honey to it gradually, beating constantly; then add the lemon juice. Strain the rice, and shake dry; and, while still piping hot, add it to the egg-whip, beating well. Turn into a glass dish and serve cold, with cream or without.

Erindale, Ont., Can.

JESSIE LEES.

HONEY CRUSTS.

Trim and butter 6 half-slices of stale bread, and arrange them in a buttered baking-dish. Core three large juicy tart apples and halve them crosswise. Lay them on the board; cut side down and fill to overflowing with a mixture of honey and nuts, lightly salted. Bake half an hour, or until the crusts are brown, crisp, and sugary, and the apples brown, tender, and foamy. Serve hot or cold with whipped cream. Butternuts and Brazil nuts are particularly good.

R. F. D.

HONEY RUSKS.

Three cupfuls of flour; 2 cupfuls of milk; 1-3 cupful of honey, or more, according to taste; one cake of compressed yeast dissolved in $\frac{1}{2}$ cupful of warm water; $\frac{1}{4}$ teaspoonful of salt. Mix thoroughly, and set in a warm place to rise. When very light add a beaten egg, 3 tablespoonfuls of melted butter, and flour for a soft dough—about a cupful. Knead lightly, and mold in small biscuits or twists. Raisins, currants, or cardamom seed may be added at discretion. Rub the top with beaten egg; cover, and let it rise again until they double in bulk, and are very light and fluffy. Bake 20 to 25 minutes in a moderate oven, glazing them with sugar and water just before removing from the oven.

Honey Rusks, or Sweet Biscuit. Recipe by Rachel F. Dahlgren.

R. F. D.

A LAXATIVE DRINK.

A very wholesome and refreshing drink is made by dissolving a level teaspoonful of pure cream tartar in a little boiling water, adding a tablespoonful of honey, and filling up the glass with cold water, or hot water where a hot drink is preferred. This is especially good in case of a feverish cold.

R. F. D.

DAFFODIL MERINGUE.

Moisten 2 tablespoonfuls of granulated tapioca with cold water and stir it into a pint of boiling water. Salt lightly, and cook until clear. Beat the yolks of 2 or 3 eggs, and beat in $\frac{3}{4}$ cupful of honey with 2 tablespoonfuls of lemon juice and one tablespoonful of butter. Add this gradually to the tapioca, and cook over hot water until it thickens—about 20 minutes. Pour into a buttered dish, adding a little candied lemon-peel if you like. Cover with a meringue made of the white of egg beaten with 2 or 3 tablespoonfuls of honey, and bake to a delicate fawn color.

R. F. D.

HONEY MOUSSE.

Peel and cut up two oranges, rejecting the white inner skin; soak a teaspoonful of powdered gelatine in a tablespoonful of water. Heat one cupful of thick honey over boiling water. Add the orange and gelatine, and stir for five minutes; then remove it from the fire, and when cold add a pint of thick cream whipped stiff. Pack in ice and coarse salt (equal quantities), and let it stand for three or four hours. Pineapple or other fruit may be used instead of orange. This is easy to make, requires no freezer, and the result is delicious.

R. F. D.

FIP TOP LEMON PIE.

Yolks of 3 eggs beaten light; one small cupful of honey; one tablespoonful of flour; juice, flesh, and grated rind of one lemon; one teaspoonful of melted butter. Mix thoroughly in the order given, then add $1\frac{1}{4}$ cupfuls of rich milk; pour into a pie-plate lined with a good crust, pricked to prevent air blisters, and bake until set. Cover with a meringue of the whites, beaten with 3 tablespoonfuls of honey, and a few drops of lemon juice, and brown lightly.

R. F. D.

[After trying this recipe it seemed to us that it was a little too "wet." We would suggest that only half a cupful of honey be used, and half a lemon. Of course, tastes differ. Perhaps many would prefer the recipe as originally given. We baked

the crust separately, and also cooked the filling in a double boiler before putting it in the shell.—Ed.]

IVORY CREAM.

One tablespoonful of granulated gelatine; $\frac{3}{4}$ cupful of honey; 2 cupfuls of milk; one cupful of thin cream; one cupful of peaches or other fruit; $\frac{1}{2}$ teaspoonful of bitter almond. Warm the milk, cream, and honey together, but do not scald them. Add the gelatine, which has been soaked in milk for a few minutes, and the almond extract. Stir till the gelatine is dissolved, and set it in a cold place until it begins to stiffen; then add the peaches, peeled and cut fine. Mix lightly, and pour into a wetted mold. Bananas or canned peaches may be used when the fresh fruit is not in season. Decorated with split almonds, and served with whipped cream, this is a dessert worthy of any occasion.

Redding, Ct.

RACHEL F. DAHLGREN.

HONEY COOKIES.

Cream half a cup of butter; beat in $\frac{3}{4}$ of a cup of sugar; one egg and one yolk beaten together; half a cup of strained honey, the grated rind of a lemon, and three cups of flour sifted with four teaspoonfuls of baking-powder. More flour may be required. The dough should be firm enough to be easily handled; knead slightly (a little at a time); roll into a thin sheet, and cut into cakes. Set the shapes in a buttered pan. Beat the white of an egg (left for the purpose) a little, and use it to brush over the cookies in the pan; then at once sprinkle with fine chopped blanched almonds, and dredge with granulated sugar. Bake in a moderate oven.

MRS. O. C. HINMAN.

Silver City, N. M.

HONEY COOKIES.

One cup shortening (butter and lard); one cup honey; one cup brown sugar; 2 eggs; one tablespoonful of soda dissolved in 6 tablespoonfuls of sweet milk; 2 tablespoonfuls of vinegar; 2 teaspoonfuls ginger; one teaspoonful salt. Add flour to make a soft dough. Roll thin.

Owosso, Mich.

FLORENCE M. GALLAGHER.

HONEY GINGER SNAPS.

Take one pint of honey, one teaspoonful of ginger, and one teaspoonful of soda dissolved in a little water and two eggs. Mix all, and work in all the flour possible. Roll very thin, and bake in a moderately hot oven. Any flavoring extracts can be added as desired.

Fresno, O.

LILLIAN PIGMAN.

Honey drop cakes. Recipe by Martha W. Dewees.

HONEY DROP CAKES.

One cup sugar; one cup shortening ($\frac{1}{2}$ butter, $\frac{1}{2}$ lard); 1-3 cup buttermilk or sour cream; 2 tablespoonfuls extracted honey; 2 or 3 eggs well beaten; $\frac{1}{4}$ teaspoonful soda; one teaspoonful baking-powder; $\frac{1}{2}$ teaspoonful vanilla, orange, or lemon as suits the taste. Flour to make a very stiff batter to drop from a spoon on greased pan, and bake in a moderate oven. These will run together on baking, and must be cut apart with a knife, but are much better than rolled, besides being less trouble. This is a well-tested recipe, and pronounced excellent by all who have tried it.

Barnesville, O.

MARTHA W. DEWEES.

[We find that it requires $3\frac{1}{2}$ cups of flour for the drop cakes. This recipe also makes an excellent cake if 3 cups of flour are used and only 2-3 cup shortening.—Ed.]

HONEY FRITTERS.

Take $1\frac{1}{2}$ cupfuls of sifted flour; 2 tablespoonfuls honey; 2 teaspoonfuls baking-powder; one egg; $\frac{1}{4}$ teaspoonful salt; 2-3 cupful milk; 2 tart apples. Mix and sift the dry ingredients and stir into them the beaten egg with which the milk and honey have been mixed. Pare and core the apples; cut into rings or dice, and dip into the batter. Fry in deep hot fat, drain, and sprinkle with pulverized sugar if desired.

HONEY CORNSTARCH PUDDING.

Take 1 cupfuls scalded milk; $\frac{1}{4}$ teaspoonful salt; 1-3 cup honey; $6\frac{1}{2}$ tablespoonfuls cornstarch. Mix the honey, salt, and cornstarch. Stir in the hot milk gradually, stirring until smooth. Stir and cook over boiling water until the mixture thickens. Cover and cook 15 minutes. Turn into a wet mold; chill, and serve with cream and sugar.

Honey cornstarch pudding. Recipe by Mrs. Henry V. L. Hooper.

STEAMED SUET PUDDING.

Take 3 cupfuls sifted flour; $\frac{1}{2}$ teaspoonful nutmeg; 4 teaspoonfuls baking-powder; one teaspoonful cinnamon; $1\frac{1}{2}$ teaspoonfuls salt; $\frac{1}{2}$ teaspoonful ginger; $\frac{1}{2}$ teaspoonful cloves; one cupful finely chopped suet; one cupful milk; one cupful honey; one cupful chopped raisins. Mix and sift the dry ingredients, and add the suet and raisins. Add the honey to the milk, and stir into the dry mixture. Turn into a buttered mold and steam 3 hours. Serve hot with sauce.

COFFEE CAKE.

Take $2\frac{1}{4}$ cups of sifted flour; 3 tablespoonfuls of honey; 3 teaspoonfuls of baking-powder; 4 tablespoonfuls of butter; $\frac{1}{2}$ teaspoonful of salt; milk; one egg. Mix and sift the dry ingredients and rub in the butter. Beat the eggs; add enough milk to make $1\frac{1}{4}$ cups, and stir in the honey. Stir the liquid mixture into the dry mixture. Turn out into a shallow buttered pan; brush the top with melted butter; sprinkle with 3 tablespoonfuls of sugar mixed with $\frac{1}{2}$ teaspoonful cinnamon, and bake in a moderate oven.

SCALLOPED APPLES

Take 3 cupfuls soft stale bread-crumbs; $\frac{1}{4}$ cupful honey; $\frac{1}{4}$ cupful butter; $\frac{1}{4}$ teaspoonful grated nutmeg; one quart sliced apples; grated rind, and juice of $\frac{1}{2}$ lemon. Melt butter, and stir lightly into the bread-crumbs. Cover the bottom of the buttered pudding-dish with crumbs, and spread over one-half the apples. Cover with half the honey, nutmeg, lemon juice, and rind mixed together; repeat, cover with the remaining crumbs, and bake 40 minutes in a moderate oven. Cover at first to prevent the crumbs browning too rapidly. Serve with sugar and cream.

NEW ENGLAND PUDDING.

Take one cupful of tapioca; $\frac{1}{2}$ teaspoonful salt; 3 cupfuls boiling water; $\frac{1}{2}$ cup honey; 2 tablespoonfuls butter; 6 tart apples. Soak tapioca in cold water one hour. Mix the soaked tapioca with a little cold water, and stir into boiling salted water. Cook over boiling water until transparent. Pare, halve, and core the apples, and place in a buttered baking dish. Cover with honey and dot with butter. Pour the tapioca over the apples and bake in a moderate oven until the apples are soft. Serve with cream and sugar.

HONEY GINGERBREAD

Take $\frac{1}{2}$ cupful lard or butter; 3 cupfuls sifted flour; $\frac{1}{2}$ cupful hot water; one teaspoonful soda; one cupful molasses; two teaspoonfuls ginger; $\frac{1}{2}$ cupful honey; one teaspoonful cinnamon; 1 egg; $\frac{1}{4}$ teaspoonful cloves. Melt the fat in the hot water,

and add the molasses, the honey, and the beaten eggs. Add the mixed and sifted dry ingredients and bake in a cool oven.

CORN BREAD.

One cup sifted flour; $\frac{1}{2}$ teaspoonful salt; one cup corn meal; 2 tablespoonfuls melted butter; 3 tablespoonfuls honey; 2 eggs; 3 teaspoonfuls baking-powder; one cup milk. Mix and sift the dry ingredients. Beat the eggs; add the milk, the honey, and the melted butter, and combine with the first mixture. Bake in a shallow pan or muffin tins.

HONEY MUFFINS.

Three and one-half cupfuls of sifted flour; 3 tablespoonfuls honey; one teaspoonful salt; 6 tablespoonfuls melted butter; 5 teaspoonfuls baking-powder; 2 eggs; $1\frac{1}{2}$ cupfuls milk. Mix and sift the dry ingredients. Beat the eggs, add the milk, the honey, and the butter, and combine the two mixtures. Put into buttered muffin-tins and bake 20 minutes in a moderate oven.

CORN GRIDDLE-CAKES.

Take 2 cupfuls of corn meal; $\frac{1}{4}$ cupful of honey; one cupful of sifted flour; 2 eggs; $\frac{1}{2}$ teaspoonful of salt; $2\frac{1}{2}$ cupfuls of milk; three teaspoonfuls of baking-powder; 2 tablespoonful melted butter. Mix and sift the dry ingredients. Beat the eggs, add the milk, the honey, and the melted butter, and combine with the first mixture. Bake on a well-oiled griddle.

HONEY RICE PUDDING.

Take 2 cupfuls boiled rice; $\frac{1}{2}$ cupful honey; $1\frac{1}{2}$ cupfuls milk; $\frac{1}{2}$ cupful raisins; one beaten egg; a pinch of salt and cinnamon. Mix all the ingredients but the cinnamon. Put into a buttered baking-dish; sprinkle with the spice, and bake in a moderate oven until thick and brown. Serve cold.

Johnstown, Pa. MRS. HARRY V. L. HAGAR.

I live on a farm, as many other beekeepers do, and I like to cook with cream instead of butter, as it is much more wholesome, and with honey instead of sugar. So I have to change the cook-book recipes to suit myself.

SALAD DRESSING.

Take yolks of 2 eggs; 2 tablespoonfuls of honey; one tablespoonful of salt; $\frac{1}{2}$ cup olive oil; lemon juice or honey vinegar (weak). Beat together the yolks, honey, and salt. Add a few drops of oil at a time, beating constantly until the oil is all added. Thin down to the desired consistency with lemon juice or weak honey vinegar.

HONEY CANDY.

Take 2 cups of sugar; $\frac{1}{4}$ cup honey; $\frac{3}{4}$ cup thick cream. Put the ingredients into a sauce-pan; stir till dissolved, then boil without stirring till a hard ball is formed when tried in cold water. Remove from the fire. Beat till thick; pour into a buttered plate and cut into squares.

HONEY "BROWN BETTY" PUDDING.

Take 4 cups raw apple cut fine; 2 cups bread crumbs; $\frac{1}{2}$ cup each of honey and hot water; 2 teaspoonfuls of butter or cream; cinnamon. Put a layer of the apple in a well buttered pudding-dish; then a layer of crumbs. Mix the honey and hot water. Pour part of it over the crumbs and add a sprinkling of cinnamon, and a few dots of butter or thick cream. Add another layer of apple, and so on until the dish is full, with crumbs on top. Cover,

Honey oatmeal cookies. Recipe by Mrs. A. S. Bradley.

and bake 45 minutes. Eat with sauce of $\frac{1}{2}$ honey and $\frac{1}{2}$ cream.

HONEY OATMEAL COOKIES.

One cup of honey; one of rich sour cream; 2 eggs; 2 cups of rolled oats and 2 cups of flour; one tablespoonful of grated chocolate or cocoa; one teaspoonful of soda; $\frac{1}{2}$ teaspoonful each of cinnamon, cloves, nutmeg, and salt; one cup of chopped raisins; $\frac{1}{2}$ cup of chopped nuts (if desired). Sift the dry ingredients together (except the rolled oats); add all other ingredients. Stir well, and drop by teaspoonfuls in cooky-pans, or bake in gem-pans.

HONEY GINGERBREAD.

One cup honey; $\frac{3}{4}$ cup rich sour cream; $\frac{1}{2}$ cup molasses; $1\frac{1}{2}$ teaspoonfuls ginger and one teaspoonful each of soda and salt; 3 cups of flour; 2 eggs. Sift the dry ingredients together; add all the rest, and beat well. Bake in a flat pan or in gem-pans.

BAKED APPLES.

Take 6 apples; one cup each of cream and honey. Mix the cream and honey. Dig out the core of each apple from one end, leaving the other end closed. Fill the holes with the honey-and-cream mixture. Bake with a little water in the bottom of the pan. Use the rest of the honey-and-cream mixture as a sauce to eat on the apples.

Locke, Wash.

MRS. A. S. BRADLEY, JR.

HONEY COOKIES.

One cup of granulated sugar; one cup of boiling water; one cup of lard or butter; one cup of honey; two teaspoonfuls of cinnamon; one teaspoonful ginger; one teaspoonful of soda with enough water to dissolve. Put all the above, except water, in flour, and pour the one cup of boiling water over it and mix it until as stiff as biscuit dough. Roll out thin and cut into cookies, and bake in a quick oven.

Watseka, Ill.

MRS. J. H. GILLAN.

For some time we have been using honey in place of molasses, and find it superior. In baking apples we fill the centers with honey, which gives them a finer flavor. One of our neighbors makes her apple jelly with honey, and it is very nice, both in color and flavor.

Served with fresh dewberries and peaches, it makes a delicious dessert, as it imparts a much richer flavor than sugar. We are going to can our peaches with honey this fall.

In making fruit cake, mince meat, gingerbread, plum pudding, and brown bread it is superior to molasses.

Cookies and cake keep moist longer made with honey than with sugar, which is an advantage in this dry climate.

Loma, Col.

MISS FORREST BOYD.

Peaches, pears, apricots, prunes, and strawberries are never canned any other way at our house than with honey. Cooking with honey is my hobby, as I am ever experimenting with new recipes.

GRAHAM PUDDING

Take $\frac{1}{4}$ cup butter; 2-3 cup strained honey; $\frac{1}{2}$ cup milk; one egg; $1\frac{1}{2}$ cups graham flour, $\frac{1}{2}$ teaspoonful soda, one teaspoonful salt; one cup seedless raisins. Melt the butter; add honey, milk, and egg, well beaten; dry ingredients mixed and sifted, and raisins; turn into buttered mold; cover, and steam $2\frac{1}{2}$ hours. Serve with pudding sauce.

CANNING FRUIT WITH HONEY.

Prepare your fruit as usual for canning, in the way of paring, hulling, etc. Put on to boil. When it is done ready for canning add your honey, about two-thirds as much as you would sugar (this is according to your own taste, as some prefer it sweeter than others). [We have always used the same amount as formerly used of sugar.—Ed.] Have your jars ready, clean, and very hot. Now put in your fruit and seal. Be sure to let the fruit just come to the boiling-point. After adding your honey, *do not boil*, as this spoils your fine flavor. Fruit canned thus keeps as well as if not better than by the old method of canning with sugar; and when once tried no other way will be used.

HONEY COOKIES.

Two eggs, half a cup sugar, 2 cups extracted honey, one cup of boiling water in which dissolve a teaspoonful of soda; any flavoring or spice desired. Flour to mix very stiff. Mix in the order given; roll out and bake. These are hard when first baked, but keep in a tight jar or box a few days and they are fine.

HONEY CAKE.

One egg, one cup sugar, one of sour cream; one cup buttermilk; 3 cups extracted honey; one teaspoonful salt; $\frac{1}{2}$ teaspoonful each of ginger, cinnamon, and cloves, one heaping teaspoonful of soda; $3\frac{1}{2}$ cups flour. Mix the egg, sugar, honey, cream, and buttermilk in order given; sift other ingredients with the flour; mix and bake in a pan lined with greased paper in a rather slow oven. The addition of fruit to this makes a fine fruit cake.

Graham pudding. Recipe by Mrs. Homer Cheney.

HOT-WATER HONEY CAKE.

Take $\frac{1}{2}$ cup sugar; one tablespoonful lard; $1\frac{1}{2}$ cups of honey; one teaspoonful of any spice or flavoring desired; $\frac{1}{2}$ teaspoonful salt; $2\frac{1}{2}$ cups flour. Mix in order given, and, lastly, add one cup of boiling water in which dissolve a heaping teaspoonful of soda. Beat well; turn into a well-greased pan and bake in a moderate oven. This is fine, and is a great favorite at our house.

RED-CURRENT JELLY

Stem and clean red currants; heat slowly, and extract the juice. Put back on the stove, after measuring, and let it boil 20 minutes. To every pint of juice add a scant cup of sugar and $\frac{1}{2}$ pint of extracted honey. Let it boil a few minutes till ready to jell, which will be in about ten minutes. You can tell by taking a little out in a sauce-dish and cooling it. Then turn into jelly-glasses, and you have something fine.

New Plymouth, Ida. MRS. HOMER CHENEY.

Apple pudding. Recipe by Iona Fowls.

HONEY HERMITS.

One cup butter; $1\frac{1}{2}$ cups warm honey in which is dissolved a teaspoonful of soda; 3 eggs well beaten; 3 cups flour, one teaspoonful salt, 2 teaspoonfuls cinnamon sifted together; $2\frac{1}{4}$ cups raisins, chopped, $2\frac{1}{4}$ cups chopped nut meats. Drop by teaspoonfuls, and bake in a moderate oven.

LEMON CRUMBE PIE.

One cup buttered bread crumbs; $\frac{1}{2}$ cup honey; 2 yolks and the white of an egg; pinch of salt; one cup cold water into which is dissolved a tablespoonful of cornstarch, level; juice and rind of one lemon. Fill crust, and bake. When done, cover with meringue.

LADY FINGERS.

Beat together one cup honey, warmed, $\frac{1}{2}$ teaspoonful baking-powder, $\frac{1}{2}$ teaspoonful soda; $\frac{1}{2}$ cup butter; one teaspoonful salt, level; 2 eggs well beaten; 4 cups flour. Cut in little strips; roll in sugar, and bake in a quick oven.

NUT BREAD.

Take 2 compressed yeast cakes; 1-3 cup warm honey; $\frac{3}{4}$ cup lukewarm scalded milk; 3 cups flour; 2 tablespoonfuls butter; white of an egg, beaten; one cup chopped nuts; 2 teaspoonfuls salt. After dissolving the yeast cakes in the warm milk, stir in a tablespoonful honey and $1\frac{1}{2}$ cups of flour, beating all thoroughly. Then place in a warm place to rise. When light, add the remainder of the honey and flour and the rest of the ingredients. Knead well and place in a greased bowl and let it rise until double in bulk. Then make into a loaf; and, when light enough, bake in a slow oven.

APPLE PUDDING.

Apples sliced fine; $\frac{1}{4}$ cup honey; cinnamon; butter; one cup rice, cooked for several hours; one egg beaten into the rice; one teaspoonful salt; $\frac{1}{2}$ cup water; 3 or 4 slices bread (crumbed). In the bottom of the pan place a layer of crumbs with dots of butter here and there; then a layer of apples, with honey and cinnamon on top. The third layer is the mixture of rice, egg, and salt. The fourth and fifth layers are a repetition of the first and second. Add $\frac{1}{2}$ cup water and bake in a moderate oven. When done, cover with meringue. [In following

this recipe we used the yolks of two eggs instead of one whole egg, as given, saving the whites for the meringue. Ed.]

APPLE SAUCE CAKE.

Take $\frac{1}{2}$ cup butter; $\frac{3}{4}$ cup honey if apples are mild; but if the apples are sour, use $1\frac{1}{4}$ cups honey; $\frac{3}{4}$ cup apple sauce; one teaspoonful soda; the soda should be well beaten into the sauce; 2 cups flour; $\frac{1}{2}$ cup raisins; one teaspoonful each of cinnamon, cloves, and nutmeg.

Oberlin, O.

IONA FOWLS.

CHOCOLATE NOUGATINES.

One cup granulated sugar; 1-3 cup glucose; 1-2 cup extracted honey; piece of paraffin, size of a pea; $\frac{1}{4}$ cup of water; $\frac{1}{4}$ teaspoonful of salt; whites of

Chocolate nougatines. Recipe by
Frank Quackenbush.

2 eggs beaten dry; one cup English-walnut meats chopped fine; one teaspoonful vanilla; $\frac{1}{2}$ lb. Baker's chocolate. Put the sugar, glucose, honey, paraffin, and water over the fire; stir occasionally, and let it boil to the hard-ball degree. Add the salt to the eggs before beating them, and gradually pour on part of the syrup, beating constantly with an egg-beater. Return the rest of the syrup to the fire, and let it boil until brittle when tested in water. Then gradually turn it on to the eggs, beating constantly. Return the whole to the sauce-pan; set over the fire on an asbestos mat, and beat constantly until it crisps when tested in cold water. Pour into a buttered pan; set it aside to cool; cut in squares, and dip in melted chocolate.

HONEY AND NUT SANDWICHES.

Mix one cup of honey with 2 teaspoonfuls of lemon juice; then stir in enough finely chopped nuts to make a stiff paste; spread on slices of buttered bread.

HONEY CANDY.

One quart honey; 3 heaping tablespoonfuls of butter; 2 tablespoonfuls of vinegar; $\frac{1}{2}$ teaspoonful soda; 2 teaspoonfuls lemon extract. Boil the honey, butter, and vinegar until it hardens when dropped into water; stir in soda and extract; pour into buttered tins to cool.

Hebron, O.

FRANK QUACKENBUSH.

STEAMED GRAHAM PUDDING.

Half a cup of honey; one cup raisins; one cup graham; one teaspoonful each of cinnamon, cloves, ground; nutmeg; $\frac{1}{2}$ cup salt; one cup of soda in half a cup of boiling water. Turn in well-greased pudding-pan and steam $1\frac{1}{2}$ hours.

LEMON SAUCE FOR GRAHAM PUDDING.

One lemon rind grated, and juice squeezed on one cup of sugar; one egg and a spoonful of butter; small pinch of salt. Boil, and serve hot.

RED BLACK FRUIT CAKE.

One pound each of raisins, currants, and butter; 4 eggs; teaspoonful of cinnamon, one cup of sour

milk; one teaspoonful cloves, one cup of honey, one teaspoonful nutmeg, 2 cups brown sugar, one teaspoonful allspice; 2 teaspoonfuls soda; flour to make a heavy batter. Bake in a slow oven one hour.

HONEY VINEGAR.

Pour one pint of strained honey in a gallon jug, and fill the jug with clear rain water. Tie cloth over the top, and keep warm.

Durand, Ill.

ADDIE WESTBROOK.

BOSTON BAKED BEANS.

Look over one quart of dried beans. Soak them in cold water over night. Drain the water off and put on to parboil, adding hot water and a pinch of soda. When the hull begins to break, drain. Then if you have a bean-pot or roaster pour the beans in it and add a teaspoonful of salt; one tablespoonful of tomato catsup; or, if you prefer mustard, use that. Add three tablespoonfuls of extracted honey. Cover the beans with hot water; season with pepper; then place on top three or four slices of pickled pork or breakfast bacon, and bake in moderate oven three hours or until the beans have taken on a rich brown color.

BAKED SQUASH.

Peel and slice your squash the same as you would large sweet potatoes—say half an inch thick. I use a large granite bread-pan for cooking the squash. Place slices in the bottom of the pan. Dot each slice with a generous piece of butter; strew honey over the squash, say a teaspoonful to each slice; then pour in hot water enough to cover the bottom of the pan. I first start the cooking on top of the range. After it has boiled well for, say, ten to fifteen minutes, turn each slice with a knife, and boil until tender. You may possibly have to add a little more hot water. You can now place the pan in the oven and let the squash take on a delicate brown. Serve at once after removing from the pan.

If you have never eaten baked squash prepared in this way, try it. We prefer it to sweet potatoes, and it is much more easily digested.

Washington, Ind.

MRS. S. H. BURTON.

FRUIT CONFECTION.

One pound of dried figs; $\frac{1}{2}$ pound each of dried peaches, prunes, and raisins; one cup of honey; one cup of chopped nuts. Run the fruit through a meat-chopper; mix in the honey and nuts, and knead; press into a form; cut in squares; roll in powdered sugar, and serve.

Phoenix, Ariz.

MRS. JENNIE C. GIBSON.

HONEY CAKES.

One quart honey (warm); $\frac{1}{4}$ lb. butter (warm); one cup sour milk (thick); yolks of 3 eggs; 1 oz. baking-soda; $\frac{1}{2}$ teaspoonful powdered alum; $2\frac{1}{2}$ lbs. flour. Mix, and let stand from two days to two weeks; roll out thin, and bake. Frost, when cold, with pulverized sugar moistened with a little milk.

Council Bluffs, Ia.

MRS. J. B. KOUPAL.

SPICE CAKES.

One pint molasses; one pint strained honey; 12 oz. butter and lard; 12 oz. of brown sugar; 1 oz. soda; 1 oz. ginger; 1 oz. cinnamon; $\frac{1}{2}$ oz. cloves; 4 lbs. flour; stir the soda in tablespoonful of milk, and add last.

Watseka, Ill.

CLARENCE SCHOLL.

CUCUMBER PICKLES.

Two quarts of small cucumbers; one quart of vinegar; one lemon, one cup of honey (extracted).

Wash and soak the cucumbers in salt water 24 or more hours— $\frac{1}{2}$ cup of salt to a gallon of water; then drain, put the vinegar in granite kettle or pan; bring to the boiling-point; add the honey and lemon; grate the rind of it, and put in the vinegar. Then squeeze the juice and add it to the vinegar; also drop in the cucumbers and boil twenty minutes,

stirring them occasionally, then put all in glass jars and seal.

Buckley, Wash.

CAROLINE J. SWOPE.

WHOLEWHEAT BREAD, WHICH CONTAINS ALL THE VITALIZING ELEMENTS OF THE GRAIN.

One quart whole-wheat flour, full measure (may be made $\frac{1}{2}$ graham or 1-3 rye); one pint water (may be made $\frac{1}{2}$ scalded milk, cold. This gives the bread a finer texture, and a flavor which may not please all); one large cooking-spoon (overflowing) of honey; $\frac{1}{2}$ compressed yeast cake, or the equivalent—the more yeast, the quicker the rising; 1 $\frac{1}{2}$ teaspoonfuls salt, medium-sized spoon, plump measure. Salt has a retarding effect upon fermentation, depending on the relative quantity. Have the water slightly warm in cold weather and cool in hot weather. Dissolve the yeast thoroughly in the water; add the honey; mix well, add the salt, stir until dissolved. A yellow-ware bowl is most convenient. Mix the flour and water perfectly by means of a

30 to 35 minutes in an oven not too hot. This bread does not become stale for several days if kept as other bread; but in our house it never has time to get stale or dry.

This recipe is not entirely original; but the addition of graham or rye, and the substitution of honey for sugar, are my own, and have been thoroughly proven. It may be well to add that the bread is not sweet from the use of honey (or sugar) when mixing the flour, water, etc. However, when rye is added, the bread is rather more inclined toward sweetness, probably because the fermentation is not carried forward as rapidly nor so far as to decompose the honey entirely. There is a natural flavor to the whole wheat flour which might be described as "sweet," and it may be that this natural flavor is more noticeable when mixed with rye, which is never sweetened.

I have tried sugar in place of honey, but it has been voted not nearly as good in flavor or texture. Hoboken, N. J. C. D. CHENEY.

HONEY DROP CAKES

Take 2 $\frac{3}{4}$ cups flour; 1 teaspoonful of baking-powder; one tablespoonful baking soda; 2 teaspoonfuls boiling water; one egg; one cup of honey; $\frac{1}{2}$ cup of crab-apple jelly; $\frac{1}{2}$ cup of butter. Cream the butter; add the jelly, and beat well. Dissolve the soda in the boiling water; beat the egg, and add, beating again; then the honey; and, lastly, stir in the flour sifted with the baking-powder. Drop by the teaspoonful on baking sheet, and bake in a slow oven until brown.

HONEY FRUIT BREAD.

Take 4 cups of flour; 1 cup brown sugar; 2 rounding teaspoonfuls of baking-powder; 3 eggs; $\frac{1}{2}$ cup of butter; 5 tablespoonfuls of honey; one cup of mixed candied fruits, cut up; one tablespoonful of candied ginger, cut up; $\frac{1}{2}$ cup of citron, cut up; 4 tablespoonfuls of orange juice; 4 tablespoonfuls milk. Sift the flour and baking-powder together; add the citron, mixed fruits, and ginger; cream the butter and sugar together; add one of the eggs, well beaten, and 3 tablespoonfuls honey, and

beat well. Beat the two remaining eggs, and add it with remaining 2 tablespoonfuls of honey, and beat again. Stir in the orange juice; sift the baking-powder with the flour, and add alternately with the fruit, which has been previously dredged with flour. Mix well, and bake in a greased loaf-tin in a slow oven for about an hour.

HONEY GINGER BREAD.

Take $\frac{1}{2}$ cup of butter; one cup of raisins; $\frac{3}{4}$ cup of honey; $\frac{1}{2}$ cup of chopped citron; $\frac{1}{4}$ cup of milk; one cup of candied cherries, cut up; 2 eggs; one rounding teaspoonful of baking-powder; $\frac{1}{4}$ teaspoonful of salt; 5 cups flour; one teaspoonful of ginger. Warm the butter, honey, and milk over a slow fire; cool, and add the well-beaten eggs, the salt, and the ginger. Sift the baking-powder with

Pears canned without sugar. Only those who regularly use honey in canning and preserving can appreciate the rich flavor and the fresh natural color of the fruit thus prepared. And, best of all, the fruit keeps better than when canned with sugar.

large cooking-spoon, putting all together at once. The dough should be rather sticky and soft. If the dough is too stiff with the pint of water, more may be added, a teaspoonful or two at a time thoroughly incorporated, until the right consistency is attained. If the bread is wanted rather dry, leave the dough stiffer. Cover closely, keeping in a warm place in cold weather, and *vice versa*. In the morning turn the dough out on the board, and knead into it butter the size of an egg, flouring the board and hands as lightly as possible. The butter may be omitted, but it is a great improvement. Make two loaves in narrow pans; cover, and keep warm to rise. It should about double in bulk. If the dough is not covered closely the surface will dry so as to form a skin. This will cause streaks in the bread. Bake

the flour; dredge the fruit with flour, and add these alternately. Mix well, and bake in a greased loaf-pan about an hour.

East Orange, N. J.

Mrs. A. F. ROLF.

HONEY CAKE.

Honey, one cup; $\frac{1}{2}$ cup shortening; 1 use drippings; one egg; one cup milk, warmed; 2 cups flour; one heaping teaspoonful of soda; $\frac{1}{2}$ teaspoonful cream of tartar; $\frac{1}{4}$ teaspoonful salt. Sift the flour, soda, cream of tartar, and salt together three times. Stir the honey and shortening to a cream; break the egg in this, and beat thoroughly with spoon; then half the milk and half the flour alternately; beat well each time you add milk or flour. This makes a very soft dough, but is much more delicate so, and is very nice if warmed for luncheon. Bake in a moderate oven $\frac{3}{4}$ of an hour to an hour.

New Hampton, N. Y.

MARY HOWELL.

PRESERVED CANTALOUPE.

Honey, 1 lb.; cantaloupe, 1 lb.; bring the honey to a boiling-point, and drop in the prepared cantaloupe, which should be cut in thin slices.

Bunceton, Mo.

J. R. MARYE.

FRUIT SALAD.

Cut one cup each of banana and orange; pit a cup of cherries; stir up with $\frac{1}{2}$ cup of honey, extracted; garnish with slices of comb honey, and serve. Puffed rice, boiled rice, or boiled pearl barley can be added if desired.

Buckley, Wash.

CAROLINE J. SWOPE.

PEANUT COOKIES.

One cup chopped peanuts; mix and sift 3 cups of flour, $\frac{1}{2}$ teaspoonful salt, one scant teaspoonful soda, then add a cup of brown sugar, one cup strained honey; then add $\frac{3}{4}$ cup melted lard, 2 eggs well beaten, $\frac{1}{2}$ cup sour cream, one teaspoonful vanilla; add the nuts. Bake in a moderate oven, dropped from a spoon in a well-greased pan.

Laurel Springs, N. C.

Mrs. C. A. REEVES.

HONEY PUDDING.

Take a cup of toasted bread crumbs rolled fine; one quart milk; one teaspoonful soda; one cup honey; one cup raisins; half a teaspoonful each of cinnamon and nutmeg; 3 eggs and a small spoonful of butter. Steam or boil from $1\frac{1}{2}$ to 3 hours. Serve with any sauce desired.

Caldwell, Ida.

Mrs. CECIL LAPPIN.

DELICIOUS BAKED BEANS WITH HONEY.

Cook a quart of navy beans until tender; season with salt and pepper to suit your taste, then put on one heaping tablespoonful of lard and 4 level tablespoonfuls of honey, and bake one hour.

HONEY COOKIES.

One pint thick cream; one pint butter; 3 eggs; 2 teaspoonfuls soda; 3 coffee-cups of honey; flour enough to make stiff enough to handle, being careful not to get too stiff. These are fine, and will keep good for more than a month.

APPLE AND PLUM SAUCE WITH HONEY.

Cook apples well done, and sweeten with honey to suit taste.

Cook plums in a syrup made of equal parts of sugar (granulated) and honey.

Huntington, Ind.

Mrs. E. H. UPSON.

NORWEGIAN HONEY CAKE.

Take 9 eggs; 1 lb. sugar; 1 lb. honey; $\frac{1}{2}$ teaspoonful baking soda; $\frac{1}{4}$ lb. or a little more of citron; one teaspoonful cloves; $\frac{1}{2}$ teaspoonful pepper; one teaspoonful ginger; 1 lb. flour. Beat the eggs and sugar well. My cook-book says one hour. Add the honey, which must be slightly warm; then the spices, then the citron cut fine, and, last, the well-sifted flour. The soda can be dissolved in a

teaspoonful of warm water, or sifted with the flour. This makes a large cake, and must bake $1\frac{1}{2}$ hours in an oven not too hot. It will keep for months. Grease the pan well.

Fairhope, Ala.

Mrs. W. A. FERMANN.

Honey doughnuts. Recipe by Julia A. Corbett.

HONEY DOUGHNUTS.

Take 2 eggs; one cup buttermilk; 1 cup sugar; one cup honey; one teaspoonful soda and 2 of cream tartar; butter size of an egg; one teaspoonful vanilla; flour to make stiff enough to roll. The honey added to this recipe makes the doughnuts a delicious brown, and also makes them keep moist for a much longer time.

HONEY-CURED HAM OR BACON.

To 100 lbs. of meat allow 10 lbs. salt, 2 ounces saltpeter, one ounce cayenne pepper, one quart honey, 8 gallons soft water; boil and skim; pour this on the meat when cool. When you hang it up to dry take sufficient honey and ground spices to make a stiff paste. Rub this well into the meat; and, after allowing it to penetrate from 4 to 6 inches, wash off and dry. Hams and bacon cured this way will be found particularly wholesome. I have followed this method for several years with the best results.

Amherst Point, N. S.

JULIA A. CORBETT.

HONEY GINGER CAKE.

Heat one cupful of extracted honey, and just before it reaches the boiling-point remove it from fire. Then add a teacupful of thin sour cream, two well-beaten eggs, half a teaspoonful each of salt, ginger, and cinnamon; one heaping teaspoonful of soda, and three scant cupfuls of sifted flour. Beat well, then flour half a cupful of seeded raisins, and stir in lightly. Bake in a moderate oven.

Osceola, Neb.

Mrs. W. A. CARNINE.

SWEET CUCUMBER PICKLES.

To one quart cucumbers take 2 cups of vinegar, one cup of honey, and a few mixed spices; let come to a boil, then pour over cucumbers and seal.

HONEY DROP COOKIES.

Take 2 cups of brown sugar; $\frac{1}{2}$ cup melted lard; 2 eggs; one cup cold water; $\frac{1}{2}$ cup honey; one cup raisins; one teaspoonful salt; one teaspoonful cloves; two teaspoonfuls cinnamon; two teaspoonfuls soda dissolved in a little cold water; 6 cups flour, or enough to make the dough stiff. Drop by teaspoonful on greased tin, and bake in a quick oven.

Fairfax, Ia.

Mrs. C. F. WIENEKE.

RAISIN HONEY PIE.

Cover a cup of seeded raisins with water, and stew until tender. Add $\frac{1}{2}$ cup of honey, one tablespoonful of butter, one tablespoonful of flour; beaten

yolk of one egg. Pour in pie plates lined with any good pie paste, and bake. Beat the white of the egg to a stiff froth; add $\frac{1}{4}$ cup of sugar spread over the top of the pie, and return to the oven to brown.

CHOCOLATE HONEY-PIE.

Beat yolks of two eggs and white of one, leaving out one white for meringue; add $\frac{1}{2}$ cup honey; one tablespoonful of grated chocolate; one tablespoonful of butter, $\frac{1}{2}$ cup of sweet milk; one teaspoonful of vanilla, warm; pour into pie-plates lined with good paste, and bake until the paste is brown. These recipes will make one pie each.

Horse Cave, Ky. Mrs. C. S. RHEA.

HONEY FILLING

Cream 2 tablespoonfuls of candied honey, and whip together with one cupful of thick cream. Flavor with lemon.

HONEY FROSTING.

Cook 4 tablespoonfuls of thin honey until a ball is formed when dropped into cold water. Pour into it the beaten white of an egg, and whip until cool. Flavor with cocoa or lemon.

SALAD DRESSING.

Beat together one tablespoonful candied honey; 2 tablespoonfuls thick sweet cream; one tablespoonful vinegar; $\frac{1}{4}$ teaspoonful mustard; pepper and salt to taste—no cooking. This is excellent over salad made from chopped apples and celery.

Wabeno, Wis. CECELIA W. GENTZ.

JEWISH HONEY-CAKES.

One cup each of sugar and honey; 4 eggs; 6 cakes chocolate, sweet, grated, or 18 tablespoonfuls ground chocolate; 3 cups flour; 2 teaspoonfuls baking-powder; one tablespoonful cinnamon; one teaspoonful cloves; very little allspice and vanilla. Cook in a thin layer, and cut in squares.

Ventura, Cal. FLORA MCINTYRE.

SANATORIUM GEMS.

Take 2 eggs, 2 cups sweet milk, $\frac{1}{4}$ teaspoonful salt, 2 cups entire-wheat flour. Beat very thoroughly; stand it on hot stove in gem-pans to brown the bottom for about five minutes; then bake in a good even oven for forty minutes.

Take 2 cups extracted honey, $\frac{1}{2}$ cup mashed red raspberries. Let it come to a boil, and eat on the hot buttered gems.

We enjoy our honey in many ways prepared as in recipe, and eaten on plain ice-cream. The children call it honey sundae.

Lockport, N. Y. Mrs. M. E. NEWMAN.

LADYFINGER DOUGHNUTS.

Beat 2 eggs light; sift into one cup of flour one heaping teaspoonful of baking-powder; three rounding teaspoonfuls of crisco; then melt one medium sized cup of extracted honey; one level teaspoonful of soda dissolved in 2 tablespoonfuls of sour milk. Flavor to suit taste. Add sufficient flour for as soft a dough as can be rolled, and cut in strip $\frac{1}{2}$ to $\frac{3}{4}$ inch, and 2 to 4 inches long. Fry in crisco. These fingers usually turn themselves when cooked on one side if cut the right size.

Boulogne, Fla. Mrs. H. E. KILBURY.

CANNED PICKLES.

Put small even-sized pickles in salt for 24 hours. Then pack in glass or stone jars as closely as possible. Slice thinly a small quantity of horseradish root, and put a little in each can; also a small pinch of dill and mustard seed in the top of the can. Put the jars in a pan of cold water, first putting a folded cloth beneath the jars to prevent breaking, and place all on the stove to heat. In a granite kettle put enough cider or honey vinegar to cover the pickles. Season the vinegar with red and black pepper. Use from 4 to 8 tablespoonfuls of extracted

honey to each quart of vinegar. Allow the honey, pepper, and vinegar to come to a boil; pour over the pickles. In ten minutes pour back into the kettle to boil again; fill the cans again with the vinegar, and seal hot. It is easy to pour the vinegar out without the pickles coming out if they have been closely packed. Any of the things except vinegar, honey, and pepper may be omitted if any are disliked or not obtainable.

NEW CINGEREAD.

One cup of extracted honey; a tablespoonful of melted butter; one tablespoonful of ginger; yolk of an egg beaten together, to which add a teaspoonful of soda dissolved in $\frac{1}{2}$ cup of buttermilk; then $1\frac{1}{2}$ cups of flour. Lastly, the white of an egg beaten stiff. Bake in a quick oven to a light brown.

Cora, Mo. Mrs. MARY TROYER.

Honey baked beans. Recipe by Rose A. Hambly.

HONEY BAKED BEANS.

Soak over night one pint of small white beans. Bring to a boil, adding baking-soda the size of a bean, and allow to simmer for half an hour. Drain, and cook till tender in salted water, but not long enough to break the skins. Drain and rinse the beans, and put them in an earthen bean-pot. Pour over them a pint of milk, adding a tablespoonful of butter, 2 tablespoonfuls honey, and a pinch of cayenne pepper. Cover closely, and bake in a slow oven till the milk is absorbed.

HONEY RICE PUDDING.

One cupful boiled rice (any cooked cereal may be used), one pint of milk; 2 eggs; a pinch of salt; one teaspoonful butter; half cupful honey. Bake, and serve hot or cold.

Rose Isle, Manitoba. ROSE A. HAMBLY.

CUSHSHAWS, OR POTATO PUMPKIN, COOKED WITH HONEY.

Wash the outside of the pumpkin clean; then cut it into pieces about three inches square, and place in a preserving-kettle of about one gallon capacity, with one teacupful of water and $1\frac{1}{2}$ or 2 teacupfuls of honey. Let it cook slowly till the water and honey become a thick syrup, and the pumpkin well done and candied.

This is delicious, hot or cold, and a dish which my family is very fond of.

Millett, Tex. Mrs. J. J. SOSSAMAN.

HONEY MINCE MEAT.

One bowl of meat chopped fine; and two bowls of apples. Add spice of all kinds to taste, and raisins and currants in abundance; vinegar, one cup, and sweeten with honey. Cook until tender. If you have more than you wish to use at once, can in glass jars. The longer you keep it the better it will be.

HONEY BREAD.

I take the water off from the potatoes at noon and put two or three potatoes through the ricer into the water. When it cools I put a yeast cake in the

water and let it set until toward night. I then stir it up pretty stiff and keep it warm. In the morning I add a tablespoonful of salt, two tablespoonfuls of lard and two or three tablespoonfuls of honey; then mix it stiff with flour and keep in a warm place. Mix down when light; and, when light again, make it into loaves; and, when light again, bake for an hour in a good oven. The honey keeps the bread moist, and improves the flavor.

Carpinteria, Cal.

MRS. A. L. DUPRAY.

SWEET-POTATO PUDDING.

One quart of grated sweet-potato; 2 well-beaten eggs; $\frac{3}{4}$ cupful of honey; $1\frac{1}{2}$ cupfuls of rich milk; 2 rounding tablespoonfuls of flour; nutmeg and cinnamon to suit the taste. Rub the potato through the food chopper using the medium knife. Mix well with the other ingredients and pour into a well-greased pan. Bake for about one hour in a moderate oven, stirring occasionally. Serve hot with hard sauce. It is also very good cold.

HONEY FOR BURNS.

Make a paste of honey and soda. Spread on the burn, cover with cotton and cloths. The pain is quickly relieved. Of course this is not for serious burns, but it is an excellent remedy for those painful little accidents which befall even the most careful person.

Concord, Tenn.

MISS DAISY F. RULE.

BROWN BREAD.

Take 2 cups buttermilk; $\frac{1}{2}$ cup each of dark honey, cornmeal, and white flour; 2 cups graham flour; 2 teaspoonfuls soda; one teaspoonful salt. Add raisins, currants, or dates. Bake 20 to 25 minutes.

San Jacinto, Cal.

A. K. WHIDDEN.

HONEY RICE PUDDING.

Bake 3 quarts of milk and one cup of rice in a slow oven for about 3 hours, stirring occasionally. When partly done add salt, one cup of raisins, and sweeten to taste with honey. Add more milk if pudding seems too thick. A delicious pudding.

HONEY HERMITS.

Two cups dark honey, $\frac{1}{2}$ cup molasses, $\frac{1}{2}$ cup water (warm), $1\frac{1}{2}$ level tablespoonfuls soda, 2 teaspoonfuls salt, 6 tablespoonfuls melted shortening, 1 cup seedless raisins. Flavor with vanilla. Stir very stiff with flour (about all you can stir into it). Drop by spoonfuls on well-greased tins, and bake in slow oven as they scorch easily.

HONEY CUCUMBER PICKLES.

Soak small cucumbers in weak brine over night. Boil a mixture of 2 cups vinegar, 1 cup water, 1 cup dark honey, 2 teaspoonfuls cinnamon, 1 teaspoonful allspice or cloves. Put pickles in jar and pour hot mixture over them and seal. Recipe for one quart. Pickles do not wilt.

Battle Creek, Mich. MRS. CHAS. A. JOHNSON.

HONEY COOKIES.

Melt $\frac{1}{2}$ cup of extracted honey; add 2 well-beaten eggs; $\frac{1}{2}$ cup of molasses or syrup; one cup of thick sour cream; a teaspoonful of soda; $\frac{1}{2}$ teaspoonful each of ginger and cinnamon; a pinch of salt, and flour to roll; cut out and bake in hot oven.

Osceola, Neb.

MRS. W. A. CARNINE.

TO PREVENT GRAPE JELLY CANDYING.

Add 2 tablespoonfuls extracted honey to 1 lb. of jelly. Let it boil two minutes longer, then fill your jelly glasses.

COOKIES.

One cup extracted honey; one cup light-brown sugar; 2 eggs well beaten; a level tablespoonful of soda dissolved in 3 tablespoonfuls of vinegar; pinch of salt; flour to stiffen (about 3 cupfuls in this altitude). Mix at night, and bake in the morning.

HONEY BROWN BREAD.

Take 2 eggs, beaten very light; one cup honey, white or dark; 3 cups sour milk; 2 large cups of white flour; 3 large cups graham flour; 3 teaspoonfuls soda, level, sifted in flour; one teaspoonful salt. Bake in a rather slow oven 45 minutes or more. This will make 2 loaves, and keeps moist and soft a long time.

Osceola, Wis.

L. W. CHATFIELD.

APPLE HONEY PUDDING.

Bread crumbs, $1\frac{1}{2}$ cups; 2 beaten eggs; 1-3 cup extracted honey; $\frac{1}{4}$ teaspoonful soda; 2 medium-sized apples chopped rather fine. Mix, and add $\frac{3}{4}$ cup of water. Bake until firm in the center, about 20 minutes. Keep covered until the last few minutes. Turn out on plate, and serve with whipped cream sweetened with a little slightly warmed honey. Enough for four persons. Good warm or cold.

Glenn, Cal.

MRS. S. C. DAVIS.

Pumpkin pie. Recipe by Mrs. C. A. Smith.

I have kept bees over thirty years, and have used honey more or less in my cooking, and can say that I fully appreciate its value. Where honey is used, the baked goods do not get dry and hard, and that last used is really better and more moist than when first baked. In any recipe that calls for New Orleans molasses, honey can be substituted, and is much better and more wholesome. I substitute honey molasses in mince pies, and find they are much nicer.

PUMPKIN PIES.

Sifted pumpkin, 2 cups; sugar and honey, one cup each; flour, 4 tablespoonfuls; ginger, 2 teaspoonfuls; cinnamon, one teaspoonful. Add milk with all its cream—enough for two pies. Jersey milk is best.

[When making this pie, we modified the recipe as follows: we used only 2-3 cup sugar and made the addition of two eggs (four would be better, perhaps). We found that 4 cups of milk were required.—Ed.]

GINGER CAKE.

Honey, 2-3 cup; sugar, $\frac{1}{2}$ cup; one egg; butter-milk, one cup; flour, 4 tablespoonfuls; ginger, 2 teaspoonfuls; cinnamon, one teaspoonful. Add milk with all its cream—enough for two pies. Jersey milk is best.

CREAM COOKIES.

Sugar, one cup; honey, $\frac{1}{2}$ cup; one egg; sour cream, one cup; melted butter, 1-3 cup; soda, one teaspoonful; baking-powder, one teaspoonful; flavor with nutmeg or vanilla; flour enough to roll nicely, but not too hard a dough, for that spoils them.

GINGER COOKIES.

Sugar, one cup; honey, 2-3 cup; one egg; sour cream, one cup; melted butter, $\frac{1}{2}$ cup; one teaspoonful each of soda and baking-powder; 2 teaspoonfuls of ginger; one of cinnamon; flour enough to roll.

Everett, O.

MRS. C. A. SMITH.

PLUM PUDDING.

Sifted flour, 3 cups; eggs, 3; sugar, 2 3/4 cup; honey, 1/2 cup; milk, 1/2 pint; finely chopped suet, one large cup; English currants and raisins, each one cup; mace, cloves, and cinnamon, 1/2 teaspoonful each, or to taste; baking-powder, 3 teaspoonfuls. Steam 3 hours.

PUDDING SAUCE.

Sugar, 2 cups, dissolved in boiling water; 1/2 pint cornstarch, 2 tablespoonfuls worked smooth in cold water, one cup, and stirred into the boiling sugar with nice butter the size of an egg. Boil until clear. Remove from the stove and add half a cup of honey. Flavor with vanilla.

Everett, O.

MRS. C. A. SMITH.

Fruit cookies are made the same as the above by adding one cup of shortening, one cup of chopped raisins; 1/4 teaspoonful of cinnamon and allspice; 1/2 teaspoonful cloves and nutmeg; cream sugar and shortening, and proceed as above.

Colo, Iowa.

MRS. OSCAR TRIPP.

INDIAN MEAL PUDDING.

Scald 2 quarts of sweet skim milk; add 2 cups of corn meal. Remove it from the stove, and add 1/2 pound honey; 1/2 cup raisins; one egg; butter the size of an egg; 2 teaspoonfuls of cinnamon; one teaspoonful of salt. Bake two hours. Stir it up every half-hour until done.

S. Shaftsbury, Vt. MRS. GEO. E. MATTISON.

HONEY YEAST.

One pint plain potato water; one tablespoonful honey; 2 tablespoonfuls yeast. Set in a warm place, and in a few minutes it will be up and ready to mix with or to be set away, and it will keep many days in a cool place.

In fact, the yeast-plant will act much more readily in yeast sweetened with honey, and keeps a much longer time than when sweetened with any kind of sugar.

Kanab, Utah.

MRS. ISRAEL HEATON.

HONEY COOKIES.

Blend 1/2 cup honey, one teaspoonful butter; one egg beaten light; 1/2 teaspoonful baking-powder; pinch of salt; flour to make a stiff drop in buttered tins. Bake in a slow oven.

CHOCOLATE HONEY TAFFY.

One cup strained honey; 1-3 cup sugar; one piece of chocolate an inch square. Boil until it makes a soft ball in cold water. Add one teaspoonful vanilla. Put into a buttered dish to cool. Pull until light.

PLAIN HONEY TAFFY.

Two cups honey; 1/2 cup sugar. Boil until it makes a soft ball in cold water. Add one teaspoonful vanilla. Put in a buttered dish to cool, and pull until light. If the pan that the honey taffy is cooked in is buttered around the top the honey will not boil over on the stove.

HONEY JELLY.

To one cup fruit-juice add one cup honey. Boil from 15 to 20 minutes. [We find that one must be careful in the boiling, otherwise the jelly will have a slight burnt honey taste.]

Wheatland, Wyo.

BARBARA E. HARTER.

WEDDING CAKE.

One cup each of extracted honey, butter, New Orleans molasses; 3 eggs well beaten; 1/2 cup strong coffee; one cup buttermilk; 2 teaspoonfuls soda dissolved in 1-3 cup boiling water; one grated nutmeg; 2 teaspoonfuls cinnamon; one teaspoonful cloves; one cup strawberry preserves; two pounds raisins, seeded; 2 lbs. currants; 1/2 lb. citron; 1/2 lb. candied lemon peel; 1/2 lb. candied orange peel; 6 cups flour. Mix in order given. Bake one hour.

Mankato, Minn.

MRS. W. W. RUSSEL.

HONEY SANDWICH CAKE.

Take 1 1/2 cups flour; one cup honey; 2 eggs, 2 oz. butter; 1 1/2 teaspoonfuls baking powder; one teaspoonful of cinnamon, cream, butter, and honey; sift in half the flour; add the eggs, beaten up; also the remaining flour and cinnamon. When ready for the oven, add the baking-powder. Bake in two layers; and, when cold, spread granulated honey between them. Bake each layer 25 minutes in a moderate oven.

MRS. A. S. ASHTON.

Beauharnois, Quebec, Canada.

HONEY HERMITS.

Take 1-3 cupful of butter, 1 1-3 cupfuls extracted honey, 1/2 cupful milk, 2 eggs, 2 level teaspoonfuls baking-powder, 1/2 level teaspoonful salt, one cupful raisins, chopped; 1/2 teaspoonful nutmeg and cinnamon; about 2 1/4 cupfuls of flour. Melt the butter; add the honey and beaten eggs; mix, add salt, spice, milk, baking-powder, flour (gradually), and beat well. Stir in raisins, floured. Drop from a teaspoon in small rounds on a buttered tin. Bake in a quick oven until brown.

HONEY CUSTARD.

Take 4 eggs, well beaten; one cupful extracted honey; 4 cupfuls sweet milk. Mix thoroughly; sprinkle nutmeg on top, and bake 30 minutes. Number served, 9 persons.

Chippewa Falls, Wis.

MRS. JOHN SHAFER.

Ginger drop cakes. Recipe by M. I. Jeffrey.

GINGER DROP CAKES.

One cup each of dark honey, sugar, and lard; 3/4 cup sweet milk; one egg; one tablespoonful ginger; 1/2 teaspoonful salt; one teaspoonful (rounded) soda in a little hot water. Flour to make the batter stiff enough to drop from spoon.

Bethesda, O.

M. I. JEFFREY.

FRUIT SALAD DRESSING.

Yolks of two eggs; 1/2 cup honey; 2 tablespoonfuls flour; one tablespoonful sugar; 1/2 cup cream whipped. Mix flour and sugar; stir in honey and juice of two lemons.

Fleming, Ohio.

MRS. WM. JONES.

HONEY CANDY.

Take 2 cups extracted honey; one cup white sugar; 3 tablespoonfuls water; stir all together. Boil until it will harden when dropped in cold water. Turn out into buttered tin to cool partly. Then pull like molasses candy.

HONEY COOKIES.

One egg, one cup sour cream; 1/2 cup sugar; one cup extracted honey; 3 tablespoonfuls butter; one teaspoonful cream tartar; one teaspoonful soda. Add flour enough to roll out and handle nicely to make them soft. Bake in a moderate oven.

SUBSCRIBER.

HONEY APPLE MARMALADE.

Cook tart apples until smooth; add 1 lb. of honey to 2 lbs. of fruit. Cook until about like cake batter. Then put into crocks or jars without sealing. It will cut out in a few weeks.

POPCORN BALLS.

Pop a few ears of popcorn, and have ready in large dish. Boil a quart of honey until it will crack. Let it partly cool; then pour over a dish of popcorn, and make into balls.

Laurel Springs, N. C.

MRS. J. T. REEVES.

GINGERBREAD.

Take 3 eggs; one cup sugar; one cup butter; one cup honey, one cup sour milk; 3 cups flour; 2 heaping teaspoonfuls of ginger; 2 teaspoonfuls of cinnamon; one teaspoonful of cloves if you like; one teaspoonful of soda.

Sayers, Tex.

MRS. ANNIE WOODWARD.

HONEY-DROP COOKIES.

Beat together 2 eggs and one cup of honey, $\frac{1}{2}$ cup of butter, $1\frac{1}{2}$ cups of flour, one teaspoonful baking-powder; $1\frac{1}{2}$ teaspoonfuls caraway seeds. Drop with a spoon in a butter-tin. Bake till brown.

HONEY WAFFLES.

Cream together one egg well beaten, 2-3 cup of butter, one cup of honey, $1\frac{1}{2}$ teaspoonfuls of baking-powder, one tablespoonful vanilla; flour to make quite stiff. Roll thin. Bake brown.

North Ferrisburg, Vt.

MRS. A. C. PALMER.

HONEY ICE CREAM.

One quart of fresh cream; one cup honey. Mix well, and freeze. No flavoring is required—delicious.

State River, Ont., Can.

JAMES M. MUNRO.

TOMATO PRESERVES.

Take 3 lbs. honey, 6 of tomatoes, and cook.

Stanton, N. D.

MRS. M. M. OLDS.

HONEY VINEGAR.

I find that honey makes excellent vinegar. I usually use the water I dip my capping-knife in, which makes it sweet enough. If the water is boiled, there is no difficulty in making vinegar in a short time if you have a good vinegar body, sometimes known as "mother," to start it.

HONEY YEAST.

Save a start of fresh potato yeast; stir it thick with honey. I usually save part of a teacupful of the old-fashioned potato yeast, and stir in honey enough to make a syrup. This will keep sweet for days in warm weather, and comes in very handy in warm weather when yeast cakes cannot be obtained.

PLUM AND CHERRY PRESERVES.

I find, also, in using sour plums for preserves it is better than sugar, using 1 lb. of plums to one of honey. Let the honey come to a boil, then put the fruit in and boil hard. Skim when needed, till done.

Wild-ground-cherry preserves are nice made the same way. Many people prefer the honey flavor to that of sugar.

HONEY MINCEMEAT.

Honey used in mincemeat is preferable to sugar, and I like it better than molasses with any recipe I ever used. Take one gallon of fresh meat, chopped fine; one gallon apples peeled, cored, and chopped fine; 1 lb. raisins; 1 lb. of currants; cinnamon to taste; black pepper to taste; a few cloves and allspice; one quart of vinegar, if good and sour (more if not); honey enough to make it as sweet as desired. I make any amount of this late in the fall, and fill what empty fruit-jars I have; and it is always ready for use as long as it lasts. The jars do not need to be sealed.

CHOW-CHOW.

One gallon salt cucumbers; $\frac{1}{2}$ gallon green tomatoes; $\frac{1}{2}$ gallon cabbage; $\frac{1}{4}$ gallon strong winter onions (measured after chopping). I usually run all separate through a food-chopper, using the coarsest knife, then mix them and let them stand over night. In the morning, place them in a colander and let drain until all the juice has run off. Place in a kettle (granite ware preferred); cover with vinegar. Let it come to a boil; add tumeric, mustard, black pepper, cinnamon, allspice, cloves to taste. Add a pint of honey, and boil an hour. Place it in a jar or small keg, with a cloth, board, and weight, to keep the vegetables under the vinegar. Do not cover with a weight till the chow is cool. Made in this way in the fall it will keep till warm weather. Then seal and place in fruit-jars and seal for summer use.

If fresh cucumbers were used, sprinkle a handful of salt over the vegetables and let it stand.

HONEY COOKIES.

Take 3 eggs, well beaten; $\frac{1}{2}$ lb. of butter or other shortening; one pint of honey; lemon, or nutmeg to flavor; one small cup of milk; stir all together. Two teaspoonfuls of baking-powder; flour or graham enough to make a nice dough. Roll thin and cut with a biscuit-cutter. Place in a buttered dripper, and cook in a hot oven. In using graham use $\frac{1}{2}$ flour.

Hankville, Utah.

MRS. J. H. NOYES.

EAST INDIAN PUDDING.

This is one of the most delicious desserts in which honey is used. To make it, soak three cupfuls of fine bread crumbs in two cupfuls of cold water for five minutes. Drain off the water and press the crumbs until they are almost dry; then mix thoroughly with one tablespoonful of butter, one-quarter of a teaspoonful of salt, five egg yolks, four tablespoonfuls of honey, one-half teaspoonful of powdered cinnamon and one-half cupful of raisins. When the ingredients have been well mixed add the beaten whites of the eggs flavored with one-half teaspoonful of grated lemon peel. Bake in an earthenware dish for twenty-five minutes.—Courtesy *Mother's Magazine*.

HONEY CORNBREAD.

Thoroughly mix two pounds of cornmeal and one-quarter pound of flour and add four cupfuls of boiling water. Stir briskly for three minutes; set aside and to two well-beaten eggs add two teaspoonfuls of honey, two teaspoonfuls of salt, one tablespoonful of melted butter, one and one-half cupfuls of lukewarm yeast mixture. When thoroughly mixed stir into the flour and meal and continue the stirring for half an hour. Pour into a well-greased, deep baking pan, cover with a piece of paper and set in a warm place for two hours to rise. Then remove the paper and bake in a moderate oven until the top is a golden brown. This bread should be served hot, but any that is left over can be made as good as when fresh by reheating in the oven.—Courtesy *Mother's Magazine*.

HONEY RICE PUDDING.

Wash and carefully clean one-half cupful of rice. Put in a deep baking-dish and stir in one and one-half cupfuls of milk, four tablespoonfuls of honey, one-half teaspoonful of salt and one tablespoonful of finely chopped lemon peel. Bake in a moderate oven for two hours. Stir frequently during the first hour and a half of baking. Serve cold with milk or cream.—Courtesy *Mother's Magazine*.

BREAD PUDDING.

Toast very slightly six slices of stale bread. Cut each slice into six small squares. Butter the squares and with them cover the bottom of a well-greased baking dish. Sprinkle in a few raisins and dust lightly with cinnamon. Put in another layer of

bread and more raisins and cinnamon and continue until all of the bread is used up. Make a custard of one cupful of milk, three tablespoonfuls of honey, and a pinch of salt. Bring to the boiling-point in a double boiler and stir in two well-beaten eggs. Remove from fire and continue stirring until cool. Pour the custard over the bread and bake in a moderate oven for half an hour.—*Courtesy Mother's Magazine.*

HONKY TAPIOCA.

Into a double boiler put two tablespoonfuls of fine tapioca and one cupful of milk. Cook until the tapioca is transparent, stirring constantly. Then add the yolks of two eggs, well beaten and sweetened with two tablespoonfuls of honey, and seasoned with one-quarter of a teaspoonful of salt. Stir the mixture until it has thickened; then add the beaten whites of the eggs and continue the stirring for three minutes longer. Remove from the fire and when cool stir in one teaspoonful of vanilla extract. Serve cold.—*Courtesy Mother's Magazine.*

EGGLESS CAKE.

One cup honey, $\frac{1}{2}$ cup sugar; $\frac{1}{2}$ cup butter; one teaspoonful saleratus; one teaspoonful ginger; flour. Dissolve the saleratus in a little water, and add flour enough to thicken.

Willowemoc, N. Y. MRS. MARVIN S. STEWART.

PLUM BUTTER.

Two quarts of plums; 8 cups of extracted honey; or two of honey and one of sugar, if you like. Very good.

Columbus, Ohio. MRS. B. F. FRAVEL.

HONEY-CURED MEAT.

In attempting to apply a dry "sugar cure" to meat we always experienced this difficulty: When meat has lain long enough for all the animal heat to get out, the surface has a firm dry glaze of tissue to which it is very difficult to get any dry mixture to stick. Even where the salt is "piled on" it often fails to "connect" with the meat under the glaze. Somewhere I got the suggestion to use New Orleans molasses instead of sugar, and we tried it one year with good results; but the next butchering time found me with no molasses on hand, but plenty of honey; and as I had "read in the books" of the preservative effect of honey I decided to "try it on the hog." Since that time we have never changed our "process," and never had a single piece of meat that was not A1. I have had it "sampled" at farmers' institutes, and by visitors at my home, and the verdict always is: "Fine—best I ever tasted," etc. Here is the whole process:

Let meat get thoroughly cooled out, but not frozen. Trim shoulders so there will be no "flap" to hang against the leg piece. Take one piece at a time in a dishpan, and apply a coating of honey. This may be done either with the hand or a swab; but care should be taken to rub it into every part of the surface, skin as well as flesh side, and also well in around the bone at the hock end (we generally saw off about four inches of the shank and use it while it's fresh). The pieces are then handed to another, who applies as much of the following mixture as will stick to the honey: 5 lbs. salt; 2 oz. black pepper; 1 oz. cayenne pepper. Saltpeper may be added if liked, but we do not like it nor consider it wholesome.

Generally with us at the end of about three weeks it may then be hung and smoked, and that is all there is to it; but with very large meat, or if some pieces show "fresh-looking" places, it gets a second application. This is seldom necessary or desirable in this climate, as the meat is apt to get too much salt to taste good; but in a more humid climate it would probably be well to give a second application to all but one or two pieces. If they keep "just as well" you will know it is not necessary for you.

Last spring we put down a barrel of "corned beef," the pickle for which was made with salt, honey, and pepper as above, and we know that it is the finest kind of eating. Strips of dried beef were also dipped in this pickle while boiling for about ten minutes, and then hung up to dry.

North Platte, Neb.

LOUIS MACEY.

GINGERBREAD.

One cup of honey and one of shortening; $\frac{1}{2}$ cup sour milk; one teaspoonful soda; one teaspoonful of ginger, and enough flour to roll out nicely. When done, take the white of one egg and make a frosting.

Fayette, Ia.

H. B. MORRISON.

MRS. A. H. S., Vienna, Va.—We use honey to make Amana Colony honey cookies, as follows: Let one pint of honey (extracted) come to a boil; let cool a little, then add 2 well-beaten eggs, $\frac{1}{2}$ pound of sugar, $\frac{1}{2}$ pound of almonds or other nuts, 10 cents' worth of citron chopped fine, 1 teaspoonful of cinnamon, $\frac{1}{2}$ teaspoonful of cloves, $1\frac{1}{2}$ even tablespoonfuls saleratus; stir thoroughly and add enough flour to make a stiff dough. Cut in fancy shapes and bake in a moderate oven; frost if desired. If the above recipe be carefully followed, I am sure it will be found satisfactory.—*Courtesy Practical Farmer*

HONEY BREAKFAST TOAST.

Beat 1 egg until light, add a pinch of salt, 2 tablespoonfuls of honey and 1 cupful of milk. Into this dip half slices of stale bread; brown quickly on both sides in hot butter or oil; serve with butter or honey.—*Courtesy Practical Farmer.*

GINGERBREAD NUTS.

Put 1 pound of brown sugar, 1 pound honey and grated rind of half a lemon in a saucepan over the fire and let it simmer well together. Remove from fire, add $\frac{1}{4}$ pound of butter, 1 ounce of ginger, 1 teaspoonful of soda, and 2 pounds of flour; roll thin, cut, and bake about 20 minutes in a slow oven.—*Courtesy Practical Farmer.*

HONEY CARAWAY LOAF CAKE.

Cream $\frac{1}{2}$ cupful of butter, add $\frac{1}{2}$ cupful each of sugar and honey, 2 well-beaten eggs, 2 cupfuls of flour sifted with 1 level teaspoonful of baking-powder and 1 teaspoonful of caraway seeds. Pour into a buttered shallow loaf-pan and bake about 25 minutes.—*Courtesy Practical Farmer.*

HONEY ANGEL CAKE.

Sift $1\frac{1}{2}$ cupfuls of flour four times, add 1 teaspoonful of cream of tartar, and sift again. Beat the whites of 11 eggs until stiff, add $1\frac{1}{2}$ cupfuls of white honey, beat lightly, then add the flour. Do not stop beating until you put in the pan. Bake in a moderate oven.—*Courtesy Practical Farmer.*

SPICED HONEY CAKES.

Two coffee-cups of flour, two tablespoonfuls of butter; one teaspoonful of ginger; $\frac{1}{2}$ teaspoonful of cinnamon; one cup of honey. Salt; stir all together, add last thing one cup of boiling water poured on one heaping teaspoonful of soda.

Chenango Forks, N. Y. MRS. E. W. LANTZ.

[The cake that we made with this recipe seemed, for some reason, to be rather heavy. We would suggest that $2\frac{3}{4}$ cups of flour be used or else less hot water, and that one egg be included, beaten separately.—ED.]

HONEY GEMS.

Two quarts flour, three tablespoonfuls melted lard, three-quarters pint honey, one-half pint molasses, four heaping tablespoonfuls brown sugar, one and a half level tablespoonfuls soda, one level teaspoonful

salt, one-third pint water, one-half teaspoonful extract vanilla.—From Bulletin 184, Ontario Department of Agriculture.

CORN BREAD.

Take 2 cups corn meal; one egg; one cup sour milk; $\frac{1}{2}$ teaspoonful soda; one teaspoonful baking-powder; $\frac{1}{2}$ spoonful salt; 2 tablespoonfuls honey. Mix with water for desired consistency.

Greensburg, La. E. C. DAVIS.

HONEY WITH FRESH FRUITS.

There is a wide field for the use of honey in connection with fresh fruits. Fruits which are naturally rather tart and lacking in rich flavor are greatly improved and become very palatable when eaten at table with honey—possibly excepting buckwheat honey.

Fresh currants make a fine relish eaten with various roast meats. Honey should be poured lightly over the fruit in individual dishes, then mash the fruit with a fork; a little water may be added if desired. Sour cherries, pitted, may be used in the same fashion; also cut-up peaches—this is especially good when the peaches are rather tart; well-ripened gooseberries ditto. Strawberries, red raspberries, and blackberries come into the list too.

Of course, where good thick cream is available it is to be preferred; but in cities and towns, or where real cream is scarcely known, honey makes an excellent substitute or variation.

New Jersey. B. KEEP.

HONEY VINEGAR

Honey vinegar can be made by using one and one-half ounces of honey to one gallon of clear soft water. Store in a barrel or other vessel. It should be kept in a warm place, with an opening in the vessel to allow the air to circulate freely, thus causing it to come to perfection more quickly. At the end of the year it will be ready for use. Its keeping qualities are excellent, and the best of pickles can be made with it. There is, perhaps, nothing superior for using with vegetable and meat salads.—From Bulletin 184, Ontario Department of Agriculture.

HONEY PUFFCAKES.

Cream 3 tablespoonfuls of butter with $\frac{1}{2}$ cupful of sugar, add $\frac{1}{2}$ cupful of honey, 1 cupful of milk. 2 well-beaten eggs, a pinch of salt, 2 teaspoonfuls baking-powder sifted several times with 5 cupfuls of flour; flavor with cinnamon, nutmeg, or lemon, and drop by teaspoonfuls into very hot lard or oil. Brown well. These have been very popular for years and are well worth trying.

For the benefit of young cooks I would say that in frying these cakes or doughnuts, it is important to have the lard sufficiently hot before beginning. A good way to try it is by dropping in a crumb of bread. If this browns while you count sixty it is right. If only a few cakes are put in at a time, adding others at intervals of a few minutes, the temperature will be kept more even than if the pan is filled at once.—Courtesy *Practical Farmer*.

For cough or irritated throat, take 2 tablespoonfuls each of honey and glycerine, 1 tablespoonful of lemon juice, with a dash of ginger. Keep the mixture warm and use a little as needed.

A teaspoonful of heated honey will often quickly stop a cough and seems especially effective at night.—*Practical Farmer*.

HONEY FOR ASTHMA.

My husband was a sufferer from asthma, and was getting worse every year. We secured some bees, and he has used lots of honey since then. The first winter passed with hardly a trace of the asthma. We did not connect the cure with the honey until the spring of 1912, which was a failure in the early part, and we got along without honey. The asthma

commenced again until we went to using honey. Once since, in 1914, we bought some new molasses and he left off the honey for awhile, and then the asthma returned again.

If it was the honey that caused the cure it has been worth lots to us, as we were thinking seriously of going to another climate to see if it would benefit the asthma. To be sure, he will continue the remedy, as it is a very agreeable one; and if we should get out of honey the bees are liable to be "robbed." Laurel Springs, N. C. MRS. J. T. REEVES.

COUGH SYRUP.

Boil one quart of ripe wild cherries in one quart of water for one hour; then strain, and boil to one pint. Add $\frac{1}{2}$ pint of honey, and juice of 2 lemons; one teaspoonful of liquid tar; then let it come to a boil. Then bottle; $\frac{1}{2}$ teaspoonful for a dose.

Hartville, O. MRS. J. A. KREIGHBAUM.

HONEY FOR BOILS.

Take a teaspoonful of honey and make a paste with wheat flour so it will adhere to a cloth. Put it on the boil like a poultice.

BEST COUGH REMEDY.

Get 1 oz. tincture of lobelia; $\frac{1}{4}$ oz. capsicum; 15 drops oil of wintergreen; $\frac{1}{2}$ pint pure honey. Put all into a pint can or bottle, and shake thoroughly. Dose: one teaspoonful three times a day, shaking well before using.

Huntington, Ind. MRS. E. H. UPSON.

A COUGH REMEDY.

Take one ten-cent package each of the following in the crude state. Comfrey root, elecampane, boxwood, and hoarhound made into a decoction boiled. Add one quart of honey and boil into a syrup.

Bunceton, Mo. J. R. MARYE.

RECIPE FOR CHRONIC COUGH.

One pint each of lemon juice, olive oil, and extracted honey; $\frac{1}{2}$ pint Jamaica rum (this may be left out); one fresh egg. Put the lemon juice into a fruit-jar or large-mouthed bottle; wash the egg, and drop it *unbroken* into the lemon juice. In about 24 hours the shell of the egg will be dissolved. Then remove the tough inside skin, being careful to leave every particle of the shell in the lemon juice. Beat all together; warm it enough to mix well, and bottle. Keep in a cool place. Dose, a teaspoonful frequently.

Phoenix, Ariz. JENNIE C. GIBSON.

COUGH MEDICINE.

Three tablespoonfuls each of honey, lemon juice, and sugar (granulated); one tablespoonful of glycerine. Take occasionally during the day by the teaspoonful. One just before retiring will ease the throat wonderfully. With us this has proven invaluable with many hard colds, accompanied by severe coughing, and also for hoarseness.

Salisbury, Vt. F. J. PERKSON.

COUGH MEDICINE.

Take 5 cents' worth each of boneset, sage, and horehound. Boil in 2 quarts of water. Strain through a cloth, and add one cup of honey, one cup of syrup (either maple or cane). Boil all together until it forms a thin syrup. Then add the juice of two lemons and one tablespoonful of castor oil. Take a spoonful as often as you feel like coughing.

Butler, Ind. MRS. D. H. KNISELY.

REMEDY FOR SORE THROAT.

Sweeten strong sage tea with lots of honey, and in it drop a little carbolic acid. Use often as a wash or gargle. No harm if children swallow a little. In bad cases, first clean mouth and throat with a wash made from baking-soda. All washes should be warm. C. L. W.

Heads of Grain from Different Fields

The Backlot Buzzer

A city man wrote in the other day, and wanted to know what to do about his bees; then were working on the gold road, and he was afraid they'd get the hay fever.

Swarming with Queen-cells; Was it the Season or Something Else?

I have been thinking for several days past of writing you or Dr. Miller in regard to the abnormal condition of bees in this locality (and I guess it's quite general from what I am able to learn from other localities). Yesterday, while talking with a neighbor in regard to the condition (and he did not seem to realize how much out of line they were), he urged me to write you, asking if you had ever had any experience like it, and what of the result and what to do.

We are all having swarming, some the last few weeks, and I haven't found any of them who have looked into the cause of it; but most of them have put the bees in new hives. I had a very strong colony swarm ten days ago. As the queen was clipped they were settling as I came to the yard. On looking through them very carefully I found no signs of a queen cell—not even an embryo cell; but what I did find was stacks of young bees and ten frames of brood, some sealed from top to bottom, end to end, and plenty of eggs and larvae of all ages, but not one sealed cell of honey in the brood-chamber, nor any honey, so far as I could see. They may have had a little honey in the supers (there were two on the hive as they needed them for room), but I could not detect any there. I gave them two frames of sealed honey on which the bees died last winter. The next day I looked through

ten other colonies, finding practically the same condition. I gave five of them two frames each of sealed stores. Of course this is not advisable generally, on account of danger of starting robbing. I contracted the entrances for 48 hours, and there was no robbing; but there was some excitement in the yard.

Have you any records of such abnormal conditions at this time of year with very little honey coming in?

What is the remedy, and what is likely to be the results?

Urbana, O., Aug. 30.

O. J. JONES.

This was referred to Dr. C. C. Miller, who replies:

The bees seem to be always trying some new stunt to emphasize the fact that we don't know very much about them. I'm not sure that I ever experienced exactly the same thing you have had, but at least some of the things you have had. You describe the hives as unusually full of brood, and not a cell of sealed honey in the brood-chamber. This year my hives were crammed with brood and no sealed honey in the brood-chamber, only in my case there was honey in the supers, and this was kept up through the clover flow. I never saw just the same thing before, and don't know for certain how to account for there being no honey sealed in the brood-combs. Indeed, there was very little honey unsealed in the brood-chamber—no room for it. I guess that the unusual wet and cold had something to do with it. The colonies were very strong, and brood-rearing went right on in days when bees could not get out, leaving only enough cells for the unsealed honey, for you know that, no matter how much sealed honey may be present, some is always kept unsealed for immediate use.

It used to be counted the right thing for bees to send out a swarm as soon as the first queen-cell is sealed, and when left to themselves they generally follow that rule. But unusual conditions or the meddling of the beekeeper may cause them to disregard it. Persistent cutting-out of queen-cells may result in swarming with only eggs in queen-cells, if, indeed, there be that much preparation. The excitement of other bees swarming will sometimes make a colony swarm before its normal time. Why might not the excitement of a sudden flow of honey do the same thing? This year my bees had probably the same experience as yours. After having done a good bit at storing on clover, they did almost nothing all through August. Then in the first part of September came a flow when the bees worked with an excitement I never saw excelled, and seldom equaled. I don't know whether any of mine swarmed, but I know there were swarms in the neighborhood, and it is just possible that bees swarmed here with as little preparation as yours.

Marengo, Ill.

C. C. MILLER.

Does a Laying Queen ever Desert Her Hive and Go into Another?

Does a laying queen ever leave her hive, go to another hive, and be accepted? An incident happened in my apiary which I cannot account for otherwise. I removed the queen from a fairly strong colony which had been fed to get in shape for building cells. By its side was a three-frame nucleus with a young laying queen. No nectar had been coming in, and the nucleus was very short of honey. In eight days, when looking in the supposed queenless colony for cells, I was surprised to find a laying queen with brood in all stages, and

still more surprised when looking in the nucleus to find no queen or eggs, but capped queen-cells.

I am as sure as one can be that the strong colony was not superseding, and the queen they have is marked like the one formerly in the nucleus. Did the queen get discouraged with such small proceedings in the nucleus? or did some of the workers in the strong colony come over and offer her a better job?

If one confines the queen to an upper story, placing a comb super between it and the lower story in order to have cells built below, then when cells are removed can the super and excluder be removed without danger of the old queen being killed?

Odon, Ind.

W. H. BAIR.

[Cases of this kind have been reported, but they are rare. It is not uncommon to find the bees gradually deserting a queenless hive, and going into another near by where there is a queen; but it is very seldom indeed where we find a *laying queen* swapping homes. The incident here reported may be accounted for in two ways: First, the nucleus may have swarmed out, as nuclei often do when short of stores; returned, and, instead of going back to the old hive, went into a stronger colony. Second, the bees in the nucleus may have attempted to ball the queen. Sometimes a queen under those conditions will run if she can elude her captors, and escape at the entrance, fly about for a time, and then return to her old hive near by.

A *virgin* queen will very often by mistake go into the wrong hive.

As to your last paragraph, we see no reason why you could not remove the excluder without danger to the queen. The colony odor in the lower and upper part of the hive would be the same; and unless there were virgins above, the old queen would be accepted below.—ED.]

Some Questions on Moving Bees

1. In preparing full colonies for a 300-mile shipment should there be a notched stick placed on the bottom-board to keep the bottom-bars from swinging sidewise?

2. Would anything be gained if the queen were caged ten days previous to shipment, and then liberated after shipment?

3. How much honey should be left in an eight-frame hive?

4. How much air space should be given above the frames?

5. Would an empty comb-honey super be all right?

6. Should I take water in the car and sprinkle the bees whenever they get uneasy?

Clarkston, Mich.

W. L. LOVEJOY.

[1. If you have loose-hanging frames such an arrangement is not only desirable but necessary. With self-spaced frames, either closed end or of the Hoffman type, it would not be needed.

2. We hardly think this would pay you, for under ordinary circumstances your sealed brood would not suffer on the journey, and in some cases the unsealed brood is all right also. Caging the queen would simply put the colony back, and you would have your labor of finding queens, caging them, releasing them, etc., besides.

3. It depends on the size of the colony and on the age of the combs. There is not as much danger, of course, of comb breakage if the combs are old and tough, and in that event the danger in having them too heavy with honey would not be as great. However, the rule is to send no more honey than the bees will require on the journey, in order to reduce weight and to reduce to the smallest possible amount the danger of breakage.

4. We advise tacking on a framework the size of the hive made of one-inch material, which is covered

with a heavy screen. This should go above and below. The two screens provide two inches additional space, and under ordinary circumstances this is enough.

5. There would be no great objections to the empty super except that it would take more room in the car, and we do not know that it would be any better than the one-inch space afforded by the screens mentioned above.

6. Yes, in hot weather you will need a good deal of water.—ED.]

More about Pollen in Sections

In editorial comment, page 82, Jan. 15, I note what is said about Mr. Sprout's trouble with pollen in sections. He has used queen-excluders, but they are not pollen-excluders. The editor refers to a comb or combs at the side of the brood-chamber as a means of holding it down. It occurs in colonies that do not swarm as well as in those that do, as these colonies are normal and have certainly all the combs in the brood-chamber. The pollen still goes up. He also speaks of empty cells. Tell us how to keep them empty. I suppose he advises going over the yard every other day and giving empty combs. This would be fun.

He also speaks of bees being creatures of habit, and says they must not be allowed to get the habit of placing pollen in sections. Do you suppose that the bees that place pollen in the sections this year will be there to place some there next year? Your contention might be all right for just one season, but this is an every-year occurrence.

Akron, N. Y., Feb. 15. WM. F. VOLLMER.

[We give it up. Who has had practical experience in preventing this very annoying trouble?—ED.]

The Cover Question

I have seen and used many kinds of covers for hives, but have always found that many, if not all, had their weak points. Some absorb water, and leak; others need painting too often, which is an expense as well as a labor; others rot out too quick, and still others get so hot on a real hot day that the frames of honey will melt down.

The new cover which I am using now has none of the above weak points. It never needs painting; will wear as long as the hives themselves; will not leak, and is the coolest cover I have ever found. What is it? It is aluminum. Some will say that it is too expensive; but if you will get it as thin as taggers' tin you will find that it is not expensive.

Simply order the aluminum in sheets a little larger than your old cover, and turn down the edges and nail them down, overlapping at each side and end to shed the water. Put this aluminum cover on a hive out in the sun with some other kind of hive-cover in reach; and after letting the same stand in the sun for an hour, place one hand on the aluminum cover and the other on your old cover, and you will find that, while the aluminum cover is hardly warm, the other cover will almost burn your hand. We all know that aluminum will not rust. Remember, do not paint this cover, and get it as thin as taggers' tin. Try this, friends, and be convinced and do away with paint and rotten covers.

Morgan, Ky.

J. E. JORDAN.

Aster Stores for Wintering

My bees are wintered on a combination consisting mostly of aster honey and sugar syrup. I find them to be good winter food. I do not have goldenrod. This year I will remove the supers before the aster flow in order to compel the bees to store their honey in the brood-chamber.

Lititz, Pa.

ELMER S. SNAVELY.

OUR HOMES

Editor

The harvest is plenteous, but the laborers are few.
—MATT. 9:37.

Behold the Lamb of God that taketh away the sin of the world.—JOHN 1:29.

He which converteth the sinner from the error of his way shall save a soul from death, and shall hide a multitude of sins.—JAMES 5:20.

"THE REMAKING AND MENDING OF MEN."

At our Medina Chautauqua this summer, Chaplain Kiplinger, of the Indiana State Prison, gave about the best talk in favor of prohibition that I ever heard. He had a large and appreciative audience, for which I thanked God; but it seems to me that the facts and figures he gave should be held up before the people, not only for the state of Ohio but throughout the United States and the whole wide world.

Perhaps I was specially prepared or fitted to take in the significance of that talk. I have told you in past years several times about my work for several years here in our Medina jail, especially when we had open saloons running in full blast in our town. Let me go over it briefly just to bring to mind one particular instance.

Shortly after my conversion I found my way into our county jail. There were, perhaps, half a dozen bad and even wicked men and boys there, shut up with nothing to do but to chew tobacco, play cards, and indulge in the worst profanity and obscenity I ever heard. When I tried in my feeble way to hold up before them the gospel of Christ Jesus they turned on me until I was apparently "snowed under." But I kept coming and pleading with them, not only on Sunday afternoon but between times. When they became tired of their confinement they gradually began to be glad to see me, because it was a sort of diversion to them. I got them to read good books, and taught them to sing some gospel hymns; and as they dropped out one after another they certainly had made some progress out of their evil ways. I met them occasionally years afterward, and almost always with a good report from the seed that was sown in their hearts years before.

After they had all left, the ring leader (who had already served a term in the penitentiary, and was on his way the second time for robbery), I had a chance to get well acquainted with him. In fact, he became so lonesome after many weeks of confinement that he was glad to listen to and talk with anybody.* You will recall,

* After Fred and I became "good friends" I found he was left at an early age without either father or mother, and was "farmed out" from one

perhaps, his coming out of our Medina jail, as the scripture puts it, "clothed and in his right mind." In less than one year he was teaching a class in Sunday-school; and when he got a position as conductor on a freight train he had his caboose papered inside with scripture texts instead of vile pictures and writing, that used to be the custom in years gone by.

The reason I mention this just now is to hold up before you the fact that almost any criminal may be made a good man, or certainly a better man, if some good Christian could sit down by his side, get well acquainted with him, win his confidence, and lend a helping hand in every way in his power. When a man first gets into prison he is often defiant and ugly; but after days and weeks of confinement he sobers down and is ready to talk. What is wanted is good Christian men and women who are willing to give their ability and time to such work. Surely, as we have it in our text, "The harvest is plenteous, but the laborers are few."

Some years ago it was my privilege to listen to that grand good woman, one of God's choice jewels, Mrs. Maude Ballington Booth. The whole wide world knows what she has done for men and boys in the prisons of our land. Well, Chaplain Kiplinger spoke for over an hour. He gave incident after incident showing how he finally reclaimed men who seemed for quite a time hopeless; but, may God be praised, he almost invariably won out in the end. There were such crowds gathered about

farmer to another, and I fear these farmers were more alert in making the boy pay expenses than they were in making a good boy and a good man. As a consequence he became soured toward everybody. He told me that "The world has been 'agin me,' and I am 'agin' the world." That was when I first saw him; and when he declared "They may carry my dead body back to that 'old pen,' but they will never carry me alive," he was in a desperate frame of mind. When I succeeded in making him comprehend the meaning of the text, "Love ye your enemies, do good to them that hate you," he said, "Mr. Root, that may be all right. I do not dispute it, mind you; but it goes awfully 'agin the grain.'" After days and weeks of pleading he finally one day sent word that he wanted to see me. He outlined what a change it would be for him to undertake to be a disciple of the lowly Nazarene, and finally said, "Well, Mr. Root, I do not make any promise, mind you. I do not know how I shall make out *trying* to be a Christian; but I will make a trial of it. I will do the best I can." Then at my suggestion he knelt down on the stone floor of that old jail and in his own way with broken language he said, "God, be merciful to me, a sinner." What a *bridge man* over his face from that time onward! The hard, defiant look was gone. A happy smile lit up his manly face in a manner I had never seen before; and every time we met after that he told me of new victories he had met with the help of the little prayer I taught him—"Lord, help."

him as he ended his talk that I was unable to see him; but after I reached home I wrote him as follows:

My good friend, it was my great pleasure, yesterday, to listen to your talk here in Medina at our Chautauqua meeting. I am enclosing a few leaves of our journal for August 1, to let you know what we are trying to do in the temperance crusade to make Ohio dry.

Now the facts you gave us in regard to intemperance and the state prison are, it seems to me, more important than anything either our journal or the *American Issue* or any other temperance periodicals have gotten hold of. Possibly what you stated has been already in print. If so, will you kindly get it for me, or tell me where I can get it? If it has not been in print I will gladly pay you for your time and trouble in giving me the part of the talk, especially of statistics and figures in regard to intemperance. As I am anxious to know as soon as possible if I can get it for use in our journal, I inclose an addressed postal.

May God bless and strengthen you for what you have already done, and that you may continue the work far into the future. Perhaps I might add that, when I was a young man, for many years I visited our jails here in Medina. That was when we had open saloons in our town, and I had quite a class every Sunday; and it was my great privilege to see quite a number converted to the Lord Jesus Christ, and now filling places of trust and responsibility. You know what this means to a Christian worker.

Once more, may God bless and sustain you.

Your old friend,

A. I. ROOT.

About Sept. 1 I received the following, evidently taken down by some stenographer from one of his lectures:

FROM "THE REMAKING AND MENDING OF MEN,"
By C. L. Kiplinger, Chaplain Indiana State Prison.

Speaking of the parole law and its proven results the speaker said:

The information and advice upon which a parole is granted is gathered for the Parole Board almost from the day the prisoner reaches the institution. The board, considering the release of a prisoner, has before it the full case record of the prisoner's offense; the prisoner's statement; the statement of the trial judge and prosecutor; letters of reference as to the past history, habits, and reputation of the applicant for parole; and, in many cases, the report of a personal investigation made by the state agent.

If a parole is granted, the prisoner must have first of all, a suitable place of employment. This is found or investigated by the state agent. The employer must know that the man he takes comes from prison, be willing to take him notwithstanding, and to take a friendly interest in him. The prisoner must not use intoxicating liquor; he must not frequent questionable places nor associate with questionable characters; he must make each month a written statement of earnings, expenditures, and savings and general conduct, which report must be signed by his employer, vouching for it as correct. The willful violation of one or all of these conditions constitutes a violation of parole for which the man will be returned to prison.

In seventeen years over 8000 men have been paroled from Indiana institutions. Of this great number 75 per cent have kept the conditions of parole, and earned final discharge. In the old days—under the straight sentence regime, with men automatically discharged after having served a stated amount of time, 70 per cent of all men so re-

leased got back into prison within one year for committing some new crime.

The state should itself, by all means, supervise its paroled prisoners. Its agents should know where every paroled man is located, and visit him frequently to advise, encourage, or admonish as the case may need. The paroled man should be as much in the custody of the state as when behind the walls of the prison. Only such an administration of the parole law can make it fully effective, and prevent the law itself from falling into disrepute.

Speaking of liquor and crime, the lecturer said in part:

1. I know that 83.71 per cent of our present prison population are moderate or excessive users of liquor, and trace their crime entirely or indirectly to liquor.

2. To give figures: When our population was 1130 men, 946 of them were either drinking or drunken when their crimes were committed; or their crimes were planned in saloons; or, led away from former standards by drink, they became careless of morals and of law, and were ready to plan or be led into deeds which the law forbids, and for which human society demands a penalty.

3. I know that 96 per cent of the men serving life sentences in the Indiana state prison for murder, rape of child, and under the national criminal act, trace their crimes directly to liquor as the prime or contributing cause.

4. A careful examination into the past history of each of 226 men serving life sentences revealed the fact that 212 of the 226 crimes were traceable to liquor. Except for liquor, 212 of 226 murderers now serving life sentences in prison might now be living at liberty, and free of the foul stain of murder.

5. I know that county option in Indiana did reduce the number of commitments to the prison, and that the facts revealed by a study of the commitments received in a year when 70 of the counties were dry and 22 were wet, are significant as to the effect it would have on crime in our state to abolish the saloon.

Of the 70 dry counties in the state, 27, or 38.5 per cent, sent no man to prison.

Of the 22 wet counties of the state, 3, or 14 per cent, sent no man to prison.

The 70 dry counties of the state during the year committed 92 men to prison.

The 22 wet counties of the state during that year committed 135 men to prison.

The population of the 70 dry counties was 1,597,263. The population of the 22 wet counties of the state was 928,995.

Yet the 22 wet counties containing only 29.6 per cent of the state's population, furnished 55.3 per cent of the commitments to prison.

The 22 wet counties furnished one prisoner for every 7432 of the population.

The 70 dry counties furnished only one person out of every 16,023 of the population.

In one period of six months we received at the prison 92 men. Of these 92 men, 86 came from wet counties and 6 from dry counties. One of the six was insane.

SOUTH CAROLINA DRY, MORE THAN TWO TO ONE.

For days and weeks I have been watching the outcome of the election (Sept. 14) in South Carolina. I told Mrs. Root it would have considerable effect on Ohio, and, in fact, more or less effect on every state that is waging a like war for righteousness. I prayed for South Carolina for days and weeks beforehand. I prayed the

day before election, and on election day; and I kept nervously watching for some intimation of the outcome. Not a word appeared next day in any of our daily papers; not a word the second or third day. I began to tell Mrs. Root that no news was good news, especially when it must come through the dailies that are on the wet side. Finally on Friday morning, Sept. 17, while I was at the Methodist parsonage a good lady informed me she saw something in the papers to the effect that South Carolina had gone dry, without any particulars.

I try to be charitable, dear friends, but I could not help thinking that the great dailies of our neighboring city of Cleveland would show a little more alacrity in giving us temperance news if it were not for the fact that every one of them carries beer and liquor advertisements, that would make it look strange if they uttered a word in the way of rejoicing over a temperance victory, especially at the opening of this mighty campaign here in Ohio. Finally my heart was made glad to find the following on the front page of the *American Issue*, in big letters:

SOUTH CAROLINA VOTES DRY

THE NINETEENTH STATE KNOCKS OUT SALOONS BY A VOTE OF MORE THAN TWO TO ONE.

Tuesday of this week South Carolina voted on state-wide prohibition, and the dries won by more than two to one. The nineteenth state to vote out John Barleycorn will become dry the first of next January. Fifteen of the forty-four counties were wet under the county dispensary system. Early returns indicate that all but one county, possibly two, gave dry majorities. The county containing the capital city of Columbia went dry with a whirl.

South Carolina points the way for Ohio. Let the Buckeye commonwealth become the twentieth state to outlaw the saloon.

Surely God's kingdom is coming.

Later.—The following has just come to hand, dated Columbia, S. C., Sept. 15. I copy it from the *Manatee River Journal*:

South Carolina yesterday adopted state-wide prohibition, to take effect January 1, 1916, according to almost complete unofficial returns gathered here. The vote, with nearly full returns from most of the counties, late last night stood

For prohibition, 33,104.

Against prohibition, 14,157.

The total vote, while well over that cast in most general elections in South Carolina, is far below the customary poll in Democratic primaries. From present indications it seems likely that the total will be in the neighborhood of 60,000.

Governor Manning, who was elected on a local-option platform, after learning the results of the vote, gave out a statement saying that, the people having spoken, he would do his utmost for the enforcement of the law, and would expect the support of all the citizens in his policy.

Of the thirty counties already dry under the local-option law, all gave varying majorities in favor of statewide prohibition, the margin being large in most cases. Only one of the counties now having dispensaries is certainly on the local-option side.

FLORIDA'S NEW TEMPERANCE LAW TO GO INTO EFFECT OCT. 1; SEE P. 474, JUNE 1.

About the time this number reaches you, Florida will be fully ready for law enforcement. If you are not already aware of it, the Davis law is ready to go into effect. See the following, just sent us by the Anti-saloon League of Florida:

FEDERAL JUDGE DECLARES FOR SMASHING THE SALOON.

My notion is that the saloon will have to go. I believe the time will come when the people will rise up and smash the saloon—at least as we have it today. The evidence in this case showed that the saloons were the center of nearly all the corruption in the election at Terre Haute.—FEDERAL JUDGE ANDERSON.

The Davis law will smash the saloon as it is.

Then the Davis law should be enforced, for it allows:

1. No drinks sold or given away—sales to be only in sealed packages.
2. No drinking—no package can be opened in the room where sold.
3. No screens, pictures, music, cards, tables, chairs, or gambling.
4. No loitering—"buy your package and go."
5. No selling to women, boys, drunken men, nor on credit.
6. No free lunch—no eatables at all; the "decoy" gone.

7. No social dram, no treating; profit gone; good by, saloon.

8. No back doors, no dark holes in wall, no back rooms.

9. No selling between 6 P. M. and 7 A. M. Think of it!—the saloon to be closed during the hours when nearly all profits are made.

Verily this law smashes the saloon "as we have it today."

Our next legislature will kill it altogether.

Therefore the Davis law should be enforced.

One hundred and forty-seven liquor-dealers in Jacksonville shall obey the law or else they will plunge Florida into a state of anarchy, holding Florida by the throat, saying, "You can't enforce your laws."

Even the lawyers of the liquor-dealers themselves say that the Davis law is constitutional, and can be enforced. But it is the old story, "The Whisky rebellion."

Let us submit no longer to the rule of rum.

Unfurl the flag and enforce the laws. Let the people rule.

Rally to the help of the Anti-saloon League; and please, as you value our sacred cause, send a check or cash offering to help us pay the expenses of organizing and working committees in every wet city to enforce the Davis law.

We must work fast to get ready for October 1.

C. W. KINNE.

302 St. James Building, Jacksonville, Fla.

BARRING INTOXICANTS FROM THE INDIANS; WHY NOT DO IT FOR THE AFRICANS?

We clip the following from the *Sunday School Times*:

AFRICA'S HORRIBLE BAR-ROOM.

The following item from the *Boston American* illustrates a kind of news which appears every few weeks, and the handicap which we place in the way of Christian civilization while we send missionaries at great sacrifices to advance it. The item ran as follows: "The Estelle Krieger is taking out nearly 300,000 gallons of rum. The demand for rum in

the Dark Continent during the past few months has been unprecedented. The Charles Whittemore sailed June 12, and the schooner Orleans April 22. The three vessels will land nearly 700,000 gallons of the fluid at ports along the west coast of Africa." This is the trade that the Rev. Charles Satchell Morris has said "has turned the entire west coast of Africa into one long bar-room."

Years ago the United States saw fit to pass a law keeping intoxicants entirely away from the Indians. Why it is that a similar law has not been enacted in regard to the colored people, and especially the inhabitants of Africa, is a puzzle. Right in connection with this, from the *Sunday School Times* we make a clipping that also touches on alcohol as a *medicine*. Read it and ponder over it.

DRINK AND SLAVE TRADE IN AFRICA.

Dr. Fisch, for twenty-five years a medical missionary in the Gold Coast of East Africa, writing for one of the European journals, points out that the slave trade as formerly carried on cost the lives of hundreds of thousands, broke up families, and deprived them of liberty; but the injury that the drink traffic has done to the negroes is worse. This Gold Coast country has a favorable climate, and is wonderfully rich in vegetable and mineral products of many sorts; but as drinking has increased, the living conditions and vigor of the people have constantly declined. Negroes who are not drinkers easily recover from pneumonia; but the drinkers die of heart failure in spite of all that can be done. Tuberculosis, once a rare disease, now runs a rapidly fatal course. Degeneracy in the offspring of drinkers is shown not only by their lowered resistance to tuberculosis but by frequent loss by mothers of power to nourish their children, by carious teeth, by a special form of infantile paralysis, and by a considerable increase in idiocy and epilepsy, all of which were formerly rare or entirely unknown. The character of the people also is changing for the worse. Crime and immorality and disease are increasing, and the possibilities of spiritual uplift are being endangered. On the other hand, although the living conditions are much harder in the adjacent territory of the Togo, but where the liquor traffic is prohibited, the people are vigorous, muscular, amiable, and apparently free from degeneracy. "The alcohol trade poisons the race to its roots and menaces its future."

UTAH ON THE WATER WAGON.

My father drank to all that drink calls for; but I had a Christian mother who stayed with us boys until the last, and not one of us drink or use it in any form. I am the oldest, 41, and am blessed with a good wife and five nice boys and one girl. We all enjoy good health, and are ready with our good clear minds and strength to fight the liquor and tobacco habits in any form to the last ditch. Since looking back on my boyhood days I often think of the liquor traffic as it was years ago, along the Ohio River and its small streams. Then there were but very few persons who would dare raise a voice against its use. But to-day I am blessed to see the time when very few will dare raise a voice for it. My mother's last prayer and talk to me about it was, "My son, I may never see the day, but I pray that you will, when a man will be ashamed to uphold its cause;" and, thank the good Lord, it is coming to pass.

We all call you here in our humble home "Daddy Root;" but I do not really think you can comprehend the temperance cause and its effect as well as a man who has seen some of the liquor men's worst

evils. I am hoping and praying that you and all good men and women will live to see the liquor and tobacco evil put out of the way to *stay*, and then may we be able to do better for those who are dear-est to us.

Now, Mr. Root, I must tell you that, in the last twelve years, I have not heard twelve good old-fashioned sermons here in this part of the world. I almost envy you and a great many people who enjoy such blessings. When we get GLEANINGS we first turn to the Home department and read your writings first, and then read it from cover to cover. Nothing is left out.

Remember the mothers in this state can vote on these and every other cause that comes to a vote. Now, if we all will put our shoulder to the wheel and give one good lift, even if we do not lift the load, let us keep on until we do lift it. That is my motto, and I fully believe it is the motto of millions of good people; and so with all of our prayers and votes directed right we can do something for the cause of goodness.

Taft, Utah, Aug. 5.

W. J. JUSTICE.

SHALL THE LIQUOR BUSINESS PREVAIL AGAINST THE UNITED EFFORTS OF OUR SCHOOLS AND CHURCHES?

We clip the following from the Chicago *Advance*:

The saloon forces can never stand against a united attack of the army of Jesus Christ. When we cease to call on God we shall cease to advance. When the United States becomes a saloonless nation we shall have become the best-prepared nation on the face of the earth for war or peace. The multiplication of war munitions and equipment, and the increase of army and navy, will be likely to foment trouble and induce war.

Real preparedness is mental and moral rather than material. A saloonless nation is an invincible nation.

WHISKY AND WAR.

Farming Business hits both of these twin evils a tremendous clip at one blow as follows:

BOOZE IS NOT MEDICINE.

Booze is on its last legs, and they are shaky. The druggists have cleared their skirts of its dirty touch by refusing to include it in the list of drugs and medicines. Reliable druggists have not cared to handle whisky for some time, but thought they were compelled to as long as it was listed in the American drug list. In revising it the last time, however, the committee decided that the ancient fake of calling whisky "medicine" was no longer worth their support. Hence, they put the ban on whisky. The leading medical and scientific men of the world for some time had classed it as poison, and only a stimulant at its best. It was merely a stiff-necked form of hypocrisy to carry it in the drugstores as *medicine* any more. Now the loose supporters are without their main argument that whisky is something that doctors need in their work of saving human life.

As a stimulant and a poison, booze is still a winner. Jane Addams, after her return from Europe recently, where she visited all the monarchs of the warring nations, declared that officer after officer had told her that before a bayonet charge men were given big drinks of alcohol in the form of the various national concoctions in order to "fire them for the killing." Even in war, where men are expected to kill each other if they happen to be wearing different uniforms, they have to be poisoned to kill each other at close range. A bayonet charge

with the storming of trenches where men lock themselves together and clench their teeth and jab with the bayonets until they drop or there are no more moving bodies to jab, requires stimulants. Men must be robbed of their reason for a time to get them to butcher human beings at the ends of their gun-barrels. Such is the rating of booze.

431 MILES OF BREAD.

The value represented in the above heading is what the saloons must take in for beer in one county in Ohio in order to get back the money that they pay the state for the privilege of carrying on the saloons for one year. The *Akron Press* for Sept. 4 prints a copy of a banner that Miss Minnie Ellet is painting by hand to put up at county fairs and wherever they will do the most good. Below is their statement in regard to the matter.

TEMPERANCE WORKER PAINTS BARN TO TAKE WHACK AT JOHN BARLEYCORN.

Old John Barleycorn had better take to the woods. Miss Minnie Ellet, of Springfield, is on his trail again.

Miss Ellet, who has taken many a solid whack at John, is out with a pictorial argument which she thinks is a staggering blow.

The reading below is painted on a huge banner with her own hands. And she is getting ready to display it where she believes it will do the most good.

Miss Ellet has lettered 19 banners, and they are to be presented to as many divisions of the W. C. T. U. in Summit Co.

"Where am I going to put the banners?" echoed Miss Ellet Thursday. "Why, I'm going to put them over the brewers' signs—hang them right over the signs of John Barleycorn."

And below is a copy of the "banner."

SUMMIT COUNTY'S LICENSE BILL.

206 equals number of saloons in county.
\$5 equals application fee of each saloon.
\$100 equals registration fee of each saloon.
\$1000 equals license fee of each saloon.
\$1105 equals total fees of each saloon.
\$227,630 equals total fees of 206 saloons.
4,552,600 equals schooners of beer the 206 saloons must sell to pay just license fees.
Who pays this bill?
One schooner of beer equals one loaf of bread.
4,552,600 schooners equals 431 miles of bread.
To pay just license in Ohio's 43 old wet counties,
11,209 miles of bread must be sacrificed.
Bread or beer?
For which will you vote?

The reason why Summit Co. has such a large number of saloons is because Akron, with a population of 115,000, largely foreigners, is its county-seat. But even *that* county, with its 206 saloons, *voted dry* a year ago.

OUR RECENT OHIO STATE FAIR.

It is refreshing to note that the *Ohio Farmer* feels very much as I do about the improvements recently inaugurated in regard to the Ohio State Fair. See the following, clipped from the *Farmer*:

Expositions are the registers of progress. The State Fair of this year presented strong contrasts with that of ten years ago. Automobiles, farm tractors, road-building machinery, silos and silo-filling machinery, and limestone-crushers and milking-machines are now very prominent. Then the activities of the state itself, the experiment station, the agricultural college, the industrial commission, the State Board of Health, the fish and game, and the dairy and food departments, the livestock and orchard inspection bureaus, made up a very large part of the exposition. This, together with the absence of side shows, gave the fair far more of the educational aspect. The only thing that seemed entirely out of harmony with the education idea was the fireworks. It is hard to understand why "attractions" should be employed at the fair any more than at the agricultural college to draw patronage. It is hard, too, to connect the race track with agricultural promotion or better citizenship. But it may be too idealistic to think of running a fair without a horse race. I hope to live long enough, however, to see it done.

The italics in the above I put in myself. Amen to the closing sentence!

The Ohio State Fair did not take in as much money as in former years; but what they lacked in money at the gate was made up in "treasure laid up in heaven" in the shape of thousands of boys and girls who were not demoralized by low-lived side-shows.

It seems but a few years ago when I saw on the grounds of the Ohio State Fair a long row of beer-kegs with great blocks of ice resting on them. Ice-cold beer was being dispensed alike to old and young, clear through from the beginning to the end of the fair. May the Lord be praised that not only are the kegs of beer a thing of the past, but that the fake beer literature of the "Ohio Temperance Union (?) " has also been put down and out.

NATIONAL APPLE DAY, TUESDAY, OCT. 19, AND THE WAR.

For years past I have been hoping and praying that something might occur to side-track and divert the attention of those engaged in the wicked war in Europe, and that the belligerents would come to their senses and realize the folly of their undertaking; and as, with God's guidance, a pebble from the brook, in the hands of David, slew the giant Goliath, is it not possible that just an *apple* (or a great shipload of apples) may, through God's guidance, do like service in regard to the war "giant" across the great waters.

Mr. R. J. Coyne, chairman of the Publicity Committee of the United States, sends us the following:

APPLES FOR SOLDIERS IN EUROPE.

"Last year they let several cargoes of toys and other similar articles go through to different countries, and I think these apples ought to be consid-

ed in the same light as other gifts which America has donated to the war-ridden countries."

A local apple-man who has interested himself in the matter, and who has figured out how it can be done, says: "It is a big proposition, and will require skillful handling; but it can be done. The value of the fruit alone would approximate about \$300,000 aboard ship at New York, for apples are worth considerably more than a year ago. Of course the expense of outfitting a vessel is a matter that has not been fully decided upon, but the fruit people have always been charitably disposed in cases like this, and they will help to find the means if assurances are given that the apples will reach proper hands. We understand that there are about 25,000,000 men actively engaged in the various armies and navies in the European war, and probably as many more indirectly involved. To give them all an American apple apiece would mean at least 50,000,000; and taking 500 apples to the barrel, which would be medium-sized fruit, we shall have to provide 100,000 barrels or 300,000 boxes, at the lowest estimate. At present the minimum market value of this fruit is \$3.00 a barrel. I figure the whole undertaking would cost not less than \$500,000; but when we stop to figure that every person in this country, no matter what his nationality may be, could easily lend a hand in the undertaking it is not such a difficult proposition as one might suppose."

Apple-men hope to have the European belligerents agree upon a one-day armistice when the apples are distributed, and it is planned to get everything in readiness for the vessel to sail on National Apple Day, Oct. 19, so that the consignment may reach the various fighting zones and hospitals the early part of November when Europe's scant fruit supply will have been exhausted for this season.

Every soldier in the trenches and hospitals in Europe will be given an apple in the near future, it plans now being worked out by a committee of the apple trade throughout the United States are successful.

It is proposed to have a vessel take over a big cargo of apples to be distributed free under the auspices of the Red Cross, and efforts will be made to get President Wilson and Secretary of State Lansing to have the several warring governments permit safe passage for portions of the big consignment to the various fronts and hospitals where the fruit can be placed in the hands of the Red Cross for distribution, especially among the sick and wounded.

Apple growers and dealers who are endeavoring to send over the big consignment have learned that many of the fighting men are suffering because of lack of fruit juices, giving rise to scurvy and other disorders. Returning surgeons who have seen service in the European hospitals are said to approve heartily the plan to provide more fruit juices, not only among the wounded but also for the men in the trenches.

"We are working on this undertaking purely from humanitarian motives," said one of the committee who is a leading wholesale apple distributor, today. "It's going to cost a lot of money for the fruit alone, and we shall call upon all the people engaged in the apple industry to contribute a portion of the expense. At first the trade did not take kindly to the plan, as it was feared that vessels could not be found to carry over the apples. Then the idea was conceived of chartering a ship which would take nothing but apples; and we believe that when the purpose is disclosed to foreign governments none will oppose free passage of our ship, for it will go on a mission of charity.

R. J. COYNE (of Coyne Bro's, Chicago),
Chairman Publicity Committee.

Please notice the italics in the letter

above. If the belligerents could agree on this one-day armistice, might it not open a way toward ending the war at once and for ever? Jane Addams, who is now at the seat of war, says the only difference between the men who are fighting is the difference in their uniforms.

Our good friend Coyne sends with the above letter a list of about 75 fruit-dealers and commission men, located in as many of the principal cities of the United States, and, as I understand it, these great commission firms, and every one else, are going to work to load a ship with apples, this ship to sail Oct. 19.

CRIME A DISEASE, ETC.

From away off in Honolulu comes a periodical called *The Friend*; and this little magazine is indeed a friend of humanity. See clipping below from *The Friend*:

CURING CRIME.

Mr. Osborne's splendid management of Sing Sing prison is concentrating the best thought of the country upon the newer methods of restoring criminals to health as productive members of society. In three and a half years Warden Homer at Great Meadows, in New York, has been conducting his prison farm with such success that of 1400 paroled men only 40 have been returned to confinement. This system of treatment has been tried elsewhere with like results. Hence it is not strange that New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Minnesota, and Virginia are already embarking upon similar experiments with prison farms, and not a few other states are finding that outdoor work for prisoners under right conditions gives the most gratifying results. Hawaii has been practicing the same method for years and with great acceptance. Though we have no prison farm our wardens have been most successful in utilizing outdoor work as a means of training men back to normal habits. In this connection Mr. Ford of automobile fame has rendered the country lasting service by his graphic declaration of his willingness, after careful experimentation, to attempt in his factory the reformation of any criminal. Crime is now recognized as a social disease, no case of which can be pronounced incurable. The next step is to train social physicians to become experts in the treatment of this malady, and then to intrust all patients to their care. Meantime side by side with this procedure social hygiene must be employed to counteract the unsanitary social conditions amid which this disease is generated. This is a long task, but it is as sure of success as Dr. Gorgas was in rooting out yellow fever from the Panama canal zone by exterminating the *stegomyia calopus*.

After intoxicants have been banished from Honolulu and every other spot on the face of the earth, a great part of the crimes of the world will be banished. And if criminals can then be treated by good men and women in the different states and nations we shall have gone a good way in showing the world that "God's kingdom" is coming.

The clipping above comes right in line with the work done by Chaplain Kiplinger, mentioned in *Our Homes*.

HIGH-PRESSURE GARDENING

SPINELESS CACTUS, ONCE MORE; WHAT OF THE FUTURE?

By comparing the picture adjoining with the two pictures shown in our issue for Aug. 15, you will notice the growth in 29 days has hardly been equal to that made in nine days the last of July. Very likely the slower growth was due largely to the excessive rain. In fact, it has rained almost every other day, and sometimes *every day*, clear on till near the middle of September. We learn from good authority that so much wetness is pretty sure to pro-

I shall pull off the new slabs and pack the whole plant so as to take it in my trunk down to Florida. My impression is, these slabs can be kept several days or even weeks without impairing their vitality. In fact, we are told that the slab starts better after being kept out of the ground so as to become somewhat wilted.

SOMETHING ON THE OTHER SIDE OF SPINELESS CACTUS.

In a recent issue of the *Florida Grower* appeared an article by Fred N. Burt. Mr. Burt became enthusiastic about spineless

The spineless cactus (pictured on page 691, Aug. 15) 29 days later. Photographed Sept. 2.

duce rot; but in order to *obviate* the effects of so much wetness I dug a ditch or trench and piled the dirt up around the cactus so as to form a sort of pyramid. Then I made a ditch to carry off the surplus water; and I am inclined to think, especially on heavy clay soil, like that of our *Medina* clay, the cactus should be planted on a ridge, very much as they grow sweet potatoes in the South. So far I notice no tendency to rot. Should frost occur I expect to cover the plant with canvas; and when it becomes severely cold, toward the first of November,

caeti; visited Wyoming, Colorado, New Mexico, Arizona, and California; talked with Burbank himself and other promoters of caeti; and although Burbank told him he feared it would not succeed in Florida on account of so much rain, he pushed ahead in his project of growing caeti for beef cattle in Florida. He even went so far as to purchase toward a thousand slabs comprising the best varieties. Below is an extract from what he says about it:

They were received by me in splendid condition at DeLeon Springs, Florida, on April 9, 1914, and

placed on high, dry, sandy soil. Every instruction was carefully followed, and for the next sixty days the plants seemed to prosper. Then, slabs commenced to show rotten spots; and on opening them up we found they were filled with soft white worms resembling a maggot. The outside edges of the slabs were also attacked by a hard hazelnut-shaped bug which bored holes along edges.

We used a solution of arsenate of lead spray, whale oil, sulpho-tobacco, and other sprays without results; have carefully and frequently examined plants and destroyed the pests; have written to every one whom we thought might suggest a remedy, but without securing any relief. The entire field is now just about finished, and I expect soon to plow under what little is left.

None of the promoters of spineless cacti admit that this plant has any insect enemies—in fact, I have observed advertisements that stated that it has no insect enemies. The rainfall in Florida is more than twice the amount Mr. Burbank stated it could ordinarily stand. While in California I was not told that experiment after experiment had been tried in Florida, and was allowed to believe that I was a pioneer.

have been a feature of that particular locality. Another thing, in starting any new crop, whether it is celery, strawberries, corn, and I might almost say *wheat*, in any untried locality, there are usually more failures than successes. In fact, there are failures everywhere. Look about you wherever you may be located; take a trip on the cars, and see how many failures there are to one real success, and see if it is not true that it is largely in the man (or boy) who goes at it. I am not going to try to grow cactus on a large scale; but I expect to try to grow enough to give my chickens green food; and I will try to give you some pictures as I go along. One thing I have spoken of already is that spineless cactus in Florida and here in Ohio can be *made* to make an astonishing growth in just a few days or a few weeks.

Dasheens in Dayton, Ohio.

The Agricultural Experiment Station at Gainesville, Florida, states, April 2, 1914, that "Spineless cacti planted in the state in the last six or eight years have all gone to the bad. It seems that the spineless-cactus salesmen have been the only ones who make anything out of this."

Perhaps most of the friends would think that after the above report I would give up thinking I can grow cacti with profit in Florida; but let us consider a moment. This man went in on a large scale the very first thing; and I would urge, and have urged for years past, that no one should undertake to keep bees, chickens, or grow any crop, especially in a new locality, until he has first experimented on a small scale. Do not go in heavily on any new thing to start with. The main trouble mentioned in the above is the insect enemies, and these may

"THREE CENTS AN HOUR;" DASHEENS IN OHIO;
REMEDY FOR CUCUMBER-BUGS; IS IT EVER RIGHT
TO GO TO WAR?

Dear Bro. Root:—Although I am out of the bee business I want the journal for Our Homes, etc. I read several times over the May 15th issue. It alone is worth the price.

I want to say a few words about your paying boys three cents an hour years ago. Well, when I was 14 years old I hired out on a small farm for \$2.50 per month for seven months. I went to school five months without pay—only my board. I bought my own clothes. The fifth year they paid me \$4.50 per month. At 19 I set in to learn the shoemaker trade. I served three years as apprentice; got (big pay, of course) \$16, or \$48 for the three years, board and washing included. I saved my money, and always had a little for the Sunday-school basket. Some of you young kickers don't know what your fathers had to contend with. Common laborers received 75 cts. to \$1 per day, and raised their families too.

Last summer my grandson took a snapshot at my front yard where you see the dasheen and your

humble servant. They were just 41 inches high. I had a fair yield; ate some of the bulbs, and found them very good. I did not use the stalks or leaves. I had it as an ornament in the front yard. I have no room in my back yard.

Some years ago I had planted quite a lot of cucumber seeds. They came up nicely; but one day the striped bugs came by the hundreds. The creek bottom being close I went down and pulled up a big armful of spearmint. Some call it peppermint; but it is spearmint. I dropped a bunch of the mint on each hill, and went home. Next day there was not

a bug about. I did not bother any more that year, and the green mint kept the ground moist several days.

Now about the war. I agree with you in your answer to the young man (Mr. Gibbon). I carried the musket in our Civil War 50 years ago. While I am for peace, yet, old as I am, if the flag demanded it I would shoulder the musket again. If I could not stand up I could lie down to it. May the good Lord bless and keep you in good health many more years is my prayer.

Dayton, O.

H. BRENNENAN.

HEALTH NOTES

DEAFNESS—THE BORACIC-ACID REMEDY.

Since the article in the July 1st GLEANINGS appeared, exposing, as I supposed, an intended humbug and fraud in regard to "enserol," I have had quite a number of letters something like the following:

Mr. Root:—My wife has become interested in what you have to say about the use of boracic acid in GLEANINGS for July 1. She is bothered with a roaring in her head, and wishes to try the treatment named, and would like to have you tell just how to use it—whether warm or cold water, and about what proportion or strength to have the wash. Also how often.

Bates, Ark., Aug. 2.

H. C. BETHEL.

I wish all the friends who want to know all about this matter would hunt up GLEANINGS for September 15, 1914, as that gives all the information I am able to furnish. The directions I copied from that "woman's story" I give again as follows:

This is a copy of the prescription given me:

Pure glycerine, $\frac{1}{2}$ ounce; fluid enserol, 1 ounce; boiled water, $2\frac{1}{2}$ ounces. Mix.

Put one drop in both ears, night and morning.

Wet the forefinger, and rub the solution full strength, behind and below the ears.

Four ten drops of solution in one-fourth glass of warm water, put some in palm of hand, and snuff up the nostrils, night and morning; also gargle the throat with the same strength solution as used in the nostrils, night and morning.

But instead of buying the expensive enserol, use boracic acid. I think your druggist should be able to tell you about how much.

Here is something from one who has been a good friend of GLEANINGS for many years that seems to be a sensible explanation for the roaring in the ear:

Mr. Root:—The "roaring sound," as it is commonly styled by those who experience difficulty in hearing, is not an indication of deafness, but that the drum of the ear is still in a healthy condition, and that the passage from the outside to the drum has become closed with wax-secretions, preventing sound waves reaching the drum, which in its muffled condition will then record the faint sounds made by the blood as it surges through its veins. A similar effect is obtained by a healthy ear being covered by the shell of a sea comb.

Procure a water-bag with a piece of hose attached; or, if you can, obtain a small jet of water in any other manner. Have some one direct the jet over the ear for a minute or so, when the lumps of

wax will come out, sometimes tubular pieces the size of the ear in diameter, and an inch long. Water will do this work splendidly, and there is absolutely nothing gained by using drugs.

Lake Roland, Md.

BENJAMIN B. JONES.

Before receiving the above letter I had satisfied myself that the roaring was caused by some of the "machinery," if you will excuse the word, in the patient's body; and I rather decided that the coursing of the blood had something to do with it. Friend Jones suggests that pure warm water may be as good as the remedy. I am inclined to think, however, that the boracic acid and glycerine more thoroughly cleanses the nostrils, throat, and ear, than pure water alone.

I used it according to directions twice a day for a month or more; and the passages between the ear, throat, and nostrils were certainly cleansed better than I had ever been able to get them before; but I cannot detect any improvement in my hearing. Some years ago I sent to some doctor out west for an apparatus and medicine to restore hearing. He advertised "no cure, no pay." A part of his instructions were a systematic massage with the fingers around the ear, throat, etc. After following his directions I decided there was at least some improvement in my hearing, and I sent him the five dollars. I think I wrote him that my opinion was that the massaging had more to do with the improvement than the medicine. A year or so ago a good lady somewhere in the East wrote me she thought I could get help by giving my face around the ears a good rubbing with the fingers twice a day or more; and she gave minute directions how to do it. If she should see this and will kindly give it again I shall be glad to publish it. I have lost her address, and therefore cannot find her kind letter just now.

Friend Jones suggests that the roaring is caused by the passages being stopped with earwax, etc. But the enserol and glycerine will remove all accumulations in the ear better than anything else I know of. At the present time I have not noticed any

roaring for some time back. I think it is more apt to occur when I catch cold.

Let me suggest in closing that a thorough cleansing and washing of the whole body every day is certainly a good investment of time—much better than depending on drugs of any kind. Let me say again that I give my whole body a thorough washing every day of my life, and this includes eyes, ears, throat, teeth, and everything else; and in washing my head I devote extra time to massaging with my fingers all around my ears and throat in order to stir up to activity as much as possible these useful and important adjuncts to the enjoyment of life. After being thoroughly washed and rubbed, while free from clothing or other obstructions, I swing my arms and go through with my physical exercises I have before mentioned, so as to get up an appetite for breakfast; and after I get dressed up I feel in excellent trim to go out and hoe in the garden until Mrs. Root pounds on the window. About that time I am in good shape for *breakfast*, you may be sure.

THE PATENT-MEDICINE BUSINESS AND QUACKERY.

I hold in my hand a 24-page pamphlet sent out by the American Medical Association, of Chicago, entitled, "At the Bar of Public Opinion." This pamphlet quotes from thirty to forty leading periodicals in regard to the patent-medicine business. Among them are *Collier's Weekly*, *Harper's Weekly*, *New York Tribune*, *Burlington Hawkeye*, *Chicago Daily Tribune*, *Labor World*, *Cleveland News*, and the *Rural New-Yorker*. We quote from the latter:

When all publishers realize, as all will be forced to realize, some day, that they cannot retain the respect of their readers and print sermons on one page and advertisements of fake medical nostrums on another, there will be less need of government supervision over journalistic enterprise. The very fact that "a sick man will try anything to get well" places an obligation upon publishers which they can no longer afford to ignore.

It seems the whole wide world is waking up to the waste of money and damage to health that comes from the drug habit or from answering some newspaper advertisement instead of consulting a family doctor or some educated physician who has the reputation of being a good honest man. The editor of the *Rural New-Yorker* made use of this expression in a private letter received a few days ago:

The idea of doctoring a man by mail, never having a chance to see him or examine him personally, has always struck me as a fool proposition.

Of course the quacks and patent-medicine venders say the doctors are against them because it injures their business; but

I think this is a mistake. Much of the business, especially the serious and difficult business that our doctors have to meet, is the patient who is seemingly beyond recovery from the use of stimulating or habit-forming drugs. I know something about the matter, for a near and dear relative found she could not go on with her work in the office without the use of headache powders; and she kept on using them until she was suddenly stricken down; and in spite of all the aid a competent physician could give she died in just a few hours. Why, I am ashamed to confess that, years ago, we kept headache powders in our store, so that any of our help in any of the different departments could go on with his work by using headache powders when otherwise he would have to go home and take a rest.

This same pamphlet I have mentioned contains a list of leaflets exposing and explaining the various medical fakes such as cancer fakes, consumption-cure fakes, epileptic-cure fakes, medical institutes, mineral waters, oxydonor and similar fakes, san- atogen, cure for drinking, smoking, etc.

Just a word about cancer and consumption. I believe that the general opinion of those who are best able to judge is that *every medicine advertised* to cure cancer and consumption is a fake. Of course all these diseases may often be cured, but the cure does not come from the stuff that you get out of a bottle. Consumption is cured by getting in the open air, getting interested in something that not only occupies the mind but the body as well—every muscle of it if possible. A few years ago a man who was pronounced incurable by the doctors on account of consumption took it into his head that he could go to California on foot. When he started out he could walk only a short distance without resting. But he had pluck enough and faith enough to keep on; and he soon discovered that he could walk a little further every day than he had done the day before. In this way he got well and strong.

Down in Florida you can find almost any number of people who got well after the doctors had given them up by going down there and keeping chickens, bees, or making garden. They simply got busy and happy with something that kept them *outdoors* under's God's blue sky every hour of the day. Some of them not only worked outdoors but slept outdoors and *ate their meals* outdoors. When the world wakes up to the fact that this is the only way to get well, the venders of stuff put up in bottles will be driven to some other method of making a living.

A New Model Typewriter

The No. **9**
OLIVER
The Standard Visible Writer

BUY IT NOW!

Yes, the crowning typewriter triumph is here!

It is just out---and comes years before experts expected it. For makers have striven a life-time to attain this ideal machine. And Oliver has won again, as we scored when we gave the world its first visible writing.

There is truly no other typewriter on earth like this new Oliver "9." Think of touch so light that the tread of a kitten will run the keys!

Caution!

The new-day advances that come alone on this machine are all controlled by Oliver. Even our own previous models—famous in their day—never had the Optional Duplex Shift.

It puts the whole control of 84 letters and characters in the little fingers of the right and left hands. And it lets you write them all with only 28 keys, the least to operate of any standard typewriter made.

Thus writers of all other machines can immediately run the Oliver Number "9" with more speed and greater ease.

Warning!

This brilliant new Oliver comes at the old-time price. It costs no more than lesser makes—now out-of-date when compared with this discovery.

For while the Oliver's splendid new features are costly—we have equalized the added expense to us by simplifying construction.

Resolve right now to see this great achievement before you spend a dollar for any typewriter. If you are using some other make you will want to see how much more this one does.

If you are using an Oliver, it naturally follows that you want the finest model.

17 CENTS A DAY! Remember this brand new Oliver "9" is the greatest value ever given in a typewriter. It has all our previous special inventions—visible writing, automatic spacer, 6½-ounce touch—plus the Optional Duplex Shift, Selective Color Attachment, and all other new new-day features.

Yet we have decided to sell it to everyone everywhere on our famous payment plan—17 cents a day! Now every user can easily afford to have the world's crack visible writer, with the famous PRINTYPE, that writes like print, included FREE if desired.

TODAY---Write for Full Details and be among the first to know about this marvel of writing machines. See why typists, employers, and individuals everywhere are flocking to the Oliver. Just mail a postal at once. No obligation. It's a pleasure for us to tell you about it.

EDITORIALS

Our Cover Picture

THE picture on our cover shows an apiary near Oak Point, Wash., belonging to Mrs. L. Schmitt. Mrs. Schmitt, since the death of her husband, has been managing the yard herself with the help of a hired man.

The hills back of the apiary look like burnt-over timberland. As might be expected, the willowherb, or fireweed, as it is called (*Epilobium angustifolium*), is the chief honey plant, the main flow coming in July and August.

The Smoke Method of Introducing Not an Unqualified Success

FOR some reason the smoke method has not proven to be as successful this year as last. Whether the season has had anything to do with it we cannot say. However, in our own apiaries we have gone back to the cage method, which, all things considered, seems to be the most reliable. We do use, however, the smoke method of introducing virgins. But most virgins are allowed to run into the entrance of the hive when a day old, care being taken not to allow them to come in contact with the fingers. This method of introducing is used mainly with nuclei and not with full colonies.

Aster Honey—when it Can and Cannot be Safely Used for Food

It came to our knowledge a few days ago that one of the old veteran beekeepers who has used a great deal of aster honey as a winter food in years past has found that this honey is perfectly safe when it is *all sealed*. It is when much of it is unsealed, according to this same veteran, that it brings on dysentery and death to the bees. When he finds much of it unsealed because the asters have ceased to yield nectar he forces the bees to fill the cells, and cap them over by feeding sugar syrup. In this way

the bees consume sugar stores first, and later on well-ripened aster honey.

It is safe to say that sealed honey of any kind is better at any time than unsealed. The same can be said of sugar stores.

Death of Another One of the Veterans

JUST as we go to press we learn that Mr. H. R. Boardman, of Collins, Ohio, the man who had the reputation for many years of never losing any bees during winter, passed away Oct. 1 at the ripe age of 80 years. Quite fortunately we had prepared a little sketch of his life before he died, and it appears on page 322 of last year.

Mr. Boardman was one of the best beekeepers in the United States—one of the early advocates of sweet clover as a forage plant for bees as well as stock, and a man who seemed to have the faculty of wintering bees year after year without any loss. He also was the first to show that the sun's rays, when properly applied, would prevent the granulation of honey.

He was a keen observer, a successful honey-producer, and occasionally wrote for these columns in years gone by.

So it goes. One by one the veterans are leaving us.

Filtering Honey

DARK honeys in general do not sell as readily as clear water-white honeys, such as alfalfa and white clover. An inexpensive method of filtering and refining extracted honeys like buckwheat and aster is being sought by the Federal Carbohydrate Laboratory in Washington. The laboratory workers have passed dark-colored honey through bone char and secured a product as clear as crystal.

The only drawback to a general employment of this method of filtering is that the cost of bone char is about \$60 a ton. Ordinary charcoal is cheaper, but not so effective.

tive. With the co-operation of the Forest Service the Laboratory is now looking for a cheap wood charcoal which will take out the color, and experimenters believe that they will soon find it.

If such a process of filtering dark honeys and syrups can be made so cheap as to become available to the ordinary honey-producer, a great deal of honey which has been going for manufacturing purposes, or has been fed back to the bees, can be placed directly upon the retail market. There is still a question, however, whether such a process could ever be made so cheap as to bring such honeys as the inferior tropical grades into competition with the best white clover, sage, and alfalfa, now on the market.

=====

Ohio State Convention

THE Ohio state beekeepers will meet in convention at Akron, O., Nov. 26, 27. Dr. Phillips has promised to be present and give an address; and it is expected, also, other prominent beekeepers from outside the state, as well as those locally, will participate on the program.

Akron is the home of the rubber industry of the United States, and an opportunity will be given for the members to go through one of the big rubber plants, and possibly visit the Barber farm, owned by O. C. Barber, the match king. Mr. Barber has a model apiary on his place. Further announcements will be given later.

=====

Nosema Apis, Bee Paralysis, or What?

SINCE our editorial on page 784, Oct. 1, we have received quite a number of letters from subscribers, telling of the peculiar malady which has come and gone, but which does not quite tally with the symptoms given for bee paralysis. The presumption is that it is nosema apis; but if it is not that disease it is evidently the same thing that has wrought such destruction in the Mississippi Valley northward in Wisconsin, and up and down the Pacific coast. The following letter from A. R. Miner is a fair sample of some we have been receiving:

I am writing to get some information. For the past two years I have noticed my bees dying off at intervals. The disease is something similar to paralysis, but I do not notice any swollen condition. The bees seem rather to shrivel up. For three or four days they will die by the thousands, then all of a sudden they will seem to be all right again. I have noticed that they die mostly when cool days hinder their flying in fall and spring. Some hives are not affected, while others beside them become so weak that they make scarcely any surplus honey.

I have sent some of the dead bees to Washington, D. C., and received the reply that they could not tell from the bees sent what was the matter. I thought perhaps you could help me. If you can, it will be greatly appreciated.

Fowler, Cal., Sep. 28.

A. R. MINER

We shall be glad to get an exact description of the disease that has been killing bees this summer in the different localities mentioned, or anywhere else in fact. We do not care for letters describing a mild form of bee paralysis; but what we do desire to get is a description of the malady that is killing so many thousands of bees, in some cases resulting in the almost complete destruction of the entire colony.

=====

J. E. Wing, Apostle of Alfalfa

ANY one who knows alfalfa knows Joseph E. Wing. The spread of alfalfa in the states east of the Mississippi has been due more to his work than to any other cause. His experiments at Woodland Farm, his articles in the agricultural press, his lectures, his books, make him the most prominent authority on alfalfa in the United States, and that at once interests western beekeepers, so closely are their interests tied up with the prosperity of alfalfa.

Joseph Wing died Sept. 10 at his home in Mechanicsburg, Ohio, at the age of 54 years. "Alfalfa in America" was his best-known work, the one which made him famous. He wrote three others, "Sheep Farming in America," "Meadows and Pastures," and "In Foreign Fields." In all of them his charmingly intimate style is the delight of readers.

There is no branch of agriculture in this country but has felt the impress of his brain and hand. Not a beekeeper, his contribution to beekeepers in publishing the gospel of alfalfa and sweet clover has never been fully appreciated by them.

=====

A Word of Warning in Marking the Minimum Net-weight

WE have learned that quite a number of producers are marking all their comb honey with one rubber stamp reading "Weight not less than 6 oz." A larger number are using a stamp, "Not less than 10 oz. net." They put all their honey in a shipping-case indiscriminately, marked in the same way.

The fact is, ordinary good comb honey produced with separators runs anywhere from 10 to 12 ounces minimum. We have learned from high authority that the federal Government considers low marking of comb honey as a serious contravention of the

law, and that parties that are marketing their product in this way will probably be subject to the regular penalties.

The Bureau of Chemistry has ruled that when the minimum net-weight principle is used, it must indicate as nearly as practicable the actual weight of the section. To mark every section "6 oz." defeats the *very intent* of the law, as can be readily seen. Technically it may comply with the law, but in spirit it does not; and Uncle Sam has given us the word that unless the practice is discontinued he will hold the guilty parties severely responsible.

Increasing the Demand for Honey Cakes; a Suggestion to our Readers

If every reader of this journal would take pains to inquire for honey cakes or cakes that contain honey at the local grocery, it would increase the demand for honey foods enormously. Enormously, did we say? Yes, providing *every* reader does make these inquiries. The grocer will put in a larger stock and make an effort to push the goods.

Most of you have honey for sale. Why not increase the demand for honey cakes and thus, of course, the demand for medium grades of honey used for cooking and baking?

Then why does not somebody put up a canning-factory using honey as a sweetening agent? The honey business and the fruit business depend on bees. Why not build up both lines so there will be a larger demand for honey? Fruits canned in honey! The very suggestion sounds good and is good.

The Ontario Crop Report Again

ON p. 698 for Sept. 1st we gave Mr. Morley Pettit credit for the complete honey crop report issued. Referring to this he begs leave to make some corrections. He writes:

Mr. Root:—I wish to thank you for your kind words in editorial, page 698, on crop reports in Ontario, but feel like making one or two corrections.

The credit for the work of crop reporting in Ontario is due more largely to the committee—Messrs. Wm. Couse, H. G. Sibbald, and W. J. Craig, than it is to the secretary, in that the work was inaugurated in 1903, when the present secretary was a very junior member of the Ontario Beekeepers' Association. Then, while the report is from 19,107 colonies, it is from only 300 members, and is valuable for averages, but not for totals. I would not go so far as to say that this report gives much of an idea of the amount of honey in sight in Ontario; at least, we are far from satisfied with the fact that only 300 out of about 1400 members reported, and that there are at least six or seven

thousand beekeepers in Ontario who are not even members. It is true, however, that this annual report has been of great value in standardizing prices of honey. Dealers have come to watch for this report with the same interest and confidence as beekeepers, and some have gone so far as to become members of the Association, so as to be sure of receiving our publications regularly.

The "Dark-honey-crop Report" recently issued, a copy of which I am enclosing, shows that, in spite of the depression, owing to war conditions, honey is selling freely, and is going to be looked upon by many as being as much a necessity as fruit, at least.

Guelph, Ca., Sept. 14.

MORLEY PETTIT.

A Manual of Bee Husbandry for New Jersey

THERE has just been issued by the New Jersey State Board of Agriculture a book on bees, of 72 pages, by Elmer G. Carr, deputy of the State Entomologist in bee-inspection work. The conditions in New Jersey are quite peculiar. There are almost no large beekeepers in the state, and the flora is comparatively limited; but according to Mr. Carr's manual the industry can be very materially developed. Instead of averaging only 14 lbs. per colony it would be possible with a better knowledge of bees to secure nearly 50 lbs. In fact, this bulletin was issued in order that a "more thorough and widespread knowledge of the general principles of good bee management" might be available.

Mr. Carr is a good beekeeper, and, so far as we have been able to go over his work, we have found it correct and orthodox in its teachings. It was prepared with special reference to conditions in New Jersey; and every beekeeper in that state, at least, and, in fact, every farmer and fruit-grower in New Jersey, should secure a copy. We presume it can be obtained by residents of the state by a mere application to the State Board of Agriculture, Trenton, N. J. Ask for Bulletin of Bee Husbandry by Elmer G. Carr.

The Abuse of "Bait Sections," the Danger of Feeding Back to Finish up Comb Honey

A LARGE buyer of honey recently told us that many comb-honey producers are making a mistake in allowing their "bait sections" to go in with the rest of their comb honey that is sent to market. These "baits" are always inferior to the combs produced on foundation, built out, filled, and capped the same season. The great trouble with the "baits" is that they granulate almost immediately after they leave the producer's hands; and a section of granulated honey

in a case of good honey is almost sure to knock the price of the whole case clear down.

After the producer sells a large shipment of comb honey, the honey is out of his hands. The buyer turns around and complains that he has found granulated sections in many of the cases. Fearing that every section will granulate like the "strays" he has seen, he will knock off a cent or two from the agreed price "because the honey was not as represented." Producers should always put the baits by themselves, and sell them locally if possible; but under no circumstances put them with the rest of the comb honey.

The producer can hardly avoid the use of bait sections in the first super; but there will be no need of using them in a second, third, or fourth super. Let us suppose the producer has a crop of three supers per hive. One-third of the supers would have a single bait. That bait shows up wrong almost at the start, and the result is that the buyer when he finds it in a nice case of honey is afraid of the whole shipment, and he pays accordingly. Possibly the beekeeper might recover by bringing suit, but it would never pay him to go to court when only a cent or two is involved, so he would take what he could get.

FEEDING BACK TO COMPLETE UNFINISHED SECTIONS.

This is practiced by some of our best producers: but the product is always inferior to the regulation comb honey. Even if one uses very light-colored extracted to finish out some of his sections, the product when it appears in the section is darker than the rest of the honey. We do not know why this is so, but it is so. Buyers nowadays are becoming very discriminating; and it is our opinion that all fed-back sections as well as baits should be sold around home. Never mix them with the other comb honey for the general market.

Can You Beat it?

WE have a letter from William Lossing, of Phoenix, Arizona, one of the largest honey-producers in the country, in which he says he has loaded what he believes is the largest car of honey that was ever shipped. He had an order, he explains, for a carload of honey—"the larger the better." He accordingly secured the biggest car he could, and crowded in 646 cases, or a total of 87,589 lbs. The average car does not go above 40,000 lbs. If any of our customers or subscribers have ever been able to beat this, let them speak out.

Incidentally it may be well to remark that there might be considerable danger in making such a heavy load of honey as this. Many of the western cars have a capacity of 100,000 lbs., and these weights carry with them permission to add 10 per cent more. It is evident that our friend, unless the car was a very large one, must have piled these cases clear up to the ceiling in the car. The bottom cases must, therefore, have had an enormous weight on them. Moreover, such weight, subjected to the violent jerking, backing up, and starting of a whole freight train would be almost sure to cause leakage in the bottom cases. Unless one takes a ride on a freight train he can have not the least conception of the fearful pounding that a freight car receives.

Taking everything into consideration, we question the advisability of loading so large a car with honey. One might pile in pig iron, wheat in sacks, and other commodities, and the danger of loss would be comparatively slight.

We shall be interested in learning how this car got through.

The Freight Classification Committee's Designation of Comb Foundation as "Bee Comb."

A SUBSCRIBER has written us a vigorous protest against billing comb foundation in express and freight shipments as "bee comb." He says he has observed that railroad men have the impression that this is artificial comb, because it is sold by the bee-supply manufacturers to the beekeepers, and he thinks it is high time we should stop fanning the flame of the artificial-comb-honey-canard.

We have written our correspondent that the supply manufacturers had nothing to do with the term adopted by the Railroad Freight-classification Committee, and at present they are powerless to affect the change. These people do not know what comb foundation is, and therefore put into the classification a term which to them expresses what the article is; but the trouble is, it expresses altogether too much.

We suggest that, when the classification committee meets again, the manufacturers of bee supplies, especially the makers of comb foundation, request the elimination of the term "bee comb" and substitute the usual term of comb foundation, for that is the term that exactly expresses the name of the article itself.

We shall endeavor to give an announcement when this classification committee

meets again, and will then request that our subscribers pour in a mass of letters to the committee, explaining why this peculiar designation on the part of the railroad companies is doing harm to our industry. A systematic, united, and concerted action on the part of all parties interested will bring about results.

There is another reason why the term "bee comb" should be eliminated. Real honey-comb would be more expensive and much more fragile—that is, more subject to damage than comb foundation. If the railroad companies have an idea that the article is exactly what it purports to be, as shown by the name "bee comb," and they probably do, they would charge a higher rate of freight. From an economic standpoint beekeepers and manufacturers alike should seek to get another form of billing that will help us to get a lower rate of freight. It is excessive as it is.

Granulation of Honey Hastened by a Wide Variation in Temperature

We quite agree with Mr. Holtermann in what he says on this subject, p. 799, last issue. Some years ago, during very cold weather, we conducted a series of experiments in this matter. The winter was very severe, and for over six weeks the temperature ranged around zero outdoors, much of the time below.

We placed some liquid honey in a building where there was no artificial heat. This was left undisturbed during the entire winter, but it did not granulate till toward spring. We also placed some of this same lot of honey under conditions of *varying* temperature. Part of the time the mercury went down below zero and part of the time up to 80 F. We tried to have as much variation as possible with low dips, every now and then to below zero. In the course of ten days cloudiness appeared, and in a month's time granulation was complete.

Another lot of this same honey we kept in a *uniform* temperature of 70 to 80, but it did not granulate the whole winter nor next spring. The following spring, when the weather began to warm up, the honey that had been long subjected to a zero temperature for six weeks granulated; but the same honey that was kept in a warm room remained liquid.

These experiments, repeated at other times with the same result, go to show that cold is more conducive to granulation than a warm atmosphere, and that a *variable* temperature is far more potent than either.

Comb honey, unless it is very well ripen-

ed, should not be put in a cold room except temporarily, just before placing it on the table. In a zero cold or even a freezing cold comb honey cannot be handled without danger of breakage and leakage. Our comb honey, tons and tons of it, is always stored in a temperature of between 75 and 80, kept warm by means of steam heat or with a gas-stove when steam is not available. We would not, for a good many dollars, allow the temperature of the comb honey in our storage-room to drop to a freezing temperature for more than a short time.

Comb or extracted honey put in an ordinary ice-box or refrigerator for a few hours before eating is always improved; but at all other times it should be kept away from a cold atmosphere—particularly one that is changeable.

A Case of Chilled Brood in October

A BEEKEEPER in this county, some twelve miles from us, and eight miles from our nearest bees, came to our office one day, and said that something was awfully wrong among his bees. Most of them had carried young dead brood—lots of it—out in front of the entrances. The brood was white—that is to say, not discolored, nor anything like foul brood. He wished us to drive down and see what it was.

Knowing he had foul brood a year or so ago, we suspected this had something to do with it. We drove down in our machine, and examination showed quite a lot of young brood in the imago state in front of some of the entrances, that had been hauled out of the cells by the bees. Apparently the brood advanced to the stage just before the wings were formed, and then died. We went through several of his hives, and found that in every case where white dead brood was in front of the entrances the colony was too weak to keep the brood-nest warm. In at least four cases the colony had been reduced by American foul brood, and in several others the owner had put on upper stories of wet extracting-combs which he said he placed there temporarily for the bees to clean up. Shortly after this came a cold spell with a light freeze. This lasted for several days.

Colonies having brood-nests twice their normal size, or colonies reduced by American foul brood, had evidently contracted their clusters so that some of the sealed brood, at least, had chilled and died. This the bees removed, with results as stated.

We told our friend that he must get busy and clean up his American foul brood, or he would have something worse on his

hands than chilled brood. We noticed he had some old hives and some old combs under a shed. The covers did not fit very tightly, and robbers were smelling around. Most of the hives were old and home-made, with gaping cracks. We promised to send one of our best men down to help our friend out, because we cannot afford to have this condition of things even eight miles from our nearest outyard.

A word of caution should be entered right here, either to unite colonies that are not very strong, or contract their brood-nests. Too much hive capacity is bad. When the bees can hardly fill one story, it is folly to put on one or more stories of wet combs, and leave them there after a cold spell of weather comes on. There is nothing serious about a little dead brood; but all good healthy brood at this time of the year should be allowed to hatch. Every young bee is worth a dozen old bees for wintering.

Dr. Phillips' New Book, "Beekeeping"

Of the making of books there is no end, the wise man said. One would almost think there was no room for a new bee-book; but in Dr. Phillips' work, a preliminary notice of which appeared on page 739, Sept. 15, we have something new and unique. It covers a field only partly covered by others. How does it differ from other standard works on bees?

One would naturally suppose that its author, a scientific man—a trained entomologist, and one who is constantly associated with some of the best scientists of the Government—would turn out a book that would be so technically scientific that it would be beyond the reach of the average beekeeper. This is not the case. While it is scientific, it is couched in such language and style that the average reader can easily understand it. But when we say it is scientific, we might, without further qualification, convey the impression that it is not also practical. As a matter of fact, the book is intensely so, because Dr. Phillips has traveled all over the United States, mingling with the best beemen in the country, and he has had, during several years back, one of the best beekeepers in the United States, Mr. George F. Demuth, as his first assistant.

Mr. Demuth, by the way, is a man who has been making good with his bees year after year; and not only that, he has been operating his yards at long range, and still makes them pay. It is that man who has been the constant associate of Dr. Phillips,

and who went over the proofs carefully before the book was made public.

As if that were not enough, the author went still further and placed himself in touch with Dr. C. C. Miller, of Marengo, Ill. With manuscript in hand he read paragraph after paragraph to this modern Gamaliel. Dr. Miller, as those who know him best, is a severe critic, and anything that might not be perfectly orthodox so far as comb honey and swarming are concerned, would be caught by Dr. Miller. In the main he approved everything that the other doctor said, offering only here and there an occasional correction.

This work is distinct from any other on bees in that it does not follow in the wake of other writers. It deals with basic principles in such a way that the reader will better understand why this manipulation will work and why that will not.

For example, Dr. Phillips has undertaken the difficult task of giving the main cause of swarming. At first we were inclined to think he might have missed his mark; but the more we have studied his reasons the more we have come to the conclusion that he is probably right. But of this we shall have something more to say at another time.

In the matter of comb-honey production he has followed Mr. G. F. Demuth and Dr. Miller very closely. On the subject of wintering he sets forth some new principles—new, did we say? Well, not quite that either. He has discussed the subject from the standpoint of the causes that lead to failure and the elements that lead to success. He and his assistants in the Bureau of Entomology have made some new and important discoveries on the subject of wintering, some of which have been given in these columns. See page 789, 1914, and again on page 49 of this year. In the light of these discoveries he has set forth some principles that we verily believe will help clear up the subject of wintering, explaining why bees die sometimes and not others, in a way that has not been done before.

We hope, in a later issue, to give some extracts from this work; and while we may not agree with all that its author says, his is a book that the man who keeps bees for the bread and butter he can get out of them cannot afford not to read.

The price of the work is \$2.00, and it may be had from this office. It contains nearly 600 pages, well illustrated with pen-drawings that bring out all the details that it is possible to show. It will be clubbed with our own work, *The A B C and X Y Z of Bee Culture*, for \$3.00, or with *GLEANINGS* for one year for \$2.50.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

"HONEY is not apt to be used as much in extremely hot weather," p. 786. Is not that chiefly because honey is a heat-forming food, and so, like fats, is craved less in hot weather?"

GRACE ALLEN, p. 791, speaks of a meet of seven beekeepers, and says it was a good meeting. Even in a meeting of a hundred, it's the few of the right sort that make it good. One of the best beekeepers' meetings I ever attended was last labor day, with an assembly of three!

J. E. CRANE, I'm much interested in seeing that you replace old or inferior queens with virgins or queen-cells, p. 748. Now the thing I'm anxious to know is how many of these swarm out. I have an assistant who nearly has a fit every time I talk of putting a virgin or a cell in a full colony—says they'll swarm and go off.

J. L. BYER, p. 794, you express surprise that so good authorities have not heard the queens calling except on comb. If you call Editor Root and myself authorities, we both agree that a queen often pipes outside a hive, only he thinks the virgin says the same thing outside the cell that she said in it, and I don't. [See answer to another Straw on this question.—Ed.]

WHILE it is true that bees nearly always work on the same kind of flower on the same trip, and, indeed, in many cases throughout their whole lives, yet I have seen (I think never more than twice) a bee going back and forth to flowers not related. I don't know why—possibly because forage was so scarce that she was glad to visit any and every flower she could find. [It is the exception that proves the rule.—Ed.]

"THE Mineral Constituents of Honey," p. 797, is worthy of widest publication. I doubt if one beekeeper in a hundred realizes the importance of minerals in honey. Take iron alone. For years physicians have been always seeking for some better form in which to administer it, yet here it is in the best form in the most delightful vehicle, and yet for the most part ignored. I believe I'm a stronger man for the mineral elements I get in honey. And as a rule bees fed on honey have more vigor than those fed on sugar, since sugar is utterly lacking in the important mineral constituents.

MR. EDITOR, you ask, p. 790, "Is it not probable that the piping is made by a

hatched queen, and the quahking by another one in a cell as a challenge?" Certainly; only it is believed that the challenge is given by the one that pipes. You may be interested in seeing this matter discussed by the Baron of Berlepsch in *American Bee Journal* for 1861, p. 201. He found that the mature young queen (even if only one in a hive) always quahks for a time in her cell, before she emerges and pipes. He gives some very interesting observations, and says: "From these observations it is evident that young queens teet [pipe] and quahk from sheer jealousy; and that every queen, before emerging, quahks for a time, to assure herself that no rival is at large in the hive. Not till after her reiterated calls have remained unanswered does she feel herself safe, and release herself by severing the cap of the cell." You then ask, in substance, whether quahking is not the same as piping, only that the one that quahks is in the cell. Most emphatically, no. Whatever difference there may be from imprisonment in cell, there is one distinct difference that cannot be accounted for in that way—a difference that it doesn't need a musician to detect, as J. L. Byer seems to think. In piping, the first tone is long drawn out, several times as long as the last, each tone from first to last becoming shorter and shorter. In quahking the tones are all short and all of the same length. If a queen should be shut in a cell and should pipe, the first note would still be several times as long as the last, would it not? And in that respect it's utterly different from quahking. [We fail to see yet why piping and quahking cannot be made by the same organs and in the same way. While the notes are more prolonged in one case than in the other, is there any reason for it except that the waxen cells are nearly air-tight? and, moreover, bear in mind this: The noise, whatever it is, is made by the wings. We have seen queens pipe in queen-cages in our office. The wings make a tremulous motion, very plain to be seen. When the young queen is in the cell she probably does not have room enough to vibrate her wings as freely as she does when outside. She does the best she can; but her efforts in her narrow quarters of necessity result in a different sound. If you ever saw a queen pipe (and every queen-breeder has seen them do it hundreds of times) you will have noticed the vibratory movement of the wings close to the thorax.—Ed.]

J. E. Crane

SIFTINGS

Middlebury, Vt.

On page 651, Aug. 15, the crop in Ontario is given as fifty-five pounds per colony. Is this comb or extracted honey?

A bunch of sweet-clover blossoms, white and yellow mixed, makes a beautiful bouquet for the dining-room table.

The editor says, page 657, Aug. 15, "We should like to know what you mean by breeding from the best." Have we at this time any well-considered standards of excellence for our bees?

Dr. Miller, page 657, Aug. 15, says the *British Bee Journal* copies a clipping which says that one firm in that country uses 40 tons of honey a month in the manufacture of a cough mixture, and comments, "Some honey." I should say, "Some story."

On page 481, June 15, Dr. Miller says, "If all 'we men' had voted with me in the last forty years there wouldn't be a saloon in the land," and he is right; but that is not all. There wouldn't be one red-faced, unsteady-gaited man by newspaper courtesy called "drunks" where there are ten now.

Dr. Miller inquires, page 569, if we can steam a whole box of sections at once with a tea-kettle. Well, no—not unless you have a very strong jet of steam. We took a bundle that we could hold in the hand, allowing the steam to pass through the corners. It takes a little time, but does a good job.

The sum of \$25,000 paid out in one year for advertising honey by the A. I. Root Co. This seems like casting a good deal of bread on the water, expecting it to return after many days. I shall be greatly mistaken if the rank and file of beekeepers don't get some of that bread as well as the A. I. Root Co., when it returns.

I enjoyed reading Mr. O. O. Poppleton's experience with the Long-idea hive. I confess I was somewhat prejudiced against such a hive until I came in contact with it in his yard. The ease with which it can be opened and examined at any time, even when bees are storing surplus, will commend it to almost any one, especially in the South.

An article by John W. Love, page 668, Aug. 15, on the factor of cleanliness in honey distribution is of much interest. He says, "Comb honey put up in a dust-proof carton suggests delicacy and sanitation more than that displayed in a glass showcase." It is many years since we began to use cartons here in the East, and Mr. Burnett, of Chicago, informs us that they are coming into use in the West.

Looking over a yard yesterday for foul brood, I discovered one I had been into where robbing had begun. I tried to drive away the robbers with smoke, but the more I smoked the thicker they came. I piled grass and weeds about the entrance, but still they came. Then I placed an empty hive in front of the one they were trying to rob. In a moment they left the latter and rushed into the empty hive that contained some dry combs, and more surprised bees I never saw. The ruse was an entire success.

Several articles in the Aug. 15th *GLEANINGS* on aster honey show the widespread interest in this source of winter stores. The objections to it appear to be that it is thin, and bees winter badly on it. Now, I have my doubts as to whether it is any thinner when gathered than other honey or nectar; but it is gathered late, often when the weather is cool, and the bees are, for this reason, unable to reduce such nectar to a thickness or ripeness in the North as to make it a good winter food. Where such is the case I believe it would often be advisable to reduce the size of the brood-chamber to increase the temperature so it could be ripened.

That extract from the *Rural New-Yorker*, page 567, July 15, is well worth more than a year's subscription for *GLEANINGS*. I wanted to put in a half-acre, but thought I must first plow the ground—not necessary. And, again, I have wondered how it could be best brought in in pastures. I thought, of course, the first thing would be to plow the old rough pasture—a very difficult job; but from this I learn I can just disk the surface, roll, and sow the seed. It has seemed as though the use of sweet clover for pasture might be more helpful to beekeepers than that sown for hay, as it will be quite apt to get the start of stock and throw out a good deal of bloom the latter part of summer.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

Dr. Miller tells us, page 747, Sept. 15, what points he would breed for under various conditions, but omitted saying anything about disease-resisting qualities. Is that not one of the most important points in this day of disease?

Mr. Frank B. Gunther, of this city, has recently sold his apiary and retired from the bee business. Mr. Gunther has been a beekeeper in this locality for many years, and is one of the old timers. Failing health has caused his retirement.

Mr. W. T. Cary says, page 770, Sept. 15, "Use two queen-excluders instead of one, with a bee-space between them," as a modification of the Alexander plan for keeping queens apart. I am carrying several queens over others, separated only by screen wire, which, to my notion, is the best plan yet introduced.

On page 695 I read this headline: "Drone-laying Queen Brood Sometimes a Stinking Mess." Correct! I had some experience in that line last season and this. Last season I was very much alarmed for fear of "black brood," but it proved to be only dead brood dried down in the cells, and otherwise greatly resembling black brood. A change of queens soon corrected the matter.

There is a beekeeper in this locality who claims to have cured American foul brood in an apiary that was badly affected, without destroying any combs above the excluders, the bees being allowed the free use of the honey. He contends that the honey above the excluders is not diseased; and to my notion he has proved the fact. But it must be remembered that the excluders are not to be removed at any time of the year. Shaking (or any other system used) can be carried on without permanently removing the excluders.

Mr. Crane says, page 658, Aug. 15, "Do we sing as we work? It is interesting to note that the birds sing the most when they work the hardest during the nest-building and the rearing of their young." Well, most of the singing takes place during the nest-building, Bro. Crane. When the little mouths begin to open for food there is a

change in the atmosphere, so to speak, and business takes the place of song. I am "some wise" on this line from my own experience.

On page 698, Sept. 1, the editor says: "Every time the granulated article is reliquefied some of the flavor is lost." That depends on how it is reliquefied. If the cans are set in the hot sun with the caps left on, the honey will reliquefy without any injury to the flavor. This season I placed a quantity of granulated orange honey in a local warehouse on an upper floor next to the roof. The heat during the summer became intense at times, causing the honey to reliquefy perfectly, yet I do not think any one could detect the slightest injury to the flavor. In my opinion intense artificial heat is the chief cause of the loss of flavor.

In dividing colonies for increase, the old queen with the old bees should be left on the old stand, and the young bees and a good portion of the brood moved to a new stand. Many do not realize the importance of eliminating the old bees as much as possible before introducing the new queen. It is a good plan to remove a colony to a new place when introducing a queen and placing an empty hive on the old stand for a few days to catch the old bees, after which they may be returned to the original colony on the original position. This is not necessary where there are other hives near for the field force to find their way into.

Dr. Miller, page 631, Aug. 1, says he has had many cases of laying workers, but does not remember a single case in the spring. Well, as I have before said, that is the most natural time for them to occur with me, and I have seen very few after the season was advanced far enough for the production of plenty of drones. He asks also if I ever knew a case of laying workers and not a whole lot of 'em. Now he has me, and I believe the whole beekeeping fraternity. I never saw a bee in my life that I could point out as a "laying worker." If Dr. Miller has, he is an exception and has enjoyed a rare sight. Following the instinct of the bee it is more natural to think of a colony tolerating only one laying bee to the hive. And, 'way down in the bottom of my heart, I don't believe that any one knows.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas.

A TRIP TO CALIFORNIA.

If time permits I will take a trip to California this fall. The primary object of the trip will be to visit some of the leading California beekeepers and to study beekeeping conditions as they exist in that state. It is to be a mission similar to that on which the Texas A. and M. College sent me to Colorado a number of years ago. At that time I was connected with that institution as apiarist and foul-brood inspector. During the last few years my connection with the state department of agriculture has been that of apicultural expert. I have always made it a point to gather all the information possible on beekeeping subjects. My main object on the Colorado visit was to look into the foul-brood situation there and the inspection work. My thirty days' sojourn in that state, and the visits to the numerous beekeepers, proved extremely profitable. I am anticipating the same experience in my California trip.

Some of the first information that would be appreciated by me would be suggestions as to the best routing of a trip in order to reach the most of the interesting places that I ought to try to arrange to see. Of course, it will be impossible to make all the important points nor to visit all the beekeepers whom I ought to see; but with such information as I may be able to get from those who will be kind enough to write me, I shall be better enabled to outline an itinerary that will be the most profitable to me. The editor can start the ball rolling, from the fact that he has recently been there. Who else will write me? I shall also be glad to hear from some of my California friends.

THE SEASON AT PRESENT IN TEXAS.

Rain, rain, rain! There has been hardly a day for the last month or more when we did not have one or more showers of rain. While these were extremely welcome at the beginning, their continuance and the resultant bad roads and delayed work of various kinds have been deplored by many. I had wished most anxiously for these fall rains to set in, long before they came. It had been very drouthy for a good many weeks, and our bees were doing absolutely nothing as a result of the cotton stopping growing long before the usual time. A rain in July would have meant a continuation of our

summer honey yield from that source without a stop; but the extremely dry weather put an end absolutely to the honey-flow from the cotton. From similar experiences I knew that only some light rains would mean that the cotton would put out a fresh growth, and our honey yield from that source be increased. Although this has come a little later than usual our bees will still get a nice lot of honey. They are already busy on the cotton, and also on broomweed as well, and some of the wild fall flowers.

These rains seem to have been quite general over the state. While the Southwest Texas section will not reap any surplus honey I feel that the rains have been beneficial in stimulating some of the fall honey-yielding plants to permit the bees there to store up at least some winter stores. The broomweed is the chief of these fall yielders there. Although the honey is rather strong, and yellow in color, it is excellent for winter stores. The beekeepers in that part of the state have had a short crop, except in a few favored localities, and have had to feed their bees in some instances.

Throughout the central and northern part of the state, especially throughout the cotton-growing belt, there has been less complaint. In fact, many of the beekeepers with whom I have had occasion to converse during the last few weeks have admitted that they were getting a better crop than they anticipated after considering the unfavorable spring conditions.

As we use a great deal of extracted honey for packing our bulk comb honey we buy large quantities from other beekeepers every year. Thus far we have already bought over 50,000 pounds this year. Although indications at first were that there would be a shortage of extracted honey, and we were beginning to arrange for procuring our necessary supply from other sources, we have been receiving more offers of extracted honey than we anticipated. Indeed, lately the offerings have been beyond our needs at times. At the present time we have nearly a dozen letters offering extracted honey.

I have mentioned this because it tends to show that there was a good deal of honey produced in Texas in spite of the reports prevalent to the effect that there has been an almost entire failure in the Lone Star State. Our own crop will not be far behind our last year's yield, if not just as good.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

COLORS AND QUEENS.

"Do bees dislike black? Will they try to sting an animal that is black any sooner than they will one that is gray, brown, red, or white? I am told that bees have this special antipathy."

In my younger years in apiculture I accepted the idea as the truth. One day four of us met at one of the apiaries, I wearing a black felt hat, the other three wearing straw hats. It was not long before Doolittle was the target for apparently all of the cross bees in the apiary, the bees getting on that black hat and singing and stinging very much as they will in one's hair. Of course the trouble was in the color.

A few weeks later we met in another apiary, I wearing a white felt hat, and the others had hats of various shades, but none black. To my surprise, I was again the target for the cross bees, as the hat I wore seemed to displease the bees much more than the hats of other colors. They sang and stung away at that hat the same as they had done when I wore the black one. Again we met at my own apiary; and as this was a very warm day we all wore straw hats of about the same color. To my surprise, I was again the target for nearly all the cross bees we happened to stir up—not that the bees attacked my hat more, but they seemed to want to sting Doolittle more than any of the other three.

Then I concluded that their dislike was for my person. And I have found this to be so in the majority of cases wherever I have visited with beekeepers at different apiaries. I have often felt almost ashamed of myself when being obliged to hide my head in a bush or call for a veil when others had no trouble. But of this I am certain: Bees have a great antipathy toward any clothing that is fuzzy or of a hairy nature, and such should be avoided when work is to be done in the apiary.

"Is the practice of cutting out queen-cells at the beginning of the swarming season, to prevent swarming, a good one where one works for section honey?"

Quite a few of our practical apiarists have given that plan as a good one; but from years of experimenting along that line I cannot help thinking that much honey is lost in the attempt to stop prime swarming by destroying queen-cells. And I also think that the attempt to stop after-swarming by the same practice often in-

creases the number of after-swarms. Especially is this true when the cells are cut before all the unsealed larvæ are too old to be coaxed into something that will temporarily answer for a queen. Under the swarming impulse, bees do not take kindly to being allowed just one queen-cell; therefore, when they have any larvæ which can possibly be transformed into something which will take the place of a queen they will do this, and so issue as a "second swarm" with the queen emerging from the cell we have chosen for them, thus leaving the parent colony with but a poor apology for a mother. It is better to wait eight days after the issuing of the prime swarm, and then at night listen at the side of the hive, with the ear pressed against it, for the piping of the first young queen that has emerged. When the young queen is twenty-four hours out she will tell you herself that "there will be a hot time in the old town" tomorrow by the fuss she is making inside during the gathering darkness. In the morning you can shake the bees off every comb in the hive, so that you can see every queen-cell, and miss none; and when all are cut off you are sure of no after-swarm.

"Would not the following be a good way to requeen each colony every year and prevent all increase? Allow the prime swarm to come out naturally. Have all wintered-over queens' wings clipped. When the swarm is in the air, cage the clipped queen and go through the hive, cutting off all queen-cells. Lay the caged queen at the entrance, and two or three of the best cells around the cage containing the queen. When the swarm returns, place an open-mouthed box over the caged queen and cells, thus allowing the bees to cluster over and about them. Eventually the old queen is to be killed, and the first queen emerging from the cells at the door reigns in the hive for another year."

The question would be whether doorstep foundlings would be as good as lawful ones nursed and brought up in the genial warmth surrounding them in the old homestead. Even if a small bunch of bees stays there faithfully, would not the temperature inside the bunch get low on a cool rainy night? Then, what would there be to hinder the bees inside the hive, with mother and embryo sisters gone, starting more queen-cells from the brood remaining in the hive, which, much of it, would be of right age to change to queens?

GENERAL CORRESPONDENCE

SOME REMINISCENCES OF A LIFE AS A BEEKEEPER AND SUPPLY-DEALER

BY WALTER S. POWDER

In my boyhood days, while with my parents on a fruit-farm at the edge of Cincinnati, I was much given to nature studies. The honeybee appealed to me as the most fascinating study in all the world, and it became my irresistible hobby, much against advice from those who were near to me. I secured all the literature available at that time, had valuable instructions from the late Charles F. Muth, kept my little apiary attractive with the lawn-mower and by building rustic chairs under the shade-trees, and then I had but one goal in view—I longed for at least one hundred colonies. I even thought that if I could secure the larger apiary I would be so contented that I would never ask for anything further.

I reached the goal; but while I secured much pleasure in reaching it I still found other wishes developing. I now began to wish that I could rear queen bees and advertise them in the bee journals. I had secured a crop of honey so large, filling tanks and barrels, that my father had some fears that the honey-house would yield to the weight. My honey-house was the upper floor of our shop, strongly built; but I remember his placing braces under the floor. My father found a demand for every pound of honey that I produced; and as I was determined to say that I was never out of honey I had occasion to purchase several barrels of it from New York and from Michigan, honey in those days being shipped in barrels and kegs instead of tin cans. This proved profitable, and here is a hint for beekeepers of today.

My entire apiary was devoted exclusively to producing extracted honey, using two-story Langstroth hives with ten Langstroth frames to each story, and a queen-excluding honey-board. This controlled the swarming problems; for at the beginning of the flow I would place the queen and two or three frames of brood in the lower story, filling the story with empty frames, and placing the rest of the brood in the upper story over the excluder. I often found it necessary to build many colonies three stories high.

It had been one of my pleasures to provide an ample supply of combs, all built

from full sheets and mostly wired. At the beginning I had quite a few crooked combs, and a few that had large patches of drone comb. I gradually disposed of them by cutting out drone comb and cutting up some of my best combs with which to patch or replace the drone comb. I also managed to have all of my combs built to the bottom-bars of frames. To accomplish this I cut off the lower edge and replaced with a strip of comb to fit, and returned such combs always in the upper story.

I also learned to secure absolutely perfect combs without wiring. The idea would be quite practical today; but it seems that the time is not ripe for it. I would use full sheets of medium-brood foundation, cutting off half an inch from the end of each sheet. The object is, not to allow the sheet to touch the end-bars till it can have time to hang plumb. These frames are now to be inserted in brood-chambers, a few at a time, and always between combs of brood so that an equal force of bees will work on both sides of the frame at the same time. After one season in the brood-chamber they can safely be used in upper stories for extracting.

My experience in producing comb honey was not entirely satisfactory; at least I realized that I could secure more dollars and cents on the plan of extracting. In those days a section about four by five, used without separators, was quite popular, and I am not sure that it was not a mistake to discard it, for the smaller section with separators and small clusters does not bring as good results. We know that anything that divides the cluster is against comb-building. For those who ship comb honey, separators seem to be a necessity.

I produced one lot of strictly fancy comb honey, but I had my sections, supers, and separators made to order, using a section open top and bottom, and also open at corners—a sort of compromise between the plain and the standard section, and it could be used with or without separators. This was back in the '80's, and the sections were illustrated and described in GLEANINGS. The article brought me so many inquiries that I began to think I had the world by the tail; but my hold soon relaxed, for I

was not prepared to offer the goods. I used separators made of coarse wire cloth, and sections were clamped with thumb-screws.

In using some of this honey in an exhibit I recall one man remarking that bees had never seen that honey! I tried to explain that machine honey was out of the question; but as he walked away he muttered, "Well, I don't know. I have just found out that I have been eating manufactured eggs all winter."

Speaking about producing comb honey, I think now that if I were so fortunate as to be back in the business I would produce both extracted and chunk honey. There is an increased demand for chunk honey, and it enables the producer to secure the price of comb honey for a whole lot of his extracted honey. I think I would produce some comb honey in shallow extracting-frames and cut it out as fast as I secured orders. One must not prepare a lot ahead, for it is not desirable to allow granulation. I would use a six-pound pail with three pounds of comb and three pounds of extracted. In fact, when I did have goods to sell I used this method of putting up honey, and found a rapidly increasing demand. The method came to me by accident in taking care of comb honey that arrived here in broken condition.

Speaking about establishing myself back in the '80's as a queen-breeder, the more I thought of it the more I became enthused, for I felt that my surroundings were favorable, and I began to dream of pleased customers and taking armloads of cages to the postoffice! I also realized that much expense would be attached in requeening my yard, and that much material would be required for mating-boxes. I would not consider anything but the highest standards in every detail. I formulated my plans, and began that winter in making all arrangements, completing my library, making mating-boxes, etc. About one year was consumed in requeening my yard to the standard that I required.

My mating-boxes were my own idea, and I still think well of them in spite of strides in improvements. I ordered ten-frame hive-bodies with tops and bottoms and grooves cut in ends for three thin division-boards which made four compartments with an entrance at each end and one at each side. The point was that they would co-operate on heat, and that by using the standard frame I could unite at the close of the season with no loss of bees or brood. A detachable number-disc hung on each compartment, and one on each hive gave me

opportunities for an accurate book-record of every queen in my yard.

In those days much was said about controlling the mating of queens, and for a time I thought I had at least partly solved the problem. We knew that queens usually take their flight in the early afternoon, at such times as young bees are taking play-spells. I knew that by feeding my nuclei a small amount of syrup in the forenoon the queen would take her flight, and at such times very few drones were in the air; but by feeding my best colonies I could also force the drones to fly at the same time. I still think that something might yet be accomplished by further experimenting in this line.

My hand-hold slipped again! In queen-rearing I met with quite a few failures, and found it necessary to refer to my books frequently. With more experience I was more successful; and yet it seems to me that I followed old plans, and I do not know to this day why some ideas were failures and again successful after pursuing the same methods. Perhaps my enthusiasm had a bad effect at the beginning. Our text-books are fine, but there is one thing that has always given me much concern. It is the ideas expressed about fertile workers and drone-laying queens.

I cannot induce myself to believe that ever a seed in vegetation germinated without pollenization or that ever an egg laid by an insect developed life without fertilization. I should like to see modern science go deeper on this subject. Modern science seems to go deeper on subjects where more value is at stake, such as mining, medicine, etc., but I find what I think is a parallel case on my subject pertaining to the eel. Aristotle taught that the eel was without sex, and that they were produced spontaneously from the earth, and even Pliny agreed with him. It was not till 1877 that an Italian naturalist identified a female eel, and showed that they lay millions of eggs, always in brackish waters. As a matter of commerce the bee is far ahead of the eel, although eels are considered a fine article of food by some people.

Excuse me, for they remind me of a snake; but I presume it is all a matter of taste. I learn that snails are considered a delicate dish in Paris! This reminds me of a story about a foreigner visiting this country. His friend wished to secure for him a fine café dinner, and they sat down to celery and bouillon; and then after clearing the table the waiter brought in a piping-hot lobster with the accessories. The foreigner pushed back his chair and remark-

Heartsease, *Polygnum persicaria*. Photo by J. M. Buchanan, Franklin, Tenn.

Boneset, *Eupatorium perfoliatum*. Photo by J. M. Buchanan, Franklin, Tenn.

ed, "I ate your grass, I drank your slop, but I'll be dommed if I ate you bug!" I find that I am getting off my subject.

When I had secured queens ready for the market I was confronted with the problem of advertising—a subject which I have since found very interesting and deep. I tried small spaces in bee journals, and expected a deluge of orders; but in this I was again disappointed. I was unknown; and if it had not been for the fact that I secured some advertising space in exchange for bee notes in a farm paper I would have come out of the little end of the horn. At a time when I was a little discouraged, the late Charles F. Muth visited at our home. He looked over my outfit; and before he left he said, "Walter, for the present I can use all the queen bees that you can produce." His kind and gratifying words can never be forgotten.

Well, I found myself so fascinated with the bee business that I had promised myself that, if I were rewarded with a first-class apiary, and established in the queen-rearing business, I would never ask for anything further, especially if these things were gained by the sweat of my own brow. Now, things were different again. I began to have a longing to go into the supply business.

I spent one winter with the A. I. Root Co., and the more I learned about it the more it seemed to fascinate me; and the very odor of pine lumber and beeswax seemingly intoxicated me. I had met many beekeepers, and I thought them as a class the best people on earth. I have never changed my mind on this point. My opportunities at home were good, but I was worried about getting in the supply business. I had seen good men fail after starting with considerable means while others prospered; but I felt that I could succeed if I only had the opportunities, but there seemed to be no openings. However, the darkest hour is just before day, and I had even looked over the map deciding that, if I had my choice, I would locate in Indianapolis. I had occasion to visit friends in Indianapolis, and just naturally hunted up the local bee-supply dealer, Mr. Frank L. Dougherty.

After cordially shaking hands in the attitude of the bee fraternity he confided to me that he had been promoted to more extensive interests, and that his supply business was for sale. This brought me to a fever again, and I learned that another man was negotiating for the business—a man with much more means than I could

Aster, *Aster multiflorus*. Photo by J. M. Buchanan, Franklin, Tenn.

control. I returned with a heavy heart, exchanged a few letters with Mr. Dougherty, resulting in his giving me the preference—a kindness that will be lasting in my memory. I conducted it for twenty-six

years with some hardships, some hard work, but, after all, a quarter of a century of real pleasure. And I still think that the beekeepers are the best people on earth.

Indianapolis, Ind.

THE FALL FLOW

BY J. M. BUCHANAN

The late summer and fall flow is an important factor in the next season's honey crop; for strong colonies at the beginning of the spring flow are dependent on successful wintering, which, to a great extent, is insured by having the hives full of good stores and young bees at the beginning of cold weather.

If there is no fall flow to induce late brood-rearing, the colony goes into winter with old bees which have not sufficient vitality to survive the cold and confinement of winter; and if stimulative feeding ever pays, it is at such a time as this, for too much importance can hardly be placed on the matter of late rearing of brood.

There is quite a variety of plants throughout the central states which furnish nectar and pollen during the late summer and autumn, and a short description of some of the most important is here given.

Polygonum persicaria, heartsease, smartweed; a prolific nectar-bearer in low lands and moist soils. The honey is of good flavor, and light amber in color; blooms in August and September.

Eupatorium perfoliatum, boneset. On the high lands of the central states this plant furnishes a good crop of surplus honey of fair quality, light amber in color, and of rather high flavor. It grows 2 to 4 feet high and has white flowers in broad flat heads, in August.

Solidago, goldenrod. There are more than 75 species of goldenrod found in the United States. However, not all of these are of value as honey-plants. There are several good ones which are widely distributed, and which produce a fine quality of honey, mostly of a golden color. They bloom during September and October. Two species are shown in the illustration.

Crab spider caught in the act of killing a bee.

Aster, aster. Several species or varieties are of value as honey-plants, some producing much better honey than others. Aster honey is very quick to granulate, and is rather strong in flavor. It is not usually considered very good for winter stores, especially in the North, where the bees are confined for a long period. There is generally a sour smell about the apiary when the bees are at work on aster. The bloom

begins in September, and continues until after frost.

Other late-flowering honey-plants which might be mentioned are buckwheat; alsike and sweet clover; cotton, cowpeas, wild sunflowers. The common ragweed, *Ambrosia artemisiæfolia*, is one of the most prolific pollen-bearing plants among the late bloomers, although it furnishes no nectar.

Franklin, Tenn.

THE TRAGIC SIDE OF BEE LIFE

BY WILLIAM BEUCUS

When we turn to the daily life of the bee and see how its fructifying mission is beneficent, how it is called to the delicate fragrant blooms which crown the vegetable kingdom, and which are a synonym of loveliness, we are quite overcome, and exclaim at the transcendent beauty of it all; but when we find lurking at the portal of the lily of the field a monster whose only mission is to seize and destroy the bee, to hold it in a vise-like grip while it calmly punctures the living tissues of its victim, the face of nature loses its charm, and its ugliness is unveiled.

The labor of the bee is kindly and constructive; and yet it must, at every trip,

face the pirates of the earth and the air whose labor is cruel and destructive. One of these monsters is shown in the photo. It is a white spider which lurks on white blossoms. Its duplicate in form, though colored yellow, lurks on yellow blossoms. This spider spins no web; but with arms outspread, it patiently awaits the coming of its only victim, the honeybee. It does not spring, but waits until the head of the bee is in exactly the right position between the outstretched arms, and then, with a swift movement, it seizes the bee in a powerful embrace and bites into the neck from the upper side, as shown. The bee has no chance to defend itself, and falls an easy

victim. The particular spider pictured was caught in the corolla of the wild white lily. It was rudely driven out, clinging tenaciously to its prey, on to a green leaf, carried into the house, the leaf pinned to a box, and the photo taken.

Several years ago one of these spiders was compelled to release reluctantly its victim; and it was then carried to a populous colony and dropped at the entrance among the bees. They seemed to recognize their enemy, and drew away. After considerable irritation, one bee, more valiant or indiscreet than the rest, attacked the spider viciously. Instead of showing fear, the spider seized the bee in a strong grip and bit it on the under side of the thorax. The bee was thus in a position where it could use its sting. But it wilted as though paralyzed by a poison.

This observation may prove interesting to those entomologists who assert that the spider secretes no poison. I then caught a worker, and, holding the spider securely, held the point of the bee's abdomen on to the spider that the sting might be made effective in retaliation. But the sting seemed to be unable to penetrate the skin of the spider, although many efforts were made. It seems, then, that, though the spider takes the precaution to seize the bee in the safest way, it would not be in danger, even if the bee were seized wrongly.

Spiders which kill honeybees. 1, black swallow-tail butterfly (*Papilio asterias*), killed by crab-spider *Misumena vatia*, 2. 3, dragonfly (*Celithemis sp.*), captured by *M. vatia*, 4. Photographed by John H. Lovell.

To gratify my own feelings this spider was despatched, as was also the one shown in the photograph.

Cadott, Wis.

[Chas. Hecht, in the Oct. 15th issue for 1907, describes this same spider, and an illustration is given showing the spider and its victim on a dandelion blossom. Mr. Lovell, in his article which follows, shows a spider which is, no doubt, the same one, killing butterflies.—Ed.]

FLOWER SPIDERS WHICH KILL HONEYBEES

BY JOHN H. LOVELL

In gathering nectar from flowers a honeybee would seem to be in no danger; yet often it meets with a tragic end. Here lying on the flat top of the flower-cluster of the hobble-bush is a dead bee. Lift it up and you may discover that the head is firmly grasped by the mandibles of a white spider, which, rather than release its prey,

permits itself to be dragged from its hiding-place. Except for a red stripe on each side of the abdomen, it is wholly white, so that it cannot be easily distinguished from the small flowers among which it lives.

It is one of the crab-spiders (*Thomisidae*), so called because, like a crab, they walk sidewise or backward more easily than

Dr. Neville's summer and winter repository for bees.

forward. These spiders lurk among flowers, usually in dense clusters of small flowers like the meadow-sweet, the sumac, the elderberry, and viburnums, and pounce upon the unsuspecting insect-visitors. The two commonest species are *Misumena vatia* (shown in the photograph), and *M. aleatoria*. They not only catch bees and flies, but also wasps and large butterflies and dragonflies, as the illustration shows. The poison is very virulent, or otherwise they would be carried away by such strong-winged insects. These spiders are common, and kill a good many honeybees.

On the 16th of July I noticed a bumblebee gathering pollen on a flower of the wild rose (*Rosa lucida*). My attention was for a moment diverted, but was again quickly recalled by the loud buzzing of the bee. A white spider had leaped upon its back and grasped it with its mandibles just behind the head. At first the bumblebee struggled violently, but gradually its efforts became more feeble and soon ceased. The spider now dragged it over the edge of the flower to the leaves beneath, there to dine at its leisure.

A COMBINED SUMMER AND WINTER SHED FOR CITY USE

BY DR. R. NEVILLE

The illustration shows my bee-house which I use both summer and winter here in town. In the summer the hives are 28 inches above the floor where they are placed during the winter. This means that, during the summer time, the entrances are at least four feet from the ground so that the bees are usually above the head by the time they are out of my lot.

The lower part of the shed is of concrete blocks, resting on a foundation wall four

inches high, through which openings are left for the winter entrances. The shed is 40 feet long and 4 feet wide outside measurements; 32 inches in the clear on the inside.

After the hives are placed down on the floor inside for winter, we secure boxes that have been used for shipping panes of glass; fill the three-inch space inside with dry straw, and place it over the top for a covering—finally putting on the boards used for

the summer stands. In this way we can winter strong three-frame nuclei without losing one, making sure, of course, that the combs contain plenty of stores.

A strip of rubberoid roofing-paper covers up the openings for the fronts of the hives in the summer time.

After 35 years of experience we have found this shed the most convenient ar-

range of anything we have ever tried for city beekeeping.

Walkerton, Ind.

[Dr. Neville is an old soldier who served three years in the Civil War, and who marched with Sherman to the sea. His bees are kept mainly for pleasure, but he produces some 500 to 1000 pounds of honey a season from his bees on his back lot.—ED.]

MAKING SURE OF SUPERSEDURE

BY F. A. HARRISON

The photograph shows both sides of a frame of brood which, according to my count, had twenty-eight queen-cells. This comb belongs to a new colony which swarmed May 17, 1915, and was placed in a new hive with full sheets of foundation. This is absolutely all the brood in this hive. Can you tell me why so many queen-cells are built by a new swarm?

The hospital at this station has eight colonies which are kept inside the walls of this institution. I have thought seriously of sending a photo to compete for a prize showing how bees can be kept when closely

surrounded by men at work. However, if our apiary increases as much next year as it has this I am afraid we shall have to move outside.

Fort Leavenworth, Kan.

[This was a rather unusual occurrence.

We assume that this was a prime swarm—that is, the first swarm—therefore that it contained the old queen. Probably this old queen began to fail soon after the swarm

Twenty-eight queen-cells built by the bees of a new swarm.

was hived. The fact that she had only a small patch of brood on each side of one comb a month afterward is pretty conclusive evidence that she had all but stopped laying. The bees decided to supersede her, and then "got busy" with what little brood they had.—ED.]

A PLANT THAT FORETELLS THE ALFALFA HONEY CROP

BY GEO. M. HUNTINGTON

I am sending two snapshots of wild buckwheat, *Eriogonum fasciculatum*, a very important honey-plant to the beekeepers of this valley wherever it is in the vicinity of their apiaries. It comes into bloom just before alfalfa, and is a good indicator of crop prospects for the season. Coming just before alfalfa it prepares the way for good results from the alfalfa. It starts the bees into the supers and provides the wax scales for comb-building. If there is a good flow

from the wild buckwheat the condition is sure to be such that alfalfa will also produce well.

Swarming is about over at the height of its bloom, and the earlier swarms have made progress during the buckwheat flow to where they will be storing surplus when alfalfa starts. Like the cultivation of buckwheat it is the best in the early part of the day, and in cool weather (not cold) it gives the best results. Two or three hot days at

Wild buckwheat is a forerunner of alfalfa in parts of California.

the finish will wind it up, and is just what the alfalfa needs to come on with a rush. The season of 1914 was like this, and the wax-workers were not "laid off" between the flows.

In 1915 the wild-buckwheat flow was

very short, as was also the first flow of alfalfa.

Wild-buckwheat honey is dark in color, but not as dark as its cultivated cousin. The flavor is also much milder.

Bishop, Cal.

GETTING READY FOR COLD WEATHER

BY D. C. ANDERSON

I have wintered bees for the last three winters as follows: I built a platform 4 ft. 6 in. by 9 ft., about eight inches from the ground. On this I placed ten hives, four fronting east, four west, and two south, and closed the entrances to about six inches in length by $\frac{3}{8}$ in depth. On the fronts of the hives over the alighting-board I put a 1 x 6-inch board flatwise.

The side-boards are two boards nailed with cleats one inch from the end, set on the outer edge of the board over the alighting-boards. One-inch boards the right length are tacked on the ends against the cleats, leaving the nailheads out far enough so they can be drawn out when you wish to take the case down.

The side-boards should be a few inches narrower at the north end to carry the water off. I pack with leaves, having plenty of them, tamping them tightly all about the hives. Sometimes I fill the supers with leaves, and sometimes put the covers on and pack the case full of leaves; then cover

with boards and roofing-felt. As the board over the alighting-boards projects somewhat I nail a narrow board on the front that keeps the storms from driving in the hives.

My bees have always wintered well in this case, never losing any excepting from starvation or loss of queen. Bees get a flight every month in the winter here; but we also have zero weather. It seldom lasts more than a few days.

I have also a tenement hive six feet long, spaced for four colonies with 12 to 14 Hoffman frames. The top is spaced for ten-frame supers. The divisions are of inch lumber, with a 5 x 5-inch hole in the center, over which is tacked excluder zinc on each side, so the queens cannot reach each other. The entrances are north, south, east, and west.

For wintering I tack newspaper on the sides and ends; nail a wide inch board over the paper, fill the supers with leaves, and finally cover to keep the storms out.

I have had this hive four years, and for three years it was the best honey-producer in my yard; but this last summer my bees got the swarming fever, and this hive will not give much surplus. The first winter I

tried to winter all four colonies; but the colony facing north disappeared. I do not know that it would have occurred again, but I never tried to winter any bees in that compartment afterward.

Boicourt, Kan.

SELF-TRIPPING OF ALFALFA

BY J. H. LOVELL

Alfalfa sometimes sets seed freely, even in the absence of insects suitable for tripping the flowers. The Bureau of Plant Industry has recently shown (1914) that the flowers often trip automatically. Alfalfa has explosive flowers—that is, when the keel is depressed the stamens and pistil fly forcibly upward with a snapping sound, and a little cloud of pollen is thrown into the air or against an insect. At Chinook, Montana, 33 out of 57 flowers marked on one plant became self-tripped and set 21 pods. On a second plant 36 flowers out of 64 tripped automatically and produced 16 pods. Self-tripping is influenced by temperature, humidity, and bright sunshine. A single alfalfa-plant was screened from insects for ten days or longer until it was in full bloom. The screen was then removed for 15 minutes on a very warm day. The flowers quickly began exploding with a snapping sound at times three or four being heard simultaneously. It was estimated that more than half the flowers were self-tripped before the screen was replaced. In the West, automatic self-tripping probably results in the production of as many pods as insect pollination. This observation is important, since it explains the production of a large crop of seed in the absence of insects.

THE ODOR OF GOLDENROD NECTAR.

While the bees are bringing in nectar from the goldenrod, the whole apiary is filled with a disagreeable sour smell which, on a calm evening, may sometimes be no-

ticed at a distance of a hundred feet. The odor of goldenrod nectar has been likened to that of decaying carrion, but this is a mistake. When such an odor is present it is usually caused by one or more stink-horn fungi. One autumn I noticed in my beeyard a strong carrion-like odor, and careful search soon revealed several of these fungi growing near an apple-tree. At least a dozen flies were busily feeding on the semi-liquid mass. Where there is decaying

The stink-horn fungus (*Phallus impudicus*) sometimes grows up in the apiary in the fall.

organic matter the stink-horn fungus frequently spring up in the fall. They exhale a fetid scent, and often mislead the beekeeper into the belief that this odor comes from the hives. The stem is hollow, and the cap-like top deliquesces into a sticky, syrupy mass which is very attractive to carrion-flies. They devour great numbers of the spores, which produce a kind of diarrhea, and pass through them unharmed.

The Tri-state Field Meet at Hamilton, Ill., Sept. 7 and 8.

ed. Certain fungi thus, like flowers, make use of insects to distribute their spores. The illustration shows two specimens of this fungus (*Phallus impudicus*).

Waldoboro, Maine.

[Every fall we receive a large number of letters from beginners who describe a pe-

culiar smell when the hives are opened. Is it not possible that the odor so frequently described as "sour" does come from the raw nectar of goldenrod, and that the odor resembling decaying animal matter is from the fungus described by our correspondent?—Ed.]

THE TRI-STATE FIELD MEET AT HAMILTON, ILL., SEPT. 7 AND 8

BY E. R. ROOT

This was one of the most enthusiastic meets I have ever attended. The day and place of meeting, about two miles out from Hamilton, were ideal. The bees were working heavily in the fields at the time; and, all together, the conditions could not have been better. Our hosts, the Dadants, and that means quite a family of them, including sons and sons-in-law and daughters and daughters-in-law, left nothing undone to make the occasion a success; and those who had the privilege of attending felt that they were most royally entertained.

The picture shows the original Dadant homestead where the late Charles Dadant and his son, Camille P. Dadant, began their beekeeping careers in the early '60's. At the right is the bee-yard consisting of those immense Dadant colonies in Dadant hives, Quinby size. Some of the old original hives were still in use. At the left is a portion of the Dadant foundation-factory and work-shop, where tons and tons of the

finest product are turned out. It is unnecessary for us to state that the Dadant foundation is known the world over. Every one was given an opportunity to go through the plant in groups of twenty-five and fifty at a time, piloted by one of the Dadants.

In this connection I cannot forbear making the observation that the firm of C. P. Dadant & Sons is organized very much like the A. I. Root Co. They are both strictly family affairs, made up of sons and daughters and sons-in-law and daughters-in-law. Each member of the concern is in charge of a department of his own. Mr. C. P. Dadant seems to be the presiding genius, and, as he said to us, he is "taking life easy," and letting the boys run the business. In that respect he is following the example of A. I. Root. Mr. M. G. Dadant and his oldest sister have direct charge of the *American Bee Journal*, which the Dadants purchased a few years ago of Mr. G. W. York. Messrs. L. C. and Henry Dadant and a son-

in-law are connected directly with the manufacturing end of the business, and that takes in the various out-yards and the production of honey as a business.

We hope to present the pictures of the members of this interesting family later to our readers.

Dr. E. F. Phillips and myself arrived in the forenoon. Already groups of beekeepers were in the yard. In one case Mr. L. C. Dadant had opened up one colony that had a plain case of dead *drone* brood—the very thing that was described in GLEANINGS for Sept. 1, page 695.

The beekeepers assembled here and there, opened up some of those big colonies, and discussed bees and methods of manipulation. At the noon hour the whole crowd, something over one hundred, sat down to a most bountiful repast. This part of the program was a great success, and was so pronounced by every one who had a chance to sample the Dadant hospitality.

After dinner the beekeepers were called together in convention by Frank C. Pellett, at which time we listened to some informal talks by Dr. E. F. Phillips; Mr. C. P. Dadant; Mr. A. L. Kildow, of Illinois, state bee inspector, and Mr. Frank Coverdale, the sweet-clover expert, of Iowa, well known all over the United States.

Mr. Coverdale, of course, was given the subject of sweet clover. He is not only an extensive beekeeper, but a successful farmer. He has done, perhaps, more than any other man in the United States to demonstrate the value of sweet clover, not only as

a forage plant for bees, but for cattle and hogs. He grows great quantities of the legume, and his success has been so great that it has attracted the attention of state experiment stations and the United States Department of Agriculture.

Mr. Coverdale had just sold a lot of cattle that he had raised, and these cattle brought \$1.00 per 100 lbs. above the general market. He explained that he secured this extra price because the cattle were so sleek. Sweet clover, he said, is not only a fine forage for bees and cattle, but it keeps the animals in splendid condition. It has the same feeding value as alfalfa, and the milk and butter from it are just as good.

Some one present asked him about getting cattle and hogs started on it. He recommended letting them loose when the plants are young and tender. For planting he advised putting in with early oats. The sweet-clover roots penetrate the soil deeply, and after two years die, allowing the moisture from beneath to come to the surface.

Asked as to the time when to cut it, he recommended that it be allowed to grow till it is 22 inches tall. The mower should be set so that it will not cut close to the ground—high enough so that some of the leaves will be left. Otherwise the plants will die.

Later in the afternoon the crowd was conducted by the Dadants to the big dam that furnishes 75,000 electrical horse power. The dam and the power plant are well worth seeing.

That evening we assembled—that is, those of us who were left—on the veranda of the

beautiful home of C. P. Dadant, which overlooks the Mississippi, the lake, and the great dam of the Keokuk Power Co. The time was taken up with impromptu speeches by Dr. E. F. Phillips, N. E. France, C. P. Dadant, and E. J. Baxter. It seemed appropriate to speak of the life and labors of men who have distinguished themselves in the beekeeping world—especially those who have passed away. Mr. F. C. Pellett, the presiding officer, called on Mr. Dadant to give some reminiscences of his father. He very modestly declined, saying he did not consider it either proper or appropriate to eulogize his own father, the founder of the firm of Dadant & Sons. Mr. Pellett then called on Dr. Phillips to respond to a toast, "Dr. Miller." There is probably no greater admirer of the Marengo beekeeper than

the representative from Washington. He spoke of the delightful visit he had had at Marengo, of Dr. Miller as a man, as a beekeeper, of his modesty, of his methods of comb-honey production, of swarm control. Mr. Pellett then called on your humble servant to speak of the life and work of the late W. Z. Hutchinson and the Rev. L. L. Langstroth. I felt that I was hardly big enough for the task, but I responded as best I could. But in closing I could not forbear referring to the sterling qualities of the late Charles Dadant; and later the chairman succeeded in drawing from Mr. C. P. Dadant, his son, a few further remarks. I was then followed by N. E. France, who spoke of his love for W. Z. Hutchinson, and of one man, Mr. Adam Grimm, who left his impression all over the state of Wisconsin,

for Mr. Grimm actually established a bank with the money he earned by keeping bees. Mr. Baxter then gave some further reminiscences of Mr. Charles Dadant. The talks were followed by some music by Miss Dadant, who was encored again and again.

THE INSPECTOR'S MEETING NEXT DAY.

Dr. Pammel, Botanist at the Iowa Agricultural College, read a paper on the subject of honey-plants and the importance of bees to the fruit-grower. A large number of specimens of plants, including heartsease, asters, Spanish needle, ironweed, etc., were brought in for his identification. This part of the program was interesting, as many local beekeepers were unable to identify many of the plants. There were several species of heartsease as well as of knotweed and smartweed. All of these Dr. Pammel named. Heartsease and Spanish needle were the plants that were, of course, furnishing so much

Staghorn sumac, *Rhus typhina* L. Photographed July 28, 1915, at Waldoboro, Maine, by John H. Lovell. Pistillate flower-clusters; in cluster on right the flowers are in bloom and are green in color; the cluster on left representing a later stage after the blooming period has closed, has turned crimson.

honey this year in the Mississippi Valley. He recommended that every beekeeper be familiar with the plants in his own locality that furnish honey. He called attention to the very intimate relation between bees and plant-life, and stated that every fruit-grower should keep some bees as a side line.

Dr. Pammel is doing some special work at the Agricultural College in classifying and identifying the principal honey-plants of the United States. If the result of this work comes out in bulletin form we are sure it will be of great value.

In the afternoon Dr. Phillips gave an address on general bee-inspection work. When he first came into the government work, only twelve states had bee-inspection laws. Now there are thirty states out of forty-eight that have some form of bee-inspection work. Most of the southern states have no laws, largely because bee diseases have not made any progress in the South. This is not because foul brood can not make rapid headway there, but rather because there are but few or no interstate shipments of bees from infected territory in the southern states. But the time will come when these states will need protection.

What is needed in the South, he said, is some one to teach modern methods of keeping bees. In this connection he claimed that it is the duty of a bee-inspector not only to treat bee-diseases but to give instruction concerning them. This part of the work is very important. Where bee-inspection laws have been properly enforced, there has been a marked decrease in the amount of bee-disease.

A bee-inspector should teach the importance of two things—first, plenty of bees in time for the harvest, and that means good wintering and good springing; second, keeping the bees together, and that means not to let them waste their substance in rictous living—or, more exactly, swarming. There is great need of general extension work in the southeastern states where there are more bees per square mile than anywhere else in the United States.

A paper from Mr. J. E. Crane, of Middlebury, Vt., who was absent, was read. He explained that the work of an inspector is not always pleasant. On the other hand he makes many pleasant acquaintances. Not knowing what Dr. Phillips had said, he went on to state that the inspector should instruct as well as inspect. He spoke of the difficulties of looking through hives when the frames were all glued together, or, worse, when the combs are built on no frames at all. He thought the states should

compel the use of modern movable-frame hives. He spoke of the difference between American and European foul brood; of the difference in treatment. The European type seems to move in the air. The American disease works slowly, but the European spreads with great rapidity. Robbers carrying diseased honey is not the only way that foul brood may be carried. Bees in their ordinary flights often make mistakes and get into other hives. In other words, drifting is a very common means of spreading disease. The ravages of European foul brood can be greatly mitigated by introducing a good strain of Italians, and keeping all colonies strong.

Staghorn sumac. *Rhus typhina* L. Photographed July 28, 1915, at Waldoboro, Maine, by John H. Lovell. Staminate flower-cluster.

Following this paper there was considerable discussion on the peculiarities of European foul brood. Mr. L. C. Dadant told how European foul brood in several apiaries had seemingly been carried by the queen. Several of the inspectors present, including Inspector A. L. Kildow of Illinois and his deputy, Inspector N. E. France of Wisconsin, and Inspector F. C. Pellett, had observed that European foul brood had been carried through the queen.

I put the question squarely to Dr. Phillips, who, up to this point, had not volunteered an opinion. He said frankly, "I do not know." In some private conversation with him afterward he thought there might be a chance for a mistake. While he did not

deny that it might be so carried, he thought we should do some more work covering a longer period before coming to the definite conclusion that queens can transmit European foul brood.

Mr. France, in one of his talks, went on to state that it had been claimed that American foul brood could be carried through foundation. He had always argued that it could not be so transmitted; but to satisfy himself he had some comb foundation made out of the rottenest combs he had even seen. This was placed in 62 different colonies, all of them healthy, but not one of them developed disease. Practically all of the inspectors agreed that American foul brood is not carried that way.

A THREE-FRAME NUCLEUS, AND WHAT IS POSSIBLE TO BE DONE WITH IT IN A SINGLE SEASON

BY R. J. T. MUCKLE

[On page 414, May 15, there is a picture of the "bonanza colony," and a brief mention of what was done with a three-frame nucleus and queen. On page 474 I called attention to this wonderful exploit, and suggested that there was a mistake in the date, as the letter sent us was evidently written carelessly and in haste. I am glad to tell you, however, there was no mistake, and that our good friend Muckle did exactly what he describes during 1914 with a three-frame nucleus received May 25. I asked him to give us full particulars of this wonderful increase, and he has kindly written it out in full as below.—A. I. R.]

Although a very busy man from 4 A. M. until dark I shall still try to answer your questions.

The whole thing was to me an experiment, or, rather, a continuation of an effort to prove Alexander wrong except in the plurality of queens. I succeeded only in proving him right, which was really what I *was* after.

From the afternoon of May 26, 1914, right through the season, I fed a gill of syrup (3 water, 1 sugar), not only to the original colony but to each swarm (artificial) right through the season up to October 20, when I gave those not sold 10 lbs. of sugar by measure to 4 by measure of water (2½ sugar to 1 water by measure). The queens being all young, and from the grand one accompanying the nucleus, simply filled their hives to overflow with young, and I was afraid the syrup would fail them before the spring of 1915, they having nothing else save the pollen in the two outer combs.

They came through in extra strong shape, and they withstood the worst spring and early summer I've seen in my life. So much for helping them and giving syrup for winter.

On May 26, 1914, I received a three-frame nucleus (value \$3.75) and a three-banded Italian queen (\$1.00), marked "a good queen." One frame was solid capped

worker brood, and the other two frames were fully half the same—not a drone-cell in the lot. The frames were swarming with workers and not over twenty drones; and the queen, a lively medium-sized one, was laying in 30 hours from arrival. She laid 37 combs full, twenty of which her gang drew out of full sheets of light foundation.

We certainly had an abnormal flow from dandelion. I never saw so many in my life before (and it was the same this year); wild fruits on a par, and wild mustard (in this country a good yielder), several hundred acres within two miles; also 20,000 acres of swamp land beginning one mile east.

On June 5 I put a queen and one frame of hatching brood in a new body, filling up with full sheets of foundation on wired frames. On this I placed a wire excluder, then a body full of drawn comb. Above this was a wire honey-board having two bee-escapes. Then having shaken two-thirds of the bees off the frames I placed the old body on top and the job was done.

Eight days later I cut out all but five queen-cells, four of which I put in queen-cages; and four days after I drew out a plug in the front end of the wire honey-board, putting on a five-inch-square alighting-board, and provided the top story (hatching-nest) with a hall door. My first queen mated; and when laying I moved to

a new stand with two frames of hatching brood, and bees clinging thereto. I then released a virgin, which was lost, and another, which was also lost (air full of dragon-flies); but the fourth mated, and it, too, formed a new colony. No. 5 was malformed, so I killed her.

On June 15 I switched again, this time by taking combs of brood out of the nest and putting it in the top story, filling their

places after drawing those left in the nest to the center of the body with full sheets, repeating this on the 25th and again on July 4.

That's all there is to it; but whether you will understand from my way of writing is another thing. Could I talk instead of writing I could make myself understood easier.

Clandeboye, Man.

THE BEEMAN'S OPPORTUNITY

BY L. M. GRAVELY

Beekeepers as a rule do not realize what an opportunity they have by way of securing free advertising. If properly managed, one can even get pay for advertising his own business. The rank and file of the honey-consumers never understand the marvelous things of interest concerning the bee and its works. It is up to us to give them, through the medium of the newspapers, live, interesting sketches of the bee and honey industry. Anything unique, original, or interesting is acceptable. Of course, one must not give the article the appearance of advertising or it will "queer the game." It is not necessary to say that you have honey or bees to sell. If you have bees they will know that you have honey.

I produce a ton of honey. The word "ton" seems much bigger when applied to honey than does 2000 pounds. So does half a ton, or a quarter, for it seems much bigger to most people because they were familiar with it only in spoonful lots when given to cure a cold.

Then, again, the average person cannot get away from the belief that you are taking your life in your hands. Most beekeepers can amaze the public by the way they handle their bees. One of the most successful plans I ever tried in the way of advertising was the use of the accompanying illustration. More for the fun of it than anything else, I made this picture last summer, showing a real live swarm of bees on my head.

A hat that is truly alive.

Ringgold, Va.

A NEW ABSORBENT COVER

BY G. A. BARBISCH

My bees are wintered in the cemented cellar under the house. This cellar has good ventilation, the thermometer seldom varying more than four or five degrees all winter, no matter how cold it is outside. With the exception of one season I have had no loss

whatever in this cellar. My bees are stacked up in tiers of four, but every spring I found that colonies in the lowest tier next to the floor had moldy combs and were always the weakest in bees.

Last season a certain bee-supply com-

pany sent me a sample of a new absorbent cover made from flax fiber, claiming these covers would absorb all moisture in the hive, and that no more moldy combs would be found. I at once ordered enough of these combs for all my hives. They were put on the hives two weeks before the bees went into the cellar. Here I might also mention that all our bees are covered in the fall with tar paper, just as soon as we can take off the extracting-super, and we think it pays well. Bees that are covered with tar paper can be kept out longer than if not covered. Then, too, if an unexpected snow-storm comes during the night, your bees are still dry and snug. Very often we have stormy weather in November, while in December it is nice, and bees still can have an occasional flight. These are the reasons why we cover our bees with tar paper.

But, to go back to my subject, seventy-five colonies went into winter quarters Dec. 10. I left off the regular covers and substituted these flax covers. They were confined just four months, and after examin-

ing in the spring I was gratified to see that, among the seventy-five colonies, not a single wet or moldy comb was found. All the colonies were alive, and all the hives were as clean and dry as they could be. After all those four months of confinement, about two quarts of dead bees were swept up in all.

This proves beyond a doubt that these flax-fiber covers are of great value where bees are wintered in the cellar, and especially where a cellar is damp and cold. They are also fine outside for spring protection providing one uses the metal-roof covers. If used with the excelsior cover they are of no value, as they are the same width as the hive. If a hard rain comes it strikes the edges of the cover and soaks the cover like a sponge. They cannot be left on all summer, as the bees glue them down so that they break when you want to take them off. As I said above, however, when one winters his bees in the cellar they are indispensable, and the cost is so low that it pays well to use them.

La Crescent, Minn.

A WHEEL HOE CONVERTED INTO A SPRING WHEELBARROW

BY F. J. LEE

The picture shows my spring wheelbarrow for taking bees in and out of the cellar. I used to hire a man to help me, and one of us had to go backward some thirty feet through the furnace-room to the bee-cellar. With the spring barrow I can take the bees out easier alone.

Every beekeeper has or should have a garden, and a wheel hoe or seeder to work

it. Here is how to change the wheel hoe to a wheelbarrow. Turn it bottom side up; take off the hoe or rake; take off the handles; turn them over; bolt them on again. Take two sticks for legs, and two pieces of lath for braces. Two small bolts will fasten the legs to the handles, and four one-inch screws the braces. Now cut six pieces of board 18 inches long. Hunt up six old

A light spring wheelbarrow made from a wheel hoe—just right for carrying hives into the cellar.

springs, and put them between the boards and fasten them well with spacing-staples. Two pieces of lath on each side will hold the boards in place. Fasten the bottom boards to the handles with some hay-wire; put on a narrow piece for a dashboard, and

the spring wheelbarrow is complete. I was less than half a day making it, and I can change it back to a wheel hoe in less than five minutes. Mine weighs complete only 22 lbs.

Lee Valley, Ont., Can.

HOME-MARKET PROTECTION

BY W. I. LIVELY

Of all the problems which confront the beekeeper, that of marketing his crop is one of the most trying and difficult. Honey is not the staple article of food that it should be; but the campaigns to educate people to its value as a food are doing much to increase the consumption; and more intelligent methods of marketing would greatly relieve the situation. Beekeepers generally pay too little attention to their local markets. There is too much of a tendency to rely upon the wholesale business to plate the crop before the consumer. It does it after a fashion, but at a loss to the producer and a higher cost to the consumer, both of which militate against the business of beekeeping.

Some time ago, through conversations with traveling salesmen, I learned that Arizona honey was selling in California, and California honey in Arizona, both at prices which would spell bankruptcy to the producer if they continued. Practically, the beekeeper was paying freight and middleman's profits for the privilege of selling his product in a neighboring state. The same thing is being done constantly all over the country. The shorter the distance and the fewer the middlemen between the producer and the consumer, the greater the profits to the producer, and the smaller the cost to the consumer.

Now, that does not mean to sell at any old starvation price in order to unload your crop at home. *Above all, protect your home market and protect your fellow beekeeper.* During the seasons of 1912 and 1913 I worked up a nice market in a city some distance from my home. In the fall of 1914 the war and other causes depressed the shipping market. Other beekeepers, some of whom I knew, and who are fine, well-meaning fellows, followed my footsteps and flooded the city with their brands at a price with which I could not afford to compete. The result was that I lost practically all my trade there. I found the method of selling was something like the following: Mr. A. took some samples to a merchant and offered honey for sale. The

merchant asked his price and he named it. The merchant informed him that he could buy from Mr. B. at a lower figure, and generally this was the case, though not always. Mr. A. then offered to sell a trifle under Mr. B., and closed a sale. Mr. C. then undersold both of them, and, like the story of the little fleas, this continued "*ad infinitum*" until the price reached a level below the cost of production. I found men selling honey in three, five, and ten pound packages at practically the same price they were getting for it in sixty-pound cans. Others were disposing of from five to ten gallons at the same price for which it was being shipped in earload lots. It is passing strange that men with intelligence enough to raise bees and harvest a crop of honey should show such a lack of common sense in disposing of it.

This season, with the outside market "shot to pieces," and times not up to normal, I marketed my entire crop, amounting to nearly seventeen thousand pounds, at a reasonable figure, and not a pound of it went outside my home state. I have orders on file now which will take probably half my coming crop. Of course it takes time, patience, hard work, and good judgment; but it can be done by others as well as myself. I set my price and sell at my price, or do not sell at all. I am not unreasonable. I ask only a fair price; and when I cannot get a price for my crop which pays me for my time and labor spent in raising it I shall quit the business.

Now lastly, and most important of all, if you wish to make a success of home marketing, *protect your home merchant.* In the city which I mentioned above, the merchant complained that their sales were very slow, and honey was a drug on the market. I soon found out the reason. The beemen were peddling their wares from house to house, and selling at the very same price that they were selling to the merchants. Their wholesale and retail prices were identical. When the merchant finds out the true state of affairs, as he is sure to do in a short time, his only recourse is to put his buying

price below the beekeeper's selling price so as to make his legitimate profit. Thus the beekeeper, by making his wholesale and retail prices the same, has cut his wholesale still lower. Besides, there is no surer way of getting on a merchant's blacklist.

The plan I follow is this: I go to some of my home merchants with whom I am well acquainted, and whom I know to be shrewd, honest business men. I consult with them as to prices, find what they consider a fair retail margin, which is generally from fifteen to twenty per cent. We agree on a wholesale and retail price, and both sell at the same price. For example, I carry a ten-pound pail as one of my leaders. I wholesale it to the merchant at eighty cents, and sell to any and all wholesalers at that price unless in job-lot quantities of several hundred, when a small additional margin is allowed. The merchant retails it at one dollar. I retail it at the same, whether it is bought at my apiary or delivered to the customer's door, and *I never peddle among the merchant's customers.* It would be business suicide, so far as that merchant's patronage is concerned. I simply give the merchant a square deal, and invariably he returns it. I guarantee my goods to the merchant, and request him to guarantee them to the customer. I put up nothing but the best, and back it up with a "money back if not satisfied" proposition, and protect the retailer by standing good for any goods returned. During the last three years I have had only two or three pails sent back. In dealing with a

The bees had built six combs of brood and two of honey. Query: Had these bees been accustomed to an eight-frame hive?

business man a pleasant, courteous, business-like manner, coupled with honest dealing and fair treatment, will gain you a friend and hold a customer.

Glendale, Ariz.

ANOTHER FRESH-AIR COLONY

BY IONA FOWLS

We learned the other day of a very progressive colony of bees that have evidently been influenced by the fresh-air agitation, for they have taken up their abode outdoors with the apparent intention of staying all winter. We took a 28-mile drive to hunt them up. We found them located near the river on a farm between Wakeman and Birmingham. They were suspended at the end of a long limb hang-

ing out over a very steep bank so that we had a rather exciting time getting their picture.

At first all we saw was a large cluster of bees; but by smoking them back we finally exposed the combs to view and found they had built two good combs of honey and six of brood, the combs being arranged exactly parallel to each other, and very nicely spaced.

Oberlin, Ohio, Sept. 18.

A PRECAUTION WHICH IS GENERALLY OVERLOOKED

BY R. KEEP

It is surprising that the simplest thing is overlooked so often. The best conditions for wintering are so varied and so much in dispute that no trustworthy rule can be es-

tablished. One person claims best results by packing so warmly, regardless of expense, as to have no trouble with condensed moisture; another puts his faith in upward

ventilation and absorbents; another says, "Let them take their chance *à la Nature*."

But, to consider actual conditions, it is next to impossible to avoid condensation, at least to some extent, and the absorption of condensed moisture by the hive walls and cover is ruinous to a degree. Another prevents this most effectually by coating those surfaces with melted paraffin, and then, to get rid of the water of condensation in the quickest way, tips his hives forward during winter by putting two or more inch blocks under the back end. This position in winter is beneficial in two ways at least. It

brings the entrance into a position which is less exposed, and it positively prevents snow water and rain from running in. And—most important of all—the condensation on the under side of the cover clings to it long enough to run to the lowest (front) end before it drips. The bee cluster is thus saved a fatal wetting.

Many beekeepers to whom I have suggested this have said, "Why, I never thought of that!" Just another case of the simplest thing overlooked. It is said, "The world is made up of small things"—and beekeeping no less.

Lyndhurst, N. J.

AN INTERESTING DIARY RECORD OF WEATHER CONDITIONS IN WASHINGTON

BY A. M'CULLEY

Several times I have been tempted to mention instances of bees flying with the thermometer standing at 18 above, but have refrained from doing so as some would ask what I had been drinking. This is a queer country. The following readings were taken in the morning when I got up. Perhaps before noon there would be from ten to thirty degrees' difference in temperature.

Oct. 26, 1904, first frost; Nov. 13, 2:30 P. M., rain; Nov. 14, wind a gale. Rain hard 15th and 16th. Dec. 31, beautiful sunshine; air chilly.

Feb. 4, 1905, beautiful weather; thermometer 28 above; 8, 9, 10, 13 to 20, ther. 15 above. Feb. 21, very warm. March 20, 21, 25, rain, cold; 29, sunshine; warm. May 6, caught a swarm of bees. Nov. 28, first snow; 29, snow all gone.

March 10, 1906, commenced to get cold. March 12, cold—ther. 28 to 26 degrees above. March 15, ther. 10 above. Dec. 30, first snow today.

Jan. 14, 1907, ther. 2 above. Feb. 10, warm, pleasant; drones flying. April 22, frost; ther. 32. Bees swarmed today. Dec. 1, cut a tree for bees; bees 210 feet high; ther. 64; tree 7 feet through.

Jan. 5, 1908, bees flying. Jan. 23, ther. 54 in shade. Dec. 26, bees flying as in summer.

Feb. 2, quite warm and pleasant. Bees had a good fly March 4 to 8; lots of brood. March 9, 1908, bees flying as in summer. March 20, first swallows. Sept. 25, frost, very heavy; no damage. Nov. 3 to 8, very warm; ther. 64 in shade; bees carrying pollen. Nov. 15, 19, 23, bees carrying pollen. Dec. 1, 2, 3, ther. 28 to 26 above; bees flying. Dec. 13, 17, ther. 28, bees flying; Dec. 18, ther. 16.

Jan. 4, 1909, first snow; Jan. 5, ther. 8 above; 5 inches of snow. Jan. 9, ther. 2 above; 11 to 14, ther. 1 above; river frozen over. Feb. 10, 11, ther. 29 above; bees flying. Feb. 18, very warm. Nov. 13, first frost, ther. 30. Nov. 14, 15, ther. 18 above; Nov. 18, 20, ther. 55. Dec. 4, 5, ther. 22 to 18; no wind; a little snow. Dec. 28, snow and wind, blizzard.

Jan. 2, 1910, clear and cold; ther. 10 above. Jan. 6 to 10, rain; ther. 22; a few flakes of snow. Jan. 14, warm; ther. 40; bees had a good fly. Jan. 20, freezing; ther. 28. Jan. 22, ther. 50; bees flying as in summer. Feb. 1, ther. 28 to 32, cold. Feb. 6, 7, bees flying as in summer. Feb. 8 to 10, warm; ther. 48 in shade; bees flying, carrying pollen. Feb. 16, 17, ther. 16; 6½ inches of snow. Feb. 21, ther. 20; snow, cold; ground just covered with snow. Feb. 23, ther. 28; snow 4 inches; rain. Feb. 24, rain; ther. 36. Feb. 26, ther. 38. Feb. 27, ther. 42. March 2 to 10, warm wind; ther. 48. March 10, ther. 60; bees heavy with pollen. March 12, ther. 60 in shade; wind from north. March 16, warm; ther. 64 in shade. March 26, ther. 28. April 5, rain; ther. 42. April 4, first swallows today. April 14, ther. 42 in shade at 8 A.M.; 9:30, 72 in sun. April 18, no fire in office; ther. 72 in shade. Sept. 10, heavy white frost this morning; froze hard in some places. Dec. 30, first snow, 1¼ inches; ther. 28.

Jan. 3, 1911, snow gone. Jan. 5, ther. 41. Jan. 9, 10, 11, snow; ther. 26 above. Jan. 12, 13, 14, ther. 18, 8, and 22; snow heavy; sunshine at the same time. Jan. 15, 16, 17, ther. 12, 38, 34; rain. Jan. 27 to 29, ther. 28; foggy. Jan. 34, ther. 34; bees flying. Feb. 2, ther. 18 above. Feb. 8 to 11, ther. 48; bees flying as in summer,

very strong. Feb. 20, foggy morning, sunshine afternoon; ther. 38 to 44; bees carrying pollen. Feb. 23, ther. 44; rain, snow, wind, all at the same time. Feb. 24, 25, 26, 27, ther. 20 in shade, 64 in sun; bees carrying pollen. March 2, 3, 4, ther. 32 to 72. March 12, 18, ther. 34 and 26; March 23, high wind, 40 miles per hour from southwest. April 1, ther. 38. April 5, white frost; ther. 28. April 11, 12, three inches of snow. April 13, frost. June 19, 20, white frost; no damage. Oct. 1, went above Evans, 7 miles; got a swarm of bees hanging on a log—small colony. Nov. 10, 11, snow $5\frac{1}{2}$ inches. Nov. 11, ther. 8 above. Nov. 13, rain, thaw. Nov. 27, bees carrying pollen. Dec. 1, bees flying nicely; ther. 42. Dec. 30, 31, snow $5\frac{1}{2}$ inches.

Jan. 1, 1912, clear and cold. Jan. 14, ther. 48; bees flying almost like swarming; very strong. Jan. 18, 19, warm, bees flying as in summer; ther. 45. Jan. 20, bees flying; very warm like summer; willows bloom; dandelion bloom. Jan. 28, 29, ther. 50 to 62; bees flying as in summer. Feb. 11, 12, ther. 54; bees carrying pollen; good. March 8, ther. 78 in sun; wind from north; cool. Dec. 12, a light spit of snow.

Jan. 6, 1913, 8 inches of snow; ther. 28. Jan. 17, rain; snow going. Jan. 18, snowing hard; ther. 28. Jan. 19, ther. 10 above. Jan. 23, rain; no snow. Jan. 24, 25, bees flying; ther. 44. Feb. 6, 7, ther. 40. Feb. 23, ther. 20 at 8 A. M. March 1, ther. 40; bees flying as in summer. March 11, 13, heavy thunder; ther. 28. March 18, snow falling; ther. 30. March 19, ther. 26; three inches of snow. March 20, ther. 18; some snow. March 24, 25, snow; ther. 20 to 26. March 27, cloudy; ther. 50. March 30, 31, ther. 58. April 7, first swallow; ther. 38. April 8, white frost. April 10, ther. 72. April 11, ther. 110 in sun, 92 on wall in shade. April 11, evening, rain; cooler. April 27, ther. 62 in shade. May 4, frost; ther. 32. May 10, 11, warm; rain; ther. 76 in shade. Oct. 7, 8, 9, ther. 40. Oct. 13, some thunder; ther. 28. Oct. 21, ther. 50. Oct. 28, ther. 22. Nov. 14, ther. 26. Dec. 1, 2, 3, 4, cold foggy; ther. 28. Dec. 15, 16, ther. 50; barometer fair. Dec. 21, ther. 26.

Jan. 11, 1914, ther. 40. Jan. 22, light snow. Jan. 24, ther. 26; snowing heavy; 27, snow 2 inches; ther. 20. Feb. 4, ther. 18. Feb. 5, 6, ther. 28 to 30; bees flying. Snohomish, Wash.

THE RESULT OF THE SEASON IN NORTH VERMONT

BY JEAN WHITE

Bees in the northern part of the state have not done much this season. They wintered very unevenly, some losing all or nearly all, some half, and some losing none. One farmer with a few colonies left one out without extra covering of any kind in a single-walled hive. It was a late swarm from 1914, with seemingly but little to winter on. We had but little snow, so this did not protect the hives, yet this swarm was alive and frisky enough so that it swarmed twice this summer. The other hives in the house-cellar also wintered well.

One neighbor less than half a mile away lost all in the house cellar with dysentery. Another within a third of a mile lost out of some thirty colonies put in the house cellar, all but sixteen. Another, a mile away, put in five and wintered them all; while another with five in a bee-house lost all but one, and this was weak. This colony did not swarm this season, but finished a nice super of honey, and has the body full of brood and honey.

Bees in my neighborhood swarmed very freely, and have done no work, to amount to anything, in the supers. I tried artificial

swarming by raising a frame of brood with the queen, over the main hive, and separating when she had several empty combs filled with eggs and brood. This left the workers with the old hive and new queen and full of bees, but they did nothing in the supers until after the clover flow was over in August. The new hive is full of bees, brood, and honey; but even the outside frame of a ten-frame hive has beebread and some brood in it, so they have plainly fixed it so I can't extract any honey without destroying some of their numerous family. They did not swarm, however, so the two colonies are very strong. The spring until June 20 was cold and dry; but the pastures were white with the low white clover. My own theory of lack of surplus is that many field bees never got back to the hive when the winds were high and cold, and so the force was not large enough to gather a surplus. Since that time it has been wet and warm. I tried to feed my bees after haying time, but they refused it, so of course they were getting all they needed of something they liked better.

Last year at the close of haying all the

bees within a mile went on a rampage. They hung around the house doors and windows, robbed out weak colonies, and were a nuisance generally. I tried to feed; but the hives with empty bodies on, and food in these, were black with robbers from a neighbor's apiary trying to get the syrup. The berries were covered with them—as many, sometimes, as three on one raspberry. This year there are no bees in the berry-patch at all. Last year many berries were sucked as dry as though dried by artificial heat; this year there are no such berries, and no bees there other than now and then a little yellow wasp.

It seems that the bees must go into winter quarters in the best of condition; but our profits for honey this year are small. There are no large apiaries in the north of the state, and most of those who keep them allow them to swarm naturally. I am thinking that next season I will remove a frame or two of brood and the old queen from the hives as a nucleus for a new swarm, and introduce a young queen to the parent hive without waiting for them to raise one themselves, and see how that works. I am also minded to try the Pearce method with one hive, except that I shall not put them in a window but leave them on their stand.

Unlike most people who handle bees I have never used a smoker. I often open the top of my hives without gloves or veil; but if I plan to handle frames I put on both; and by moving quietly they do not get much excited. All through the spring they do not seem to resent being handled at all, especially if I have been feeding them; but later, when they have stores of

new honey that must be disturbed, they are somewhat indignant, but nothing fierce after all. I think I have a very gentle race of bees, however, because those I had some time ago were much more difficult to handle, and I tried a smoker; but the smoker bothered me more than it quieted the bees, and so I discarded it altogether.

I have been putting starters in some frames. I had no foundation, and could not wait to send for any; so I took some empty worker comb and cut strips $1\frac{1}{2}$ inches wide, and fitted these into the frames and tied them in snugly. The bees seem to like this very much. They fastened it, then cut out the string, carried it out of the hive, and are busily building more comb. I think that next time I will fasten it to the frame with beeswax and rosin, and save them the trouble of gnawing off the strings.

We are told that it does not pay to make our own hives; yet that is just my plan for another year. Our supplies have to come several hundred miles, and the freight on a five-hive lot is considerable. They must be nailed together and painted anyhow, unless one feels able to buy them all ready, which makes them cost high. I will have the bodies, supers, tops, and bottoms sawed from lumber here, and will send for the inside fittings. There is about twelve feet of lumber in a body, super, etc. Lumber is about two cents a foot undressed. If properly cut, it will be no more work to set it up than to set up those I buy. The saving will be the greatest cost, and this will not be heavy in this locality. May be I am counting my chickens unhatched—anyhow, I will tell you by and by how I come out.

Glover, Vt.

SEPTEMBER SWARMS

BY H. M. LEACH

The past season has been the most remarkable I have ever known. During June, July, and August, only a small amount of honey was stored; but, beginning with the last week of August, and so far this month, my bees have stored many pounds of fine light-colored honey. One colony in ten days filled and capped a 32-section super. Now, what has interested me most, and seemed unusual, is the swarming.

Some of my colonies cast large swarms as early as May 17, and during the first and second week of September they have cast large swarms again. The new swarms are doing well. What would cause them to start

swarming in September when they were furnished plenty of room to work? Some of my neighbors have had the same experience with swarming this month. My last swarm came Sept. 16. It was a large strong swarm, and is getting along well. From my six largest colonies I shall get 500 pounds extracted and comb honey, and all made since August 20. No dark honey has been stored in supers.

I have had bees swarm but once before in September, and that was twenty years ago. Hiram, O., Sept. 20.

[See editorial last issue.—ED.]

Heads of Grain from Different Fields

The Backlot Buzzer

BY J. H. DONAHY

With one glance at the outside of a hive, an expert beekeeper can tell what is going on within, but in goldenrod season he don't need to look at all. He just smells 'em.

Why Packing Material or Absorbents Become Wet

I am especially anxious to get some advice from you relative to a point involved in wintering bees. Some of my hives are single-walled, some double-walled. Heretofore I have, when putting them in shape for winter (I winter on summer stands) placed three or four small sticks, each about the size of a corncob, crosswise directly on top of the brood-frames. Over this I put a piece of burlap. Then I put on a super, filling it with sawdust or shavings. In the case of the double-walled hives this material would be dry in the spring. In the case of nearly all the single-walled hives the contents of the super just above the brood-frames were wet in the spring. On the single-walled hives I put a covering of newspapers (that is, on the sides), and over all I put a sort of jacket of tar paper. I have wondered if at least, in the case of the single-walled hives, I should put a super cover directly over the frames instead of the burlap.

Bees in this section of the country have been unusually cross this year. There has been much complaint. Can you suggest any reason for this?

A farmer has complained to me about his bees hanging around his barn a great deal. I told him that I would look into the matter. I can think of no odor that would attract them there. Perhaps you can give a possible explanation.

Chadron, Neb., Sept. 11.

E. P. WILSON.

[We are not surprised at your experience. When the packing material is too scant in amount there will be a great deal of condensation inside of the hive. This naturally passes upward, making the packing damp; and when the weather is severely cold this damp packing will freeze. It is then worse than no protection at all. When single-walled hives are used there should be a sealed cover between the packing and the colony. If double-walled hives are in use, there should be a sealed cover unless the packing material is very abundant on top and sides—not less than six inches on sides and cuds nor less than ten inches on top. Under such conditions Dr. Phillips says it will not make very much difference whether a plain board or a porous cover is used over the brood-nest. The general practice, however, when packing is ample, anywhere from six to ten inches, is to use the absorbent plan. But when so used there must be a space over the top of the packing, leaving room for the free circulation of air through ventilating holes in the cover at the ends. When a sealed cover is used these ventilators are not needed. We would advise you to use a super cover on your single-walled hives, wrapped in paper, and possibly a sealed cover for double-walled hives. If the packing material is less than ten inches on top, and three inches on the sides and ends, we would use a super cover.

Some seasons bees are much crosser than at others. They will be very cross when the flow is intermittent, especially if it comes on heavily and shuts off during the middle hours of the day. This is one reason why bees are so cross during a buckwheat flow. They are also cross when they work on honey-dew. The dews of the morning soften the saccharine matter on the leaves, and then the bees work on it at a furious rate. As soon as the sun dries up this sticky stuff the bees stop their work, and then they are cross—awfully so. Sometimes the honey-flow is intermittent on clover, basswood, the goldenrods, and the asters. When the yield stops suddenly on account of rain or cold, the bees will become cross. Chilly weather is apt to make bees cross at any time.

When bees frequent barns or stables they are undoubtedly in quest of artificial pollen which they obtain from the bran or meal in the chopped feed given to the cows or chickens. They may be quite troublesome at such times; but as soon as natural pollen is available they will immediately drop the artificial product.—ED.]

Requeening with Queen-cells Not Satisfactory; Difficulty of Raising Cells where there has been European Foul Brood

Having read so much about requeening by using ripe queen-cells I attempted to requeen a number of colonies by that method this season; but only about one queen out of each dozen reached laying age. At first I used cells from which the queens were ready to emerge; but after reading Mr. Doolittle's definition of a ripe queen-cell, which he says is a cell from which the queen is to emerge in from 20 to 30 hours, I thought that my trouble lay there; but after trying a number of cells of that age I could do no better. Very rarely were the cells destroyed; but the virgins disappeared, and the colonies tried to rear queens of their own brood. It did not seem to make any difference whether the colony was Italian or black. The colonies which were hopelessly queenless did better, but not satisfactorily.

I have been having quite a fight with European foul brood, and have found that in colonies where there has been any of the disease during the season

it is almost impossible to rear queens artificially, for the larvae almost always die. Even in colonies that showed no trace of the disease among other brood, it would develop in the queen-cells. The giving of Italian queens after keeping the colonies queenless for ten days or longer removed all traces of the disease among worker and drone brood in all but two colonies, and these were not very strong when the queens were introduced; so the queens were removed and brood given from healthy colonies from which they succeeded in raising queens, and there are no traces of disease among them since the young queens have begun laying.

I tried the McEvoy plan of treatment at first, but found it useless, as the bees were all blacks. It did succeed, however, with an isolated colony of a neighbor, though they were almost if not quite pure Italians.

Tangent, Ore., Sept. 23.

H. E. WEISNER.

[Your difficulty in requeening by the use of ripe queen-cells is rather unusual. We don't know how to account for it unless it was the peculiar season we have been having of rainy, cool, and chilly weather. Our own queen-rearing operations early in the summer were greatly handicapped, and we attribute it to the bad weather. During bad days many virgins would get lost—at least a much larger percentage than usual would fail to mate.

We have not heard of cases before where the larvae in queen-cells would die in colonies where there had previously been European foul brood. Have others had a similar experience? It would look as if European foul brood could be in a colony and not show itself in the worker brood.—ED.]

Well-known Beekeeper Loses Hand in Circular Saw

Dear Mr. Root:—I fell on a circular saw yesterday, and cut off all my fingers and the thumb of my left hand, and I want you to help me in my trouble. You must have among your fifty thousand readers some beekeepers who are or have been in the same predicament as myself, and who can, perhaps, suggest some attachment that I can get made to put on the palm of my hand to enable me to pull combs out of the hives and carry on my business as a beekeeper. I can hear of no artificial fingers here, although I am told I can get an artificial hand if I have mine cut off at the wrist. If any one can make any suggestions, will he kindly come along and thus help a brother beekeeper who has a large business to attend to, and a large family to maintain?

MAJOR SHALLARD.

South Woodburn, N. S. W., Australia, Aug. 17.

[If any of our readers can suggest anything we are sure that our friend would appreciate it if they would communicate with him direct. It is fortunate indeed that it is the left hand and not the right.

Mr. Shallard is greatly worried, of course. The accident took place Aug. 16. With the spring in Australia opening about Sept. 1, it is not hard to realize that such a handicap is indeed serious.—ED.]

No Trouble in Wintering

It has been our practice for the past few years to winter the extracting-supers on the hives. Some are placed above and some below as the case may be. Our plan is to extract during midsummer, and place the supers back on the hives, with the usual queen-excluder between.

During the fall, after the aster flow, we examine all hives for winter stores, and test by weight. Those found with just sufficient stores, or a little more, are merely left alone, after removing the excluder, giving the queen access to the twenty frames.

The honey will be found partly in all of the frames, both above and below; so if we extracted the upper set, we would have to feed back into the lower to have sufficient stores.

Those found with most of the stores in the lower are sometimes simply reversed. Entrances are closed down with the usual stick furnished with bottom-boards, and about 6 x 3/4-inch opening, which effectually excludes mice. We are never troubled with robbers. When the bees are wintering in the upper super the lower stores are generally sealed, and do not give off sufficient odor to attract. Besides, it is cold and dark on bright days in the lower brood-bodies, and strange bees do not readily enter. And then, again, when it is sufficiently warm the occupants of the hives are down on deck and on guard.

We find in the double hives that the bees do not come out as often as those in a single body, and, furthermore, breed up quicker and stronger in the spring. The frames are protected from moths, which is another advantage. Some of these twenty-frame hives are shaken down the following early summer and used for comb honey. Others, again, are run for extracted after locating the queen and placing that super below, with the queen-excluder between. We winter on the summer stands, and never have any trouble with aster stores.

Cincinnati, Ohio.

J. E. ROEBLING.

Empty Super under Colonies Wintered in a Cellar

Last fall I put ten-frame hive-bodies full of honey over five very strong colonies. The bees worked up into the upper hive-bodies. Very few bees died. I put an empty super under a strong colony and another empty super under a weak colony to observe the effect. Less than a hundred bees died in either colony. All the hives are set on bottom-boards two inches deep with screen in front. The temperature of the cellar where they are kept was from 42 to 50 degrees. The hygrometer showed moisture from 20 to 60. The cellar is ventilated by a chimney, and has a cement bottom in which is a spring of water covered by a plank. I used a fire in a wood-burning stove occasionally, to dry excess moisture. I wintered thirty colonies and lost none. I shall put empty supers under all my colonies this fall.

Plymouth, N. H.

GEO. W. DOLLOFF.

Home-made Mittens

On page 527, July 1, Grace Allen asks, "Shall we wear gloves?" This reminds me that when I began handling bees I did not use either gloves or mittens; but as I sometimes got my hands so badly stung I soon decided to change. For years I have used mittens which my wife makes of medium-weight bed-ticking, with the ticking cut so as to make the part for the fore finger like the fore finger of a glove. The wrist is made flaring, and is about six inches long so as to come up over the sleeve of whatever garment is worn. If such mittens are made to fit neatly they will be quite satisfactory—at least I have so found them.

Huntington, Ind.

J. W. SOUTHWOOD.

What would the Coroner Decide?

Who can describe the appearance of a larva that died from arsenical poisoning as distinguished from a larva dead from pickled brood, chilled brood, or some other familiar cause?

One consolation to those of us who find our bees on starvation rations now when there normally would be a surplus in the supers is that this is great weather for producing white clover for next year's crop.

BENJAMIN F. KIRK

Can Honey with a Coal-oil Flavor be Safely Fed to Bees?

Have you had the experience of feeding bees "coal-oil flavor" extracted honey, or has the matter ever been called to your attention as to whether or not it is harmful to the bees? In a carload of honey that we recently unloaded there were over 20 cans that taste and smell of coal oil, oil-cans having apparently been used without being freed from traces of oil. If not harmful to the bees, we can use it for feeding purposes after boiling, to make sure that there is no foul brood as a result, in which event we wish to settle with the shipper in full, as he is a good customer of ours.

Ggden, Utah, Sept. 29. F. W. REDFIELD.

[We have never had any experience in feeding bees honey having "coal-oil flavor." Something would depend on the amount of coal oil in the honey. If it merely smells of the fluid and tastes of it slightly we would not think it would do any harm, especially if you boiled it to sterilize it from any possible infection. While, of course, the kerosene flavor would ruin it for human consumption we see no reason why it could not be used for the bees.

If any of our readers have had any experience we hope they will send it to GLEANINGS.

Incidentally this shows the folly of using second-hand kerosene oil-cans that have not been thoroughly cleaned and aired. They are always dangerous to use.—Ed.]

A Swarm from a Colony Packed for Winter!

The weather here has been very unsettled. Expecting an early fall, I fed most of my colonies and packed them for winter.

In the last ten days conditions have changed so materially that I received from one of my colonies, which had been packed for winter, a prime swarm. This has never occurred before in my experience of twenty-five years with bees. White clover at this time is still blooming, but I do not think that there is much nectar secured.

It would gladden the heart of any beekeeper to see, as far as the eye can reach, our solid sea of gold—the Spanish needle. Bees are working on it from early morning until the blossoms close at sundown.

Our colonies that have been put away for winter were very weak in stores, and I fed them. This expense I could have saved if I had known the weather would change so favorably. The thermometer has been between 70 and 80 every day.

Stratford, Mo., Sept. 8. T. SCHARFF.

Kootenay Beekeepers' Meet

The first annual meeting of the Kootenay Beekeepers' Association was held at the City Hall, Nelson, on Friday, Sept. 24, the last day of the Nelson Fruit Fair, at which there was a representative attendance of members from Nelson and the surrounding districts. The report is as follows:

The Association, organized in September, 1914, is the first beekeepers' association to be formed in British Columbia. Seventy-eight members have been enrolled. Unfortunately the past season has not been a good one for honey production in this section of the Province. Exceptionally fine and warm weather prevailed during March and April, when the bees went ahead and promised well; but the three following months—May, June, and July, were excessively wet and cold. Consequently the clover on which we mainly depend for our surplus honey crop yielded but very little nectar.

The honey that has been taken is much darker in color than usual. In many instances colonies were actually starving in June, and would have succumbed had they not been fed with sugar syrup.

The honey-label adopted by the association for the use of the members, to promote uniformity in putting up honey for sale, has met with general approval, and 3825 have been sold to date.

The balance sheet, showing an excess of assets over liabilities of \$43.25, was approved.

The following officers were elected for the year ending September 30, 1916:

Hon. President, W. E. Scott, Deputy Minister of Agriculture, Victoria; President, Major-General Lord Aylmer, Queens Bay; vice-presidents, G. E. Parham, superintendent Dominion Experimental Farm, Invermere; G. Fleming, Nelson. Executive committee, J. J. Campbell, Willow Point; Mrs. Casler, Nelson; J. Hyslop, Nelson; C. G. Johnson, Nelson; W. H. Rixen, Nelson; W. J. Mohr, Nelson; J. Blinco, Creston; B. Lockwood, Fruitvale; E. Alpagh, Kaslo; R. E. Plewman, Rossland; J. H. Vestrup, Nakusp; H. W. Collins, Grand Forks; H. G. Slater, Westley; T. S. Gill, Cranbrook; G. F. Attree, Queens Bay; James Johnstone, Nelson; W. Romain, Nelson; A. E. Watts, Wattsburg; Hon. secretary-treasurer, W. J. Sheppard, Nelson, Hon. auditor, T. M. Rixen, Nelson.

Great Storm in Jamaica

We had a terrific storm in this country on August 12 and 13. It began on Thursday evening of the 12th, and lasted until noon of the 13th. It has done much harm to the honey crop in this part of the country. We were expecting a good crop of honey from the soapwood-trees. The storm flogged their blossoms off and destroyed some of the bees. The banana plantations are all destroyed. This plant is one of our staple crops, yielding honey all the year round. The bees are in quite a delicate position. About half of the field bees were lost in the storm, and about one-fifth of young hives were destroyed in two of my apiaries along the banks of the river. We hope that a change will take place in this locality that the bees may get some honey.

J. U. V. McCORMACK.

Stonyville Gayle, Jamaica, Aug. 25.

We use a carpenter's scraper to scrape honey-sections. This is a piece of steel 2 x 3 inches, with perfectly square edges. When it gets dull you can put it in a vise and sharpen with a flat file. We like it better than a knife.

Waterloo, N. Y.

Mrs. J. W. BACON.

AN OLD BOOK, OR MARCUS AURELIUS AND THE BEES

BY GRACE ALLEN

From the quiet heart of an ancient book

Some old, old thoughts reached out to me;
They gripped like grave eyes with a level look,

While I wandered out to my cherry tree.
And there in the shadow-flecked, white-walled hives,
At peace with the darkness, athrill with the sun,
A myriad bees were living their lives
And winning the peace the old book won.

"Choose ever the best, my Sacred Soul!

Be true to the highest self within!
Be one with the whole, the large, wise whole!
Ah, the poise that a calm content may win!"

Through the swing of a thousand years and more
These thoughts have throbbled at the old book's heart,
And the same mood comes with the murmur and soar
Of the brave bees doing their humble part.

A. I. Root

OUR HOMES

Editor

And these words, which I command thee this day, shall be in thy heart; and thou shalt teach them diligently unto thy children, and shalt talk of them when thou sittest in thy house, and when thou walkest by the way, and when thou liest down, and when thou risest up.—DEUT. 6: 6, 7.

As I start to dictate this Home paper, I realize that a great crisis and responsibility in this month of October is resting on the people of Ohio; and not only of Ohio, but as the people of Ohio shall act and vote in this coming election (November 2) so will, at least to a great extent, the people of other states act and vote. The great and overwhelming victories in South Carolina, over two to one in favor of banishing intoxicants, is, of course, encouraging, and will help greatly the desired outcome of our work here in Ohio. The liquor people are urging that South Carolina is only sparsely settled. It has no great cities like Cleveland, Columbus, and Cincinnati; and they are urging, also, that the rural population has no just right to dictate to the people in the large cities. They are urging, also, that all of the nineteen dry states are *also* sparsely settled, with few large cities. This may, to some extent, be true; but it does not alter the fact that the burdens in the way of taxation rest on the rural people as well as on the cities—perhaps to a greater extent in some ways. They seem to forget, or purposely ignore the facts and figures just coming to light, in the way our penitentiaries and asylums are filled by the victims of the liquor habit. They forget, also, the facts and figures in regard to revenue which have been held up so much, showing that the taxes are lighter in the dry states, especially Kansas, and far lighter in prohibition towns and cities, than in the wet states and wet cities. An examination of the facts we have given you during the last few months will, I am sure, convince any candid reader of the truth of what I have just stated.*

* Since the above was dictated I find a most excellent article in the *Ladies' Home Journal* for September, written by C. R. Stelze. The article is headed: "Suppose all the saloons were closed, what would happen to the saloon-keeper?"

After giving the enormous figures the "wets" claim that would be lost, and the number of people thrown out of employment if prohibition should come, we quote as follows:

The entire argument is based upon the fallacy that, if the *liquor-dealers* fail to get the money now spent for beer and whisky, *nobody else will get it*. It is assumed that, if a man doesn't spend a dollar for "booze," he will throw that dollar into a bottomless pit, instead of using it to purchase some other commodity which will do good instead of harm, which will have a permanent value, and which will give the workmen of the country more work, more wages, and greater prosperity in every way than if the same amount of money were spent for beer and whisky.

This morning I am thinking particularly of our Sunday-schools when compared with our saloons. Saloon-keepers recognize, and always have recognized, the fact that Sunday-schools are one of the worst enemies of their traffic, and in a like manner the Sunday-schools recognize that saloons are their worst enemies; for it is recognized everywhere that the saloon-keepers would do away with Sunday-schools if they could. Not only that, they would do away with Sunday as a whole, if they could. In fact, they trample Sunday and Sunday laws under foot at every opportunity. As an illustration, let me give you a little incident. Some years ago the pastor of our church, a bright educated man—a man, in fact, who stood high before the world in matters of education and Christianity—went to a saloon-keeper in our town of Medina (of course, that was years ago) and in a courteous manner urged the saloon-keeper to comply with the law and close up his place of business on Sunday. What kind of reply do you suppose this good man, who loved God and his fellow-men, received? It was this: "I do not 'go a d—n' on your Sunday," etc. The reply showed his bad grammar as well as his lack of courtesy, and lack of care or regard as to *what* happened just so he got his nickel for drink. Yes, the reply showed, also, a lack of reverence or respect for the laws of man as well as for the laws of God; and that reply shows the lack of reverence for any laws the whole liquor party has shown from that time to this.

Now, please do not understand, dear friends, that I mean the Sunday-schools *hate* or have a *spite* against the saloon-keeper. We are enjoined to love our enemies; and the Sunday-schools, even while they recognize that the *saloons* are their enemies, have no desire to injure the *saloon-keeper* himself—only that they are trying to have him give up his damaging business and engage in something that benefits his fellow-men. While we hate the saloons, we are trying to *help* the saloon-keeper; and we are working hard and earnestly to do away with saloons and not injure the saloon-keeper, nor to fight in malice against him. Let me repeat briefly some circumstances of years ago.

Near the old farm where I was born was a little town, or perhaps I should call it four corners, where was a brewery and two saloons—at least, the two country stores sold beer. Sunday was their great day for

business; and every Sunday night they had what the folks roundabout called the "Dutch dance." The great feature of this dance was beer by the kegful, drunk by boys and girls and men and women. At the time of my conversion, at one of our church conferences I spoke of this plague-spot in our county of Medina, and declared the responsibility rested on our church to start a Sunday-school or some sort of mission work in this little town. There were quite a few smiles, I suppose because of my inexperience, for I was young then, and especially young in Christian work. Somebody suggested that I was probably just the one to open up and carry on a Sunday-school in order to correct or counteract the effect of so much iniquity. I cheerfully accepted the task, and started out. I did not suppose the people roundabout that neighborhood had any idea that I was going to attack the beer business, and I was pretty careful about touching the Sunday traffic or the Sunday dances until I had gotten the school pretty well established. It was a novelty in that region; and not only the children but the parents and grown-up people came from quite a distance around. I taught the little boys and girls to come up on the platform and repeat scripture texts; and the parents were greatly pleased to see their children show off their ability in their childlike ways in this direction. One little chick especially used to please the audience by standing up on the platform by the side of the superintendent while she sang

I am Jesus' little lamb;
Happy all the day I am.

The Sunday-school became such a success that one bright day I shall long remember the seats were all full, and the standing-room was all occupied; and as it was warm weather with the low-down windows clear up, there was a little crowd outside around each window; and you may rest assured that I left for home happy and praising God after the school was over.*

At our prayer-meeting last evening the good pastor said that no great reform was ever started without having its ups and downs. He said that sometimes the reaction is such that things go *away* down, and people lose faith. But he said if the praying men and women just have grace enough to hold on we shall soon find the ups go a little higher, and the downs not quite so low, so that real progress is being made,

* It just occurs to me that one of my plans for getting up enthusiasm in Sunday-school was by offering a pretty little text-card to every boy or girl who would get up before the school and repeat a verse. They would keep these text-cards; and when they had received a certain number the cards were exchanged for a pretty little Sunday-school book.

even at times when we become sadly discouraged. I wonder if this is not going to be true in our work of voting Ohio dry. We had one of the "downs" in our failure a year ago; and if we fail during this coming election we are surely not going down as *deep* as we did a year ago. May God help us; and now let us get back to that Sunday-school not far away from the brewery and saloon.

Sunday, as I have said, was one of the big days for selling beer; and pretty soon the man who owned the brewery began to be suspicious that this popular Sunday-school was drawing away his customers. By and by the attendance, especially among the boys and men, began to fall off; and I well remember one Sunday that, although there was a fair-sized school of girls and women, there were less than half a dozen men and boys present. I made some inquiry as to what was the cause, and one of the women informed me the brewer during the Sunday-school hour was *giving away* beer to our Sunday-school boys, and, as a consequence, my whole school of men and boys were nearly all over at the brewery. I cut short the exercises that day, and with the little prayer in my heart, "Lord, help," I started for the brewery. The boys present, and some of the girls, followed to see what would happen. Before I got there I heard the noise of revelry. I presume I felt something as Moses did when he came down from the mount with the tables of stone and found the people worshipping the golden calf. Somebody looked out of the open door and saw me coming, and out of the open *back* door the whole crowd of boys and some of the men put out on a stampede and hid in some bushes just back of the brewery. I spoke pleasantly to the manager, and asked why the whole crowd of men ran when I came in sight. He said he did not exactly know, but granted me permission to go after them. You will remember the text, "The wicked flee when no man pursueth." It was one of the favorite ones that the little girls used to repeat on that Sunday-school platform. I suppose it was a favorite text because it was short and easily remembered. Well, I went out and found a great part of my Sunday-school in the bushes. Said I, "Why, boys, why should you run when you see *me* coming? You certainly are not afraid of your old teacher, are you?"

They laughed, and hung down their heads, and finally, by a little urging, they came back into the brewery. I asked the brewer to give me permission to talk to them, and I was pretty careful of my

words, you may be sure. I think we sang a hymn they were all familiar with; but it happened so many years ago that I cannot fully remember. I *do* remember, however, asking permission to kneel in prayer; and I prayed most earnestly, not only for all my Sunday-school scholars who were present, but for the brewer himself, his wife, and for his family; and I prayed, too, that, for the *sake* of the wife and family, if for no other reason, the father might be induced to engage in some business that would be beneficial to his fellow-men instead of being harmful. Forty years ago strong drink had not made the havoc here in Ohio that it now has. When winter weather came I told the children there would be a Sunday-school every day all winter. If nobody else came I would be there alone, and there was quite a little rivalry as to who would stand by the teacher. They were, a great part of them, Germans, and they had a German name for a Sunday-school teacher, but I cannot recall it now. I think I said at that conference mentioned (in the foregoing part of this talk) that if a Sunday-school was started and kept up long enough it would do away with the liquor business in Abbeyville, especially if the liquor trade did not hold out the longest and kill the *Sunday-school*; and I never lost faith; but it took *eight long years* to starve out the brewery for lack of patronage. When the brewer quit, the two stores also gave up the traffic; and a good woman who has charge of one of the stores told me a few days ago there had never been, to their knowledge, drink of any kind sold in Abbeyville during the forty years that have gone by; and yet it was all done quietly in the line of "peace on earth and good will to men." I wonder if our Sunday-schools in Ohio are waking up to their privileges and opportunities just now. Are they recognizing the responsibility that rests on them in this crisis?

Some years ago a saloon was started on an island down in the Ohio River. They believed that, by getting off on that island, they would be outside of the pale of the law; and when the place got to be a stench for both Ohio and Kentucky, some good man or woman started a Sunday-school there; and, if I am correctly informed, like the other place mentioned, the Sunday-school came out ahead.

Now, in view of the facts given above and in these pages during the past few months, is it a possible thing that any voter in Ohio, especially one who keeps bees and reads *OLFANINGS*, will vote wet? God forbid. Not only our Sunday-schools but our

churches, our day schools, our high schools and colleges, all places of learning, our physicians (at least the progressive ones), our manufacturers, our railway companies, our penitentiaries, our asylums, our almshouses of every sort, demand a higher order of manhood and womanhood where "safety first" and "safe and sane" are the rule. All of these mentioned above are agreed in regard to the damaging effect of strong drink on humanity—even moderate drinking. Is it a possible thing, dear friends, that the bad people in Ohio, or perhaps I had better say the *bad voters*, shall outnumber the good? If the women, the mothers of our land, could be allowed to vote, there would certainly be no question; and that explains why the liquor party are fighting female suffrage tooth and nail. May God hasten the time when the mothers and fathers shall *all* have a voice in *making* and *enforcing* the laws of Ohio and of the whole United States.

THE RIGHT TO BE BORN SOBER, WITH A SOUND MIND AND A SOUND BODY."

In an address in behalf of good government, delivered at Minneapolis on August 22, ex-Congressman John J. Lentz, of Ohio, put it this way:

"We ought to concede to our babies the right to be born sober, with a sound mind and a sound body, rather than defective because of the alcoholism of their parents. They have the right to be born in an environment that will not deliver them to reform institutions in early manhood and womanhood. We quarantine against cholera and smallpox. Isn't it more important to protect our babies against alcoholism?"

My good friends, is not the above good sound common sense? and will not making Ohio dry in November go a long way toward bringing it about?

STRAWS SHOW WHICH WAY THE WIND BLOWS.

And by the way, friends, there are quite a number of straws floating about that indicate pretty surely the direction of the prevailing wind. Read the following, which I clip from the *Cleveland Plain Dealer*:

VOTES OUT ONLY SALOON; ARCADIA, OHIO VILLAGE, REFUSES TO SANCTION BAR.

FINDLAY, O., Sept. 28.—The only saloon that has been permitted to exist in Hancock County the past seven years was voted out today at Arcadia by a majority of twenty-eight. The saloon was started in that village two weeks ago, and it is said it had a rush trade from Findlay and other near-by dry points.

The saloon would have been voted out the first week of its existence, but the council would not meet to accept the petition of the dries.

You see the people there were humbugged by the "home-rule" proposition; and no doubt that one saloon did a rushing business, as we are told, until public indignation got up to such a point that the

saloon was put down and out in just two weeks; and it would have been put down and out in one week if it had not been for a wet council. Now, here are two important morals pointed out by the above straw. First, here in Ohio, at least, when we find we have made a bad bargain, let us undo that bargain as soon as possible. Second, if we find we have been so stupid as to permit a wet council to rule the town, let us get busy at once and elect dry men for such an important office.

Here is another straw floating in the right direction, which we clip from the *American Issue*:

ASHTABULA DRY AND WET.

During April, 1914, the city of Ashtabula was without saloons. That month there were 28 arrests for drunkenness. April, 1915, was the first month of the Home Rule saloons in Ashtabula, and there were 115 arrests for drunkenness.

When Ashtabula was without saloons the man who was visibly intoxicated was arrested. Now scores of such men are not arrested. The Ashtabula papers say it would be impossible for the police to arrest all the drunken men who are on the streets Saturday evenings.

One Ashtabula merchant says his business has fallen off \$10 a day since saloons are back.

Does it pay?

Still another straw. This one comes from the *New York Evening Journal* for Sept. 27.

This journal claims to be "America's greatest evening newspaper;" and I hope it is true, because of the stand that this daily takes. First they have a picture of a criminal in his cell wearing the stripes, and a bottle of whisky just over his head; and under the picture we find the following:

This picture is published to fix your attention once more on the whisky question as it affects the entire nation, not merely the inhabitants of the prisons.

Why are men allowed to manufacture and sell a drink that every doctor and every sane man recognizes as a poison?

Why is it any more legal to sell whisky to a drunken man than to sell a knife to a maniac or cocaine to a drug fiend?

Whisky has done and is doing a thousand times as much harm as all the drugs put together.

The man who sells a drug to another is put in jail promptly as a criminal, whereas any man can carry on openly, licensed and protected by the state, the business of selling the whisky that manufactures criminals.

By the way, we have one or more daily papers in the city of Chicago that have rejected liquor advertisements and have come out square and bold against the traffic. The above reveals, also, the fact that we have one (God grant that there may be more) in the great city of New York that defies the rum demon. Now, is it not high time that in the great city of Cleveland we have at least one daily on the dry side? When any of our readers find it, will they kindly let me know? It would be too much,

perhaps, to expect that *Cincinnati* should follow suit very soon.

THE NEW DAVIS LAW IN FLORIDA TAKING EFFECT OCT. 1.

Section 4 of this new law reads as follows:

That it shall be unlawful for any person keeping or carrying on, either by himself or another, a place where intoxicating liquors, wines, or beers are sold by retail or wholesale, to employ a minor or a female in his place of business.

We see by the *New Republic* that on Sept. 25 a delegation of 250 girls and women, employed in the liquor business in Jacksonville, called on Superintendent Crooke, of the Anti-saloon League, to see if he could help them. Mr. Crooke called a meeting of the Christian and temperance people of Jacksonville, and made arrangements for a "free employment bureau," to make it their business to find places for the women and girls thrown out of employment by the new law. This was certainly a fine illustration of practical Christianity.

We are told that these women and girls were employed in the wholesale liquor-houses in Jacksonville.

Below is a letter just received from the superintendent of the Florida Anti-saloon League:

Mr. Root:—I am very much pleased to receive a copy of your paper. Though I have never had any dealings with bees, your paper is interesting, and I have been glad to read a number of the editorials written by yourself.

I hope you will soon be in Florida to enjoy the delightful sunshine of our fall and winter months.

I enclose a copy of the Davis law which has just closed up about 200 saloons in Florida; and if the law proves to be constitutional, these saloons will remain closed, leaving only about 75 in Florida.

C. W. CROOKE, State Supt. Anti-saloon League.
Jacksonville, Fla., Oct. 5.

I think I told you that after we failed last winter in getting statewide prohibition the Davis bill was presented and carried as a means of "regulation." Below I give you just *one clause* of said regulation:

SEC. 8. That no gates, doors, windows, or openings of any kind shall connect the place of business of any dealer in intoxicating liquors, wines, or beer with any house or lot so as to permit ingress or egress out of such house or lot from or into such place or business; that no blinds or screens, chairs, settees, benches, or tables shall be set up or used in such place of business; that no musical, vaudeville, or other attractions shall be permitted in such place of business; that no game or games shall be permitted to be carried on in such place of business, nor shall any loitering be allowed therein; that no obscene or sensuous pictures or statuary shall be displayed in any such place of business; that throughout the night a light or lights shall be kept burning in such place of business, and no doors, blinds, curtains, shades, screens, or other things shall be allowed to prevent persons on the outside of such place of business from seeing inside thereof at all hours of the day and night, and it shall be the

duty of the proprietor of such place of business to see that this section is complied with.

No wonder the liquor men have decided that regulation, when it comes to be enacted as above, comes pretty near *annihilation*; and right here is a moral for the people of other states who are considering prohibition. If you fail to get *that*, go with all your might for regulation.

THE OUTCOME OF THE DAVIS LAW IN FLORIDA.

Today is October 9, and we have been receiving day by day cheering news in regard to law enforcement. Below is a sample of it clipped from the *New Republic*:

The Davis act has struck them and their business such a terrific blow that they are perfectly stunned by the force of it; and so hard was the fall that only 23 survive of the 147 dealers of last-year tax.

114 SALOONS CLOSED IN JACKSONVILLE ALONE.

On the morning of October 1 only 23 liquor-houses, wholesale and retail, opened their doors for business, and the sheriff declared that the law was thoroughly enforced throughout the city and county.

Of the former dealers 114 failed to open their doors. At this writing, October 2, nearly all of these have dismantled their barrooms, removed the stock of liquors, and have forever gone out of the liquor traffic.

MAKING A DESERT OF THE GREAT CITY OF CHICAGO.

For some reason, and we hope it is for a good and honest one, the mayor of Chicago declared the law should be enforced, and for once in the world, at least, the saloons should all stop business on Sunday; and on last Sunday, Oct. 3, the edict was pretty well carried out—at least the saloon-keepers made a big protest saying they could never get money enough to pay for their licenses if their best day for traffic were ruled out. On reflection, however, they evidently decided they had given themselves away, and so they turned square about, and declared they would give the good people of Chicago "enough of it." See the following, which we clip from the *Cleveland Plain Dealer*:

WILL MAKE CITY A DESERT: CHICAGO SALOON MEN PROMISE IMPLICIT OBEDIENCE SUNDAY.

CHICAGO, Oct. 7.—The police will have little to do next Sunday in enforcing the saloon-closing order, according to word which came from the liquor interests today.

Word went forth to the 7152 saloonkeepers to "clap the lid on tight" to give Chicagoans a real taste of what the order means.

Plans were begun for a demonstration of the so-called personal-liberty element, probably a parade, Sunday. A parade of the drys, long prepared for, will be held Saturday.

Suppose it should transpire that the people of Chicago, like those over in Russia, should decide in favor of "Chicago dry" every day in the week, then what would happen?

A "TRICK OF THE TRADE."

We clip the following from the *Ohio Farmer*:

A circular is being distributed over the state proposing that pie, cake, tobacco, and picture shows be prohibited. It is not signed, and the "drys" complain that it is the work of the "wets," and that its object is to incite opposition to the pending prohibition movement, its authors expecting that it will be inferred that the "drys" have launched the circular.

The above reminds us of the old fable of the ass that got hold of a lion's skin, and succeeded in frightening everybody for quite a time until somebody noticed the ears of the ass sticking up where the lion's ears should have been, thus showing that the foolish animal was but an ass, no matter what his outward appearance.

SENDING BOOZE TO THE HEATHEN ON THE SAME VESSEL THAT CARRIES MISSIONARIES, ETC.

On page 822 of our issue for Oct. 1 we gave some facts in regard to liquors sent to Africa. Here is something from our friend Minnie J. Ellet, clipped from the *Ohio Messenger*:

I rarely neglect writing down at once anything I hear, or clipping or copying anything I read that shows (or proves) that for every soul we lead to Christ we make *ten drunkards*.

The new Chinese republic, careful to label all poisons, labels the drink we send "The Jesus Poison." American consuls in more than one country forbid the missionaries organizing temperance societies because it equals "boycotting a great American industry."

In spite of protest from thousands of Christians, Elders Wilson and Bryan sent a Chicago brewer to represent us in the Balkan states, and the *Cleveland Plain Dealer* is responsible for the statement that he brags to royalty that the shirt he wears cost twelve dollars. Doubtless the poor fellows who paid for the shirt go shirtless.

All over China agents of distillers, brewers, and cigaret-makers are giving away liberal samples of their goods—creating *appetite*.

I've misplaced an article on "Christian America's Contribution to Darkest Africa." But the contribution of *barrels* in one week runs up in the seventh figure. In three months we unloaded 250 *tons* at one dry port. God forgive America's greed, if he can, but *woe* is pronounced against her.

When coffee was boosted in price, Brazilian planters wondered why Americans should kick when they buy of us beer enough to flood the Amazon River, and it costs them 5 cts. per glass. They think their coffee as valuable in dollars and life-giving properties.

Japanese drink our rum, stagger the streets, or roll in the gutters, saying, "We are Christian."

When America took possession of the Philippines there were fewer than 20 saloons in Manila. Before 12 months had rolled by there were over 300.

GOD'S KINGDOM COMING.

We clip the following from *Farming Business* for Sept. 11:

A PROFITABLE SLUMP.

The Commissioner of Internal Revenue has recently issued a preliminary report for the fiscal year ended June 30, which contains much that is good

news. The national income from the sale of distilled and fermented liquors fell off very materially during the past year. The loss of revenue to the government may seem an unfortunate thing to some people. But the thing which it indicates will be good news of far more import to others.

The ordinary revenue collections on distilled spirits fell off practically seventeen million dollars during the twelve months. During the same time the collections of revenues on fermented liquors was approximately six million five hundred thousand dollars less than the year before. This means that the national consumption of distilled spirits for the year was fifteen million gallons less than for the year before—a decrease of one-eighth. This means that as a nation we consumed only seven-eighths as much spirituous liquors last year as we did the year before.

Would it not be a good thing if we were to keep up that decrease? If we did, at the end of another seven years we would quit consuming spirituous liquors, the greatest destroyer of wealth and personal efficiency—and even of human life—which operates in the world. Some people claim that General Sherman did not say that war was hell; but somebody started the statement, and it is a very true one, as we are learning this year. But all the wars fought in the entire world during the past century have not killed as many human lives or destroyed as much property and wealth as has the use of spirituous liquors during the same length of time. Let us keep on marking off that same internal revenue deficit each year, adding to the national and personal wealth to a far greater degree.

We also clip the following from *Farming Business*:

THE RESULTS OF PROHIBITION.

Prohibition gets results; it actually does prohibit. The best sort of proof a skeptical man could ask for was furnished the other day in the office of the board of tax equalization of Indianapolis. The representatives of the Capital City Brewing Company of that city went before the board and asked that their assessment be materially reduced. In support of their request they claimed that the spread of prohibition during the past few years has greatly reduced the value of brewing stock. The receiver for the company said that he received letters every day from breweries begging him to buy their stock and equipment at 10 cents on the dollar of their normal cost or value.

SOMETHING FURTHER FROM GOVERNOR CAPPER, OF KANSAS.

We clip the following from the *New Republic*:

The state convention of the W. C. T. U. which was held here this year gave Governor Capper the opportunity to say a few good things about prohibition in Kansas that will be heard for miles around outside the boundaries of Kansas.

The Governor has heard from various sources that the liquor interests are busy telling the people who will listen to them that conditions in Kansas under the dry régime are not what they ought to be. That the people are unhappy, taxes are higher, and that the wheat does not grow so fast since the saloons were thrown out of the state.

Governor Capper said:

"Kansas, under the enforcement of her prohibitory law, has made such marvelous advancement in every avenue of progress and well-being that the powerfully entrenched liquor interests, alarmed lest all the states, or the nation, follow its example, have made Kansas the target of their various publicity bureaus. They have covered the entire United States with pamphlets and reports in which statis-

tics are adroitly massed, manufactured, and distorted to prove that Kansas actually is damaged by prohibition, and that there can be no real prosperity, no actual progress without the saloon. One side of their argument is as convincing as the other; but the plausible and apparently conclusive and authoritative array of their alleged statistics puzzles many persons who realize at the same time that they cannot be true or entirely true.

NATIONAL PROHIBITION COMING.

"National prohibition is certain to win. Its complete victory may not come as early as many of us are hoping it will come. But no matter about that. You should keep on fighting. The enemy is strong and resourceful. In a meeting of the National Anti-saloon League two years ago \$30,000, seemingly a generous sum, was subscribed in 30 minutes to fight the liquor power. But the liquor power raised *four million dollars* with which to fight prohibition. This should not discourage us. Neither four million dollars nor four hundred million dollars can stop the onward march of prohibition in this country."

THE METHODIST CHURCH AND THE SALOON TRAFFIC.

The following, also, came to me without any indication as to what paper it was taken from:

Federal action is the only way to curb the liquor traffic, declared Dr. Clarence True Wilson, Kansas man, general secretary of the Temperance Society of the Methodist Church, at the temperance meeting of the conference sessions Saturday night.

"We must have federal prohibition imbedded in the constitution," he said. "Because the alcohol traffic is defended by inter-state commerce and operates under federal protection. The national power that stopped dueling, polygamy, piracy on the high seas, cannibalism on distant islands, unlocked the sealed gates of Japan, uprooted human slavery, drove the lotteries from Louisiana, and their advertisements from the mails, must now be invoked to defend the American home.

Dr. Wilson scored the Home Rule movement, declaring the people of the county and state had a right to determine moral conditions in the cities, and that "the pure stream of country morals and township sentiment was needed to flush out the cesspools of the cities."

The speaker had no patience with the suggestion that the liquor men be compensated for lost property rights.

"No man has a natural, inherent or constitutional right to debauch the American people," he said. He added that there was not money enough invested in the liquor business to pay a millionth part of the bill it owes civilization.

"It is time to serve notice," he concluded, "that no man can be mayor of our city, sheriff of our county, attorney for our district, represent our ward in council, go for us to the state legislature, speak for us in congress, answer for our state in the senate, or get a Christian man's vote for president, if he stands committed to the liquor interests."

Please notice the concluding sentence. If we continue to put men into office, or let them get into office, who are in sympathy with the liquor traffic, how are we going to have law-enforcement?

DON'T BE ENTRAPPED.

Perhaps there is one point the great wide world does not sufficiently recognize. It is this: While the liquor party are ready at

any minute to resort to any kind of trickery or falsehood in order that they may prevent their traffic from being put down and out, the temperance people, representing our churches and schools, and the highest type of truthfulness and honesty in our land, are obviously obliged to be above-board. We are striving to *benefit humanity*, while our opponents care for nothing but their own selfish money interests; therefore it behooves us to be wise as serpents while considering the things before us as people of Ohio. I was reminded of this by reading the following, which I clip from *Successful Farming* for October:

OHIO VOTERS, LOOK OUT!

Beware how you vote on constitutional amendments. Read them carefully and learn what they mean. For instance, the Constitutional Stability League (smooth name!) proposes that the people vote in November on this amendment:

"No amendment of the constitution shall be submitted to the electors which involves any proposal or part of any proposal which since September 4th, 1912, shall have been rejected more than once by the electors, unless six years shall have elapsed since the last rejection."

Do you see the "joker" in that? It is "or part of any proposal." Suppose woman suffrage, prohibition, tax reform, or any other good thing has been twice rejected by the voters. Suppose the enemies of these good things twice propose an amendment which in *part* apparently considers one of these good reforms, but so worded that the voters purposefully defeat it, don't you see that the amendment desired in its *good* form cannot be submitted again for six years because it contains "a part of" a "proposal" that was twice rejected.

This is a trick of the interests that do not want prohibition or woman suffrage in Ohio. You ought to know what to do to any proposed amendment like that of the Constitutional Stability League.

"THE INTERCOLLEGIATE STATESMAN."

The above is the title of a magazine now in its twelfth year. It is published by the Intercollegiate Prohibition Association, Room 303, 189 West Madison Ave., Chicago. Its object is to wake up the students of our colleges to the importance of voting out the liquor-traffic. One might readily suppose that college students would be in *advance* in making our states and nation dry; but instead of that I greatly fear it is true that they are lagging behind in the way of temperance. A few years ago there was considerable said in the papers about banquets held by students of the great eastern colleges—I am not sure whether it was Yale, Harvard, or Princeton. We read in the papers of their banquet and of the quantities of beer they drank; but I had supposed these things were matters of the past. During a very pleasant talk with Mr. Mark R. Shaw, secretary of the association mentioned above, he informed me that such things are still going on; and not only students but some well-known professors are defend-

ing not only the banquets but the beer. If this is true, may God have mercy on us as a people. Mr. Shaw, as an illustration, asked me how I could explain the fact that so many lawyers and doctors are *drinking* men. He said they acquired their drinking habits in the college where they graduated. Just thing of it, friends—fathers and mothers depriving themselves almost of the necessities of life in order to have their boys go to some celebrated college to graduate, and find out afterward that such college taught more iniquity than it did righteousness.

Since the above was in type we find the following in the *Plain Dealer*:

"COLLEGIANS, VOTE DRY." PROHIBITION LEAGUE OFFICER ADDRESSES OBERLIN STUDENTS.

OBERLIN, O., Oct. 6.—"You Ohio college students are going to help us win the state dry this fall," was the enthusiastic statement of David T. Shaw, state secretary of the National Prohibition League, in his address to the students of Oberlin this morning.

He added if Ohio could be aroused to the pitch of enthusiasm attained before some of the big football games of the year a victory for the dry forces would be assured.

ALCOHOL FOR AMMUNITION, TO RUN AUTOMOBILES, ETC.

Even if our good friends of the Cleveland *Plain Dealer* did not show much enthusiasm in announcing that South Carolina had voted dry (more than two to one), it rejoices our heart to find the following at the close of one of their editorials:

Perhaps after all the states have gone dry, and alcohol is no longer used to befuddle the intellect, we shall find that it makes fine ammunition to repel invaders. Or if war shall be abolished simultaneously with drunkenness, the arts of civilization may still be served by this hitherto destructive substance, and we shall know it only as a power to run machines. Alcohol's evil reputation may after all be like the badness of small boys—merely a case of energy wrongly directed.

DRUGSTORES AND WHISKY, ETC.; LONG LIVE DR. WILEY.

We clip the following from the Cleveland *Plain Dealer*:

WILEY REFUSED DRUG-STORE LIQUOR RULE; TRIES TO GET ORDER TO PROHIBIT DEALERS SELLING WHISKY WITHOUT LICENSE.

WASHINGTON, Oct. 6.—Efforts made by Dr. Harvey W. Wiley to get a ruling from federal officials that neither whisky nor brandy may be sold in drugstores after the new United States pharmacopeia goes into effect, today proved unsuccessful.

While the pharmacopeia is recognized as the official list of drugs for the United States, Commissioner of Internal Revenue W. H. Osborn holds that the dropping of whisky and brandy from the list of medicines does not affect the situation with reference to the sales of those intoxicants in drugstores.

At least, the federal government has no interest in that question.

After Dr. Wiley, who is president of the United States Pharmacopeial Convention, read the ruling of the commissioner, he said:

"I am still of the belief that, after the new pharmacopia becomes effective, which will be as soon as the new book is issued some time this winter, no drugstore will have the right to sell either whisky or brandy unless a saloonkeeper's license is taken out and the druggist complies with all the local regulations of the saloonkeeper."

PROHIBITION IN FACTORIES,

We take the two clippings below from *Good Health*, Battle Creek, Mich.:

INCREASED EFFICIENCY IN STEEL WORKERS WHEN SALOONS GO.

Due to the removal of saloons from the city of Coatesville, Pa., accidents in the plant of one of the city's largest steel companies have decreased to the extent of fifty-four per cent in six months.

STOVE EMPLOYEES FORBIDDEN DRINK AT WORK.

The Baker Stove Company, of Belleville, Ill., has issued an order which makes its plant "dry." Hereafter none of its four hundred employees will be allowed to drink intoxicants of any kind while at work. The factory managers are encouraging the men to drink milk instead of beer, and are providing ice with which to keep the milk cool. "We are not posing as prohibitionists," says Mr. George Baker, superintendent of the Baker Stove Company, "but we believe we can increase the efficiency of our men and reduce the number of accidents in the shop if the men are not allowed to drink when at work."

GOOD FOR THE ILLINOIS STEEL COMPANY.

The clipping below was sent us by a friend:

"DID BOOZE EVER DO YOU ANY GOOD?"

"This question," says Dr. W. A. Evans in his "How to Keep Well" department of the *Chicago Tribune*, "is not from a long-haired or even a prohibition orator; it is part of an electric sign displayed over the gates of the Illinois Steel Company.

"It is easy to prove," continues the doctor, "that alcohol harms the ordinary cells of the body. Alcohol is a drug. Alcohol addiction is a drug habit. The abuse of this drug will go the way that drug abuse of every kind is destined to go."

When all the great factories of our land are ready to follow the Illinois Steel Co., booze will have to go.

TEMPERANCE MOTTOES USED AT THE WORLD'S TEMPERANCE SUNDAY AT THE THIRD PRESBYTERIAN CHURCH, TRENTON, N. J.

WHY SALOONS MUST GO:

Because it is the mother of all mischief.
Because it is the chief lawbreaker in the country.
Because it is the enemy of the church and good citizenship.

WHEN?

When we cease to sacrifice our children for revenue.

When Christian men become fully aroused to this evil.

When men vote as they pray.

BY WHOM?

By the prayers and labors of mothers.

By the voters who are determined to care for their sons.

By the officers who are true to their oath of office.

Two hogsheds of beer are equal to one loaf of bread in food value.

Seven millions killed in battle since 500 B. C.; that many killed every year traceable to King Alcohol.

A Titanic of souls lost every day by drink in America.

The saloon will go when Christian men say so.

The mottoes used were taken from a program prepared by Mrs. Stella B. Irvine, 115 Walnut Street, Riverside, Cal.

WHISKY AND BRANDY NOT A MEDICINE; SEE P. 735, SEPT. 1.

We clip the following from the *Pennsylvania Farmer*. After you have read it, see if you cannot join with me in uttering a hearty amen.

The medicinal value of liquor is denied by our most competent medical authorities unaffected by popular opinion. Its value as a revenue-raiser is demonstrated to be a negative quantity. Its only defense is that advanced by the so-called "personal liberty" advocates. To them we would recommend the following plan suggested by a writer in a current magazine. His advice is to married men who cannot do without their drinks. He says, start a saloon in your own home. Be the only customer. You will have no license to pay. Go to your wife and give her two dollars to buy a gallon of whisky—and remember there are sixty-nine drinks in the one gallon. Buy your drinks from no one but your wife, and pay her the regular 15 cents per drink. By the time the first gallon is gone she will have \$8.35 to put in the bank and \$2 to start business again. Should you live ten years, and continue to buy booze from her, and then die with snakes in your boots, she will have money enough to bury you decently, educate your children, buy a house and lot, marry a decent man, and quit thinking about you.

We clip the following, also, from the *Pennsylvania Farmer*. If it does not voice the sentiment of all Christian people, should it not do so? Shall the art of killing people be a part of the education of our youth?

MAKING SOLDIERS OF CHILDREN.

It will be remembered that about twenty years ago there was some agitation in favor of introducing military training into the public schools and other institutions of learning. The idea died "a-bornin'," as it deserved to. It is being revived by some pseudo-patriotic people at the present time. It seems that whenever the air is impregnated with the war spirit some people lose their native good sense. But whatever may be the merits or demerits of the campaign for "preparedness," the proposition to give military training to school children is, in our opinion, foolishness in the extreme. The plea for it on the ground of its value as athletics is far-fetched, as military training is not the kind needed, nor does it serve the purpose of development in the growing youth. More than this, however, when it is stated in plain honest words, military training is for the purpose of producing efficiency in killing and destroying. To be most effective, the spirit as well as physical precision and endurance is necessary. Who will dare put the desire or even the willingness to kill in the heart of a child? Have we forgotten what the great Teacher said—"It were better that a millstone were hanged about his neck and he were drowned in the depths of the sea than that he offend one of these little ones"? Let us hear no more of this talk.

SOMETHING ABOUT THE STEERING-GEAR.

If prohibition should go through, and should prove actually to prohibit, we imagine there would not be anywhere near so many automobile accidents due to the fact that something happened to "the steering-gear."—*Ohio State Journal*.

POULTRY DEPARTMENT

Mankind neither knows of nor enjoys two greater food blessings than fresh eggs and sweet milk.—American Poultry World.

SPINELESS-CACTUS FRUIT; ALSO SPINELESS-CACTUS SLABS AS POULTRY FOOD.

Our good friend G. B. Woodberry, of Glendale, Cal., sends us two fruits, each about the size of a goose egg. I pronounced the quality about like that of a good sweet apple, and, in fact, they are rather too sweet for my taste. I suppose there are other varieties that are more tart; for instance, the fruit of the wild cactus found in Florida is, some of it, quite tart. The sweet fruit might exactly suit some people; and in regard to feeding poultry on cactus leaves or slabs, friend Woodberry sends us a clipping from the *Los Angeles Times*. This gives an account of feeding three different cages of poultry on cactus alone—no water. You see, the idea is, that the cactus supplies sufficient water of itself. You may remember that we have mentioned before that cows and pigs would get along very well without water if they have plenty of cactus. I believe the poultry in the three experiments were confined. Four pullets laid two eggs a day when fed on cactus (12¼ lbs.), and nothing else, for five days. Three sitting hens in store windows, fed only cactus (10¼ lbs.); no water, commenced laying, and gained half a pound in weight. Three pullets in a similar store window began laying, and gained 1¼ lbs. Amount of cactus consumed, 14 lbs. The account of the experiment ends with the following:

Conclusions.—Spineless forage cactus, fed to three sets of chickens for over a week, showed that those laying continued to lay, and those which had been sitting commenced to lay and gained in weight.

While the above was on only a small scale, it demonstrates that poultry can live and do tolerably well on cactus alone and nothing else. Very likely, if the experiment had been continued for a longer period the above might not be as favorable. But if it actually transpires that I can grow cactus in my garden to feed chickens, so as to get eggs without being obliged to purchase any grain at all, it would be a big achievement. If cactus alone will enable the chickens to lay eggs, and increase in weight in confinement, what would it do if the chickens had a range of two or three acres as ours have? Today is Oct. 2, and I am looking forward to the time when I can go back to my Florida garden to raise cactus for my chickens.

SOREHEAD AMONG CHICKENS.

We clip the following from the *Florida Grower*:

I wish to warn the *Grower* family of readers to the danger of "sorehead," and the necessity for preventive measures if they wish to avoid it. Now is the time to commence preventive measures. It will be too late after the trouble is upon you. Begin in July, and feed throughout the summer months the following:

One tablespoonful of sulphur to every twelve or fifteen fowls, mixed with the mash feed once a week. Alternate with epsom salts, same quantity for same number of birds, preferably mixed with a wet mash, so as to insure the birds getting it. It may be given in the drinking-water, but there is always danger of some of the birds refusing it, which is avoided when given in the wet mash. Giving the sulphur, say on Tuesdays and the epsom salts on Fridays, will save untold worry and trouble later on. The late-hatched chicks are the most susceptible to sorehead. By no means overlook them. You will save yourselves a world of trouble, as this disease is especially prevalent here in late summer and early fall; but I have yet to hear of a single case where this treatment was given in advance. Better be safe than sorry.

As a rule I am opposed to giving drugs to chickens; but epsom salts I find recommended by so many of the poultry journals I am forced to believe there is something in it. I suppose the explanation would be that sorehead is caused or at least is predisposed by indigestion; and the epsom salts would prove a sort of physic to cleanse the digestive apparatus. Sulphur is also a recognized anti-fungus. Just consider the results that are obtained by the lime-sulphur spraying used on fruits and vegetables.

COTTON-SEED MEAL FOR POULTRY, ETC.

In testing different fertilizers in our Florida garden we used quite a little cotton-seed meal with good results; and once or twice the chickens got at it and seemed to eat it with avidity. Wesley, however, assured me it would *kill* chickens. He said his former employer lost quite a lot of them by giving them cotton-seed meal; and I have heard from others down in Florida that cotton-seed meal would kill chickens. Later on I noticed that the matter was being discussed in the Florida papers. Some of our experiment stations have taken the matter up; but, as nearly as I can make out, the general conclusion seems to be that cotton-seed meal is a safe and profitable poultry food providing it is mixed with bran, corn meal, or middlings so that it will give not over one-fourth cotton-seed meal in proportion to the other feed. For small chickens I think one-tenth of cotton-seed meal has been recommended.

And, furthermore, as a matter of exceeding great importance, one periodical declares it will take the place of animal food such as ground bone, beef scrap, etc. I am going to make a test of it when I get back to our Florida home. The matter was just brought to mind by the following from the *New South Baker*, sent me by our old friend Henry Borchers, of Laredo, Texas. If oil is a recognized and wholesome article of food made from cotton-seed meal, I do not know why we should not use the meal also for making bread.

COTTON-SEED MEAL IN BREAD.

FORT WORTH, TEXAS.—The latest claim of King Cotton for favor at the hands of his own subjects of the South by home consumption is cotton-seed flour for pastry and bread, which is more properly known as "Allison flour."

G. A. Baumgarten, proprietor of the Schulenburg oil-mills, manufacturer of the flour, went to Houston with a supply of his product and turned it over to the Stude Baking Company for manufacture into bread. Forty loaves were turned out and presented to friends complimentary by Mr. Baumgarten.

The bread contained 20 per cent of Allison flour, made from the choicest upland cotton seed, and 80 per cent wheat flour. The bread was a rich light brown, with a delicious nutty flavor, and, according to Dr. G. S. Fraps, state chemist at College Station, contained as much nutriment as beef or eggs, but 21 times cheaper than eggs, and 15 times cheaper than beef.

P. S. Tilson, of the Houston laboratories, analyzed a sample of the flour and stated that it contained 64.53 protein and fat. Meats contain from 15 to 23 per cent protein, averaging about 17. Patent wheat flour has but 11.73. Cotton-seed flour has been mixed as high as 30 per cent with wheat flour; but 20 per cent is deemed sufficient, and produces the best results, at the same time containing all nutritive requirements.

CHICKENS EATING CROOKED NAILS AND BITS OF WIRE.

I am enclosing a piece of wire, as it appears to be taken from the gizzard of a chicken I dressed. It was sticking clear through the gizzard, and was completely encysted, thus protecting other organs from it. I send it because some time ago A. I. Root in his poultry notes questioned whether chickens would swallow such things. I have found needles and pins in chickens' gizzards, and I think they pick them up and swallow them in their wild hurry to eat all they can, before the others get it.

I now have two chicks that have always been fed alone, and all they can eat; but put them in a barrel of corn chop and they will crowd each other and eat just as fast as they can, as if they thought there was not enough for both.

Doniphan, Mo.

Mrs. J. W. BEAUCHAMP.

I think, my good friend, you have given us the key to this matter. When chickens have plenty of proper food they will be very unlikely to swallow things of this kind that may do them harm; and your letter explains why our chickens down in Florida pay no attention to crooked nails and rusty pieces of wire, and tacks, for our chickens, big and little, always have food where they can get it when they want it. I have ex-

plained before that we put all of our food in galvanized tubs set up on a post where the chickens all know just where to find it whenever they are hungry enough to jump up into the tub. When the chickens are small they have smaller tubs lower down; but just as quick as possible we teach the chickens to hop up high enough so that Florida rats cannot follow them. When they are quite small we are obliged to give them what they will eat up clean, and carefully see that they never get so *hungry* as to swallow rusty nails. Your suggestion about making chickens "greedy" would be a good plan to follow where you want to fatten up young roosters as fast as possible.

THE WET SEASON OF 1915.

Today is October 6, and rain is still coming just a little oftener than we like. We have used the sprinkling system only once, and even then it was a mistake. A shower followed us soon after, so that the sprinkling did harm rather than good. The following clipping from the *Ohio Farmer* not only describes the looks of our Ohio garden, but it portrays also the situation of many other gardens pretty much all over the North. Read the following:

My garden is so full of weeds I can hardly find my "truck," and the "truck" is so nearly drowned out that it isn't worth hunting for. My peas are a big rotten mass of vines, my roots all grow to tops, my tomatoes refuse to ripen, my sweet corn won't ear, and my vines won't set fruit.

This fall or next spring I shall fill all vacancies in my young orchard; but in the meantime I've lost the original price and a year's growth on the trees. I shall set another strawberry patch, of course, but I've lost my next summer's crop. I don't know whether I'll raise much more "truck" or not; two months of rain is slightly dampening to my enthusiasm.

Obviously, I should have raised ducks, water cress, and pond lilies exclusively; but hens seem to stand the deluge as well as anything I am trying. They have dry quarters to stay in at their own discretion; and perhaps if my vegetables could go in out of the rain when their feet get too wet they might thrive better. The production of winter eggs furnished our principal income last year, and the prospect looks much better for eggs this winter so I'm in hopes we won't "sink" entirely; but this is surely a season when a city man would better stick to his job if he has one. He might start a summer resort—he could find a lake and run a boat anywhere—but a dry season next year would be as injurious to his industry as the present one has been to ours.—E. A., Chautauqua Co., N. Y.

THE BOYS' CORN CLUBS.

The average yield of corn in Ohio is 33 bushels. The boys showed that 140 bushels could be grown on one acre. Small youngsters demonstrated that eighty and ninety bushels were easy. Ohio owes a duty to the boys who are willing to make these tests.—*Cleveland Plain Dealer*.

A New Model Typewriter

The No. **9**
OLIVER
The Standard Visible Writer

BUY IT NOW!

Yes, the crowning typewriter triumph is here!

It is just out--and comes years before experts expected it. For makers have striven a life-time to attain this ideal machine. And Oliver has won again, as we scored when we gave the world its first visible writing.

There is truly no other typewriter on earth like this new Oliver "9." Think of touch so light that the tread of a kitten will run the keys!

Caution!

The new-day advances that come alone on this machine are all controlled by Oliver. Even our own previous models—famous in their day—never had the Optional Duplex Shift.

It puts the whole control of 84 letters and characters in the little fingers of the right and left hands. And it lets you write them all with only 28 keys, the least to operate of any standard typewriter made.

Thus writers of all other machines can immediately run the Oliver Number "9" with more speed and greater ease.

Warning!

This brilliant new Oliver comes at the old-time price. It costs no more than lesser makes—now out-of-date when compared with this discovery.

For while the Oliver's splendid new features are costly—we have equalized the added expense to us by simplifying construction.

Resolve right now to see this great achievement before you spend a dollar for any typewriter. If you are using some other make you will want to see how much more this one does.

If you are using an Oliver, it naturally follows that you want the finest model.

17 CENTS A DAY! Remember this brand new Oliver "9" is the greatest value ever given in a typewriter. It has all our previous special inventions—visible writing, automatic spacer, 6½-ounce touch—plus the Optional Duplex Shift, Selective Color Attachment, and all other new new-day features.

Yet we have decided to sell it to everyone everywhere on our famous payment plan—17 cents a day! Now every user can easily afford to have the world's crack visible writer, with the famous PRINTYPE, that writes like print, included FREE if desired.

TODAY---Write for Full Details and be among the first to know about this marvel of writing machines. See why typists, employers, and individuals everywhere are flocking to the Oliver. Just mail a postal at once. No obligation. It's a pleasure for us to tell you about it.

Who Invented the Quadruple Winter Case?

MR. JACOB ALPAUGH, of Stratford, Ontario, Canada, seeing what we had to say on page 697, Sept. 1st issue, about the origin of the new or old method of wintering bees, four in a case, and that we did not know who invented it, writes: "I invented it, and have wintered all my bees in that way for the last 25 years."

Mr. Alpaugh is an all-around genius. He has invented a good many things, and it would not be at all surprising if he were the first to devise this winter-case system of wintering, although the principle of a tenement hive, four colonies to the hive, was used by us 35 years ago.

A Celebrated Bee-rock near Pasadena, California

WHILE in California last winter we were taken on a number of automobile tours among the beekeepers. On one occasion Mr. and Mrs. F. R. Buchanan, of Glendale, Cal., picked us up, together with Mr. and Mrs. Frank McNay, of Pasadena, Cal., and motored over to Griffith's Park, located about six miles from Los Angeles, and about two miles from Lindale. This park contains 3000 acres of land, of mountain scenery, of beautiful drives, and zoological gardens; but what is of more interest to beekeepers is that it has the largest beehive, possibly, in the world, and several beehives. But reference to those will be made at another time.

Mr. Buchanan was very anxious that we should see this rock that is located on an elevation of land that makes it stand out where it commands a view of all the country round about.

No matter at what angle the observer may be located, he will be able to see in the rock all kinds of fantastic shapes—faces of men and animals. The rock has a great many cavities in it, and the arrangement of these cavities in some cases has a sinister look. In these cavities are located colonies

of bees, some of which are probably enormous in size. Apparently no one has ever explored this rock or made any attempt to take the honey, as it is very difficult of access; but bees can be seen flying in at the various apertures in the rock.

We approached it as close as we could, and with our large kodak took a view of it. The result is shown on the front cover page of this issue.

Mr. Buchanan is an old traveling salesman. He made enough money so he has comfortably retired, and he and Mr. McNay are two beekeepers who keep bees for pleasure as well as for profit. At one time Mr. McNay was one of the most extensive beekeepers in Wisconsin. He was once also one of the largest honey-producers in California; but of late years he has taken life easy, as he says, and now plays with his carpenter tools and a single colony of bees. Mr. Buchanan has some thirty or forty colonies; and if there ever was a bee enthusiast in the Golden State, Mr. Buchanan is the man.

In our next issue we shall give a picture of the two men dangerously near the entrance of a beehive.

A List of Government Publications on Bees

THE following letter from Dr. E. F. Phillips will explain itself:

Mr. E. R. Root—You will find enclosed a list of the publications of interest to beekeepers that are for sale by the Superintendent of Documents, Government Printing-office, Washington, D. C. This list will be of interest to beekeepers who do not know just what is available. Copies may be obtained on request to the Superintendent of Documents.

E. F. PHILLIPS,

In Charge Bee Culture Investigations.

Washington, D. C., Oct. 18.

The list of bulletins referred to is as follows:

ANATOMY of the honeybee. 1910. 162 pages, illus. (Entomology Bureau. Technical Series 18.) Paper, 20c.

APICULTURE.

Report of meeting of inspectors of apiaries, San Antonio, Tex., Nov. 12, 1906. 79 pages, 1 plate. Entomology Bulletin 70. Paper, 15c.

- Present status of investigation of bee diseases. (American Association of Beekeepers, New York, 1909.) Paper, 5c.
- of bee-disease inspection in Wisconsin. (Historical notes on apiculture in United States, 1909. Pages 59 to 80. (Entomology Bulletin 75, pt. 6.) Paper, 5c.
- of bee diseases in Massachusetts. 1908. Pages 23 to 32, map. (Entomology Bulletin 75, pt. 3.) Paper, 5c.
- Destruction of germs of infectious bee diseases by heating. 1914. 8 pages. (Agriculture Bulletin 92.) Paper, 5c.
- Historical notes on causes of bee diseases. 1912. 96 pages. (Entomology Bulletin 98.) Paper, 5c.
- Occurrence of bee diseases in United States, preliminary report. 1911. 25 pages. (Entomology Circular 138.) Paper, 5c.
- Relation of etiology [or] cause of bee diseases to treatment. 1908. Pages 33 to 42. (Entomology Circular 138.) Paper, 5c.
- Treatment of bee diseases. 1911. 22 pages, illus. (Farmers' Bulletin 442.) Paper, 5c.
- FOUR BROOD. State and Territorial laws relative to four brood. 1909. Pages 185 to 200. (Entomology Bulletin 61.) Paper, 5c.
- of honey. 1912. 47 pages, illus. (Farmers' Bulletin 503.) Paper, 5c.
- Hawaiian honeys. 1903. 21 pages, illus. (Hawaii Agricultural Experiment Station Bulletin 17.) Paper, 5c.
- Honey and its uses in the home. 1915. 26 pages, illus. (Farmers' Bulletin 653.) Paper, 5c.
- Production and care of extracted honey; Methods of honey-testing for beekeepers. 1907. Pages 1 to 18. (Entomology Bulletin 75, pt. 1.) Paper, 5c.
- of honeybees in Massachusetts. 1909. Pages 81 to 109, illus. (Entomology Bulletin 75, pt. 7.) Paper, 5c.
- POLLEN. Behavior of honeybee in pollen-collecting. 1912. 5 pages. (Entomology Bulletin 121.) Paper, 5c.
- PORTO RICAN BEEKEEPING. 1914. 24 pages, illus. (Porto Rico Agricultural Experiment Station Bulletin 15.) Paper, 5c.
- QUEEN BEES. Rearing of queen-bees. 1905. 32 pages, illus. (Entomology Bulletin 55.) Paper, 5c.
- of bees. 1912. 5 pages. (Entomology Circular 169.) Paper, 5c.
- TEMPERATURE. Temperature of bee colony. 1914. 29 pages, illus. (Agriculture Bulletin 96.) Paper, 5c.
- A study of the effect of temperature on bees. Temperature of honeybee cluster in winter. 1914. 16 pages, illus. (Agriculture Bulletin 93.) Paper, 5c.
- This bulletin presents studies of bees as affected by temperature conditions during winter, and is of special interest to beekeepers in the North.
- WAX-MOTHS and American foul brood. 1907. Pages 19 to 22, illus. (Entomology Bulletin 75, pt. 2.) Paper, 5c.
- WAX-MOTHS. The control of wax-moths of bees. 1911. 16 pages. (Entomology Bulletin 161.) Paper, 5c.

of Agriculture. We have gone over it carefully, and only regret that it could not have been issued in September. As it is, we hasten to place some of the material in it before our readers.

The authors estimate that the beekeepers of the United States lose at least a tenth of their colonies every winter; and that the losses *may* reach a half and sometimes more in some sections. These losses, they believe, could be reduced to less than one per cent.

We hope that they are right; but it is our opinion, based on an observation of thirty years, that, even if their directions are carefully followed, there will be some winters in some localities when the losses will be heavy. However, we are frank to admit that a large percentage of the losses is due to ignorance of the very principles set forth in this bulletin, which principles we believe are correct. We therefore recommend every beekeeper to send at once, either to Dr. E. F. Phillips, Department of Agriculture, Washington, D. C., or his congressman for a copy of Farmers' Bulletin No. 695.

CAUSES OF WINTER LOSSES.

In reference to the causes of winter losses this statement is made:

THE CAUSES OF WINTER LOSS.

The causes of the death of individual bees or of a colony of bees in winter, barring unusual accidents, are only two in number: (1) Inadequate stores and (2) excessive heat production. The numerous factors usually given in the literature on the subject as entirely distinct fall into these two classes, except for some that are usually given which the authors do not believe to be operative.

Doubtless some of the old veterans will take exceptions to this; but if they will study the matter carefully they will see that they are the fundamental causes. Every one will agree that the stores should be adequate in quality and quantity. There can be no controversy about this; but when all the other causes are summed up under the three words "excessive heat production" there will be more or less dissent. Let us see.

Some will say that it is not "excessive heat," but cold that kills the bees; and this cold may be due to continuous severely cold weather or to a lack of packing or insulation. The authors showed last winter by a series of experiments that cold causes excessive heat generation. The effort of the cluster to generate its own heat, which it can do, causes increased activity; activity causes a heavy consumption of stores, and this brings on dysentery. It is seldom that a *good* colony freezes to death by sheer cold. Death is, 99 times out of 100, caused by dysentery as a result of increased activity.

The Fundamental Principles of Good Wintering Outdoors

FARMERS' BULLETIN No. 695, entitled "Outdoor Wintering for Bees," by Dr. E. F. Phillips and G. F. Demuth, has just been sent out by the United States Department

ity. Examination of the hives where bees have died, in 29 cases out of 129, if not 399 out of 1000, shows hives to be soiled by liquid feces.

HEAT GENERATION BY A CLUSTER OF BEES.

While the authors do not make this statement, we believe it to be in harmony with their teachings. In order that the reader may better understand the subject of heat generation, if he has not already read page 789 of our volume for last year, and pages 49 and 93 of this year, we quote all that is said in the bulletin on this subject.

TEMPERATURE OF THE HIVE.

It was first shown by the authors in the bulletin to which reference has been made that at the time of the winter of 1913-14, 57° and 60° F. or around 60° F. is the average of bees when they are clustered in the hives in winter in the north. When the temperature of the air outside the hive falls, the bees raise the temperature of the air inside the hive) falls to 57° F. or lower, they form a cluster, and those in the center begin to exercise their muscular activity, while those in the outer portion serve as insulators by crowding close together, usually with their heads toward the center of the cluster. The innermost portion rapidly acquires a temperature considerably higher than that of the air about the bees before clustering was necessary, often rising to 80° F. In several instances and higher in abnormal ones. The number of bees engaged in heat production increases as the outer temperature falls, and the insulating zone is consequently decreased in thickness, but becomes more compact. The entire cluster becomes smaller as the outer temperature falls.

If bees can be kept in any wintering method, the temperature of the air immediately surrounding them is 57° F. or slightly above, they are saved much unnecessary and unprofitable labor. To the theoretical objection that bees need exercise, it is necessary only to state that the authors have so wintered bees in a cellar as well as outdoors with wonderfully successful results. If bees are kept in a cellar under the best conditions the results are excellent; but it is not proposed to discuss this more complicated phase of the subject here. If wintered outside in a packing-case, with abundant insulation, any heat generated escapes slowly and the temperature of the air in the hive rarely falls below 55° F. If inadequately protected, the temperature of the hive can fall below 50° F. and the bees must generate much more heat. In single-walled hives it is common for the temperature of the air around the cluster to fall to freezing or lower, in which event the bees generate an excessive amount of heat, and perhaps die when they are no longer capable of the necessary muscular activity. The necessity of packing is thus made clear, and in any locality in which the outer temperature often falls to 40° F. or below it is desirable to protect bees to conserve their vitality. If the temperature should fall to 40° F. only a few times during the winter, this would not be serious enough to make insulation necessary. It is obvious, however, that winter protection is beneficial throughout practically the entire United States.

If the reader will please read the foregoing very carefully he will be able better to understand why "excessive heat production" is the direct cause of the death of the bees. Of course it cannot be denied that cold is the real cause of excessive heat production; but cold is already covered up in a new order

usually kills the bees. If the beekeeper can keep the proper temperature in his hives by means of adequate protection, either outdoors or in cellars, there will be no excessive heat generation.

The authors very properly call attention to the importance of young bees in the fall. Old ones soon succumb to the work of heat generation as soon as cold weather comes on.

WEAK COLONIES AND WHY THEY DIE SOON.

Weak colonies cannot stand cold even relatively as well as the strong ones. "Since," say the authors, "the surface of a spherical cluster is proportionate to the square of the diameter, while the volume is proportionate to the cube of the diameter, it follows that a large colony cluster has a relatively smaller surface for radiation of heat than does a small one." It follows, therefore, that the weak cluster must do more work in proportion to its size to keep up the proper temperature, and hence it is plain why they are more inclined to have dysentery than the big colonies.

THE ACCUMULATION OF FECES.

On the question of the effects of the accumulation of feces, the authors say that "Dysentery causes death of bees in winter, so far as has been seen, solely by undue activity and excessive heat production. This detrimental effect is reduced by good stores, but obviously the proper method is to prevent an unnecessary accumulation of feces by preventing a heavy consumption of stores, chiefly by providing a sufficiently high surrounding temperature."

A good queen will better prepare a colony for winter by supplying it with a large force of young bees. She will also furnish plenty of brood in the spring provided the colony is strong enough and the stores good.

METHODS OF PACKING.

On the subject of the conservation of heat and the reduction of expenditure of energy, we feel that we must quote the authors in full; for this question of packing for outdoor wintering is often misunderstood. Here is what they say.

CONSERVATION OF HEAT AND REDUCTION OF EXPENDITURE OF ENERGY.

In outside wintering, the heat produced by the bees is conserved by the insulation of the cluster itself, and also by the insulation of the hive and packing. In the cellar there is less insulation near the cluster, but the cellar itself replaces the packing, and it is in reality simply an insulation. The insulation of the individual hive, of several hives packed together, or of bees in a cellar, serves solely to reduce the loss of heat to the outside air. The amount of heat lost varies with the climate; and it is impossible to make definite general statements in a bulletin intended to apply to all parts of the United States.

general statement which can be made with safety: The majority of beekeepers do not give sufficient insulation, and no beekeeper ever gave a colony too much. For example, in the relatively mild climate of Washington, most beekeepers winter their bees in single-walled hives. The authors have used a large packing-case holding four hives, two facing east and two west, close together. This case was constructed so as to hold 3 inches of packing below, 5 inches on the ends, 6 inches on the sides, and 8 to 12 inches on top. Colonies wintered in such a case in Philadelphia in 1913-14, and in the apiary of the Bureau of Entomology at Drummond, Md., near Washington, in 1914-15, were in much better condition than colonies left unprotected, and cases of this general type are being constructed for the entire apiary at Drummond, except for such colonies as are used in other wintering experiments. The dimensions here stated should by no means be accepted as best for other localities, especially those further north, where the protection should be heavier, but in this particular packing-case the temperature of the air within the hive but outside the cluster usually stood at about 55° to 57° F., except for a reduction in temperature under one condition to be discussed on the next page. The aim of the beekeeper should be to keep the air about the bees at about 57° F., at which temperature there is no condensation of moisture within the hive, even on the inside of the cover, where it first appears. It might be inferred that if double the amount of packing had been used the temperature of the air about the bees would have been too high. This is not the case, for bees cease heat generation when the temperature reaches 57° F. (or even sooner when the surrounding temperature is rising), and the temperature will not exceed 57° F. unless that of the outer air remains higher than that for a considerable period.

Bees well protected and with good stores do not fly from the hive because of the warmth within when the outer air is too cold for them to do so safely. If bees fly at low temperatures (45° to 50° F.), it is an indication that they need a flight because of an accumulation of feces from poor wintering, and does not at all indicate too high an inside temperature because of too much packing. In conclusion, the beekeeper cannot apply too much insulating material to a hive.

It has been found that, even with abundant insulation, the temperature within the hive and outside the cluster is greatly reduced if the packing-case is exposed to wind. During the winter of 1914-15 a record was kept of wind velocity directly over a heavily packed case (with entrances $\frac{3}{8}$ inch by 8 inches), and it was found that a wind with a velocity of 20 miles per hour directly on the case reduces the temperature within the hives practically to that observed in an unprotected hive. The beneficial effects of the insulation were therefore nullified, and the proper temperature within the hive was not regained for several days unless the outer temperature rose considerably. Beekeepers have long emphasized the importance of protection from wind, but the results observed were much more pronounced than was anticipated or than has ever been suspected by practical beekeepers. The ideal toward which the beekeeper should work is to keep his colonies during cold weather absolutely protected from wind, for here again the protection can not be too great. It is entirely erroneous to assume, as some have done, that such protection is not essential in well-packed hives.

There are several types of hives on the market in which the insulation is built in, to be retained throughout the year. There is no objection to the packing in the summer, except that such hives are not convenient for moving and in some other manipulations. Insulation in commercial double-walled

hives is by means of air spaces or insulation, such as sawdust, chaff, broken cork, or shavings. These hives are better for outside wintering than single-walled hives in any part of the United States, but they do not provide adequate insulation at temperatures below about 40° F. Such hives must, of course, be protected from wind, or they are for the time being no better than single-walled hives.

WIND EXPOSURE AND WINDBREAKS.

We wish to call attention to what the authors say in the foregoing on the subject of wind exposure. On this point they are absolutely right. We would prefer to have colonies in single-walled hives with ample windbreaks rather than colonies in hives well packed exposed to a sweep of wind from a mile or more in all directions. We have proved it over and over again, that an apiary on top of a hill, with an exposure on one or more sides, if the winter is severe, will often suffer heavy winter losses when another yard of bees in the same vicinity, well protected from the wind, will come through winter in good condition. But that does not mean that single-walled hives screened from the wind are adequate protection. There should be *both* windbreaks as well as *packing*, or, as the authors put it, insulation.

In the matter of windbreaks, the authors agree with us that a solid windbreak, such as a tight board fence or a house, is not the equal of evergreens or other dense shrubbery.

In the way of insulating materials, the authors recommend sawdust, planer-shavings, or dry leaves, or whatever is handy. Sawdust should not be packed solid; but leaves should be crammed down tight.

BEEES DO NOT SLEEP OR HIBERNATE.

The authors have done considerable work during the last two or three winters. They have shown that bees do not sleep, and that they do not hibernate. When the surrounding atmosphere goes below 57 Fahr., the cluster contracts and activity begins. If the protection is inadequate, the activity will be greater, resulting in more heat generation, a larger consumption of stores, and, finally, dysentery. A colony with dysentery in the month of February, or even in March, in the northern states, is as good as dead in our opinion unless there comes a warm day when bees can have a cleansing flight.

We believe that if the beekeepers of the country will follow the directions given in this bulletin, particularly if they fully grasp underlying principles, they will be able to eliminate a large part of their winter losses. But we doubt if the time will ever come when they can be reduced to one per cent, taking a series of winters covering a period of 25 years.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

P. C. CHADWICK asks, p. 837, whether one of the most important points to be considered in breeding is not disease-resistance. Yes, friend Chadwick, but that takes care of itself, for a colony that yields to disease is not likely to give a big yield. Surely, however, I would not breed from a diseased colony.

A CANADIAN inquirer asks whether I have given in "Fifty Years among the Bees" the way I prevent swarming. I think to no other problem in beekeeping have I given so much thought and effort as to that of prevention of swarming, and the results are given very fully in that book. It gives at least how I try to prevent it, although I do not always succeed.

THE presence of laying workers is not hard to recognize after their brood is sealed; but it is desirable to detect it sooner. The scattering of eggs and unsealed brood is an indication; yet I have known laying workers to fill worker comb just as regularly as the best queen could do it, with one egg in each cell. I think that is likely to be the case when there is little or no drone-comb present. Often the first indication of laying workers is the finding of more than one egg in a queen-cell; yet I have known a good queen to lay more than one egg in a queen-cell in a very few cases. Pollen in a queen-cell is a pretty certain sign—perhaps entirely certain. If you find eggs in drone-cells, especially if more than one egg in a cell, while plenty of worker-cells are unoccupied, you may be sure you have a case of laying workers. The cure? The best cure is to break up the colony.

G. M. DOOLITTLE insists on combs $1\frac{1}{2}$ inches from center to center, p. 796. His good judgment and long experience entitle his views to great consideration. Yet it would cost heavily to depart from the almost universally established $1\frac{3}{8}$, and we should all be willing to concede something for the sake of uniformity. Sometimes, however, the difference is so great that it pays to stand alone; and if Mr. Doolittle thinks so in this case, I respect him for the departure. [This question was argued quite thoroughly twenty years ago. There was a general belief that $1\frac{1}{2}$ is better for store-comb, and $1\frac{1}{4}$ or $1\frac{3}{8}$ for brood-comb. The closer the spacing, the more it discourages the rearing of drone brood. Some even went so far as to argue at the time that $1\frac{1}{4}$ spacing would shut out drone brood

entirely. A great many in England favored $1\frac{1}{2}$ spacing. We know of no one, except for the production of extracted honey, who would space wider than $1\frac{1}{2}$. We decided in our bee-supply department on $1\frac{3}{8}$ as a very nice compromise.—Ed.]

THE EDITOR suggests, p. 790, that, by the newspaper plan of uniting, the bees in the upper hive might smother on a hot day. As a strong colony is not used in uniting, there is little danger; yet it is well to be on the lookout, and so, thanks for the suggestion. [We once placed a comparatively weak colony, that we were treating for foul brood, over a bee-escape board with a Porter bee-escape. The escape was clogged with dead bees, but we did not know it. The day was very hot; and before night the bees smothered, the combs melted down, and the honey ran out between the cracks of the upper and lower stories. Robbing got started, and you'd better believe we had trouble in cleaning that yard of foul brood, and it was two years before we dared to move any bees out of it. For that reason we would feel a little cautious about putting even a weak colony above a newspaper for fear that a hot day might come in October, or several of them, and melt the whole business down.—Ed.]

WESLEY DIBBLE, you say, p. 769, that if you're not mistaken all the introducing-cages require opening the brood-nest for introducing queens and removing cages. In most of my introducing I don't open the hive at all. Without any opening, the cage is thrust into the entrance of the hive, the No. 3 Miller cage being arranged so the bees cannot get at the candy. Two days later the cage is drawn out and the candy exposed. Then the cage can be taken out any time after the queen has left it. [This manner of introducing would be all right with queens bred in the same yard and during warm weather; but in our opinion queens so introduced that have just come out of the mail-bags would not be as readily accepted as the same queens in cages put between the frames of brood near the center of the brood-nest. As a matter of fact, a fresh laying queen can often be let loose into a colony in the same yard just made queenless. The theory seems to be that if the bees do not discover that they are queenless they are not looking for or expecting to find a new laying queen, and the interloper goes on with her egg-laying the same as her predecessor, and the bees apparently none the wiser.—Ed.]

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

Now where should one keep that precious October 1st GLEANINGS—in the regular GLEANINGS file or among the cook-books? They are both clamoring for it. Yes, I know what Solomon said to do to the baby, but I do hate to cut it in

half.

It looks like an early fall here; and if we should have a "regular old-fashioned" cold winter, I fancy it's no more than is due us, as the last two or three have been mild enough. Everybody in this section winters outdoors in single-walled hives, and it will soon be time to look into the question of winter stores.

One day early in October, while we were tramping through the autumn sunshine, in the old deer park of the once famous Belle Meade farm, looking for nuts, we came upon great stretches of white aster and goldenrod. There were plenty of bumblebees and butterflies on them both, but not one honey-bee could we find.

I have read of bees and chickens not living in perfect accord. Our half-grown Rhode Island Red chicks wander around among the hives, snapping flies off the alighting-boards, and never trouble the bees. Nor, apparently, do the bees trouble them. If they are buzzing around too thick, the chick shakes his queer little head, half baby-fuzz and half feathers, and just snaps up another fly. But he makes no mistake about snapping bees. And when, during a recent illness, the water-jars mentioned in a previous page were neglected and allowed to become empty, and the bees, hunting another watering-place, appropriated one of the chickens' drinking-vessels, it was quietly relinquished in their favor. Now they claim it fully as their own.

When I looked into a few hives yesterday I was genuinely dismayed to find a lot of dead brood. There were great patches of sealed brood, with numbers of fully matured bees, heads partly out, dead. I did not have time to go through all the hives nor to examine very thoroughly those I did open, but practically every one of them had more or less of this dead brood. I am at a loss to understand it, unless the suddenly severe weather, that came upon us recently with heavy frosts, chilled it. No signs of

eggs or larvæ either. Brood-rearing evidently stopped almost entirely, if not utterly, for the time, ten days or more ago. But it does seem as though the bees could have kept such mature brood warm. I hope it's nothing worse than the cold weather. Being quite inexperienced in bee diseases I felt at first a wild desire to send immediately for Dr. Ward, our state inspector, for a diagnosis, but refrained for further personal investigation.

FOR BEGINNERS.

As to these winter stores, you want each colony to have from 25 to 30 pounds of honey to winter on. And if it is difficult for you to estimate it, scattered as it is through different combs, just weigh a few colonies until you accustom yourself to the feel of a properly heavy colony. If you have only a few hives, you can easily weigh them all. The hive itself, with bottom-board and cover, and ten combs, will weigh from 25 to 30 pounds (weigh one first yourself, though, and verify—there's nothing so valuable as first-hand knowledge); so with its occupants and the honey for winter you see you should show 55 or 60 pounds on your scales.

The contraption we rigged up when we first wanted to weigh hives was very amateurish; but it did the work and we still have it. We took two stout cords, each long enough to be laid across the top of the hive and reach on each side to the bottom of the bottom-board. To each end we attached a hook that would catch underneath. The two cords are then placed about a foot apart across the hive, so it will balance easily, and the hooks adjusted. Then we slip a strong narrow stick (a short piece sawed from a broom-handle would be good) under the two cords. You see this would make an excellent handle for lifting. The hook of the spring scales is then put under this improvised handle, the whole affair raised clear, and the weight thereof read on the scales.

Another thing: Of course you want to be prepared ahead of time for increase and crops and all that; but don't go putting foundation into a whole lot of frames that you merely *hope* you may use, and then later in the season, with a forlorn hope of getting them drawn, may be stick them in supers on top of some nuclei that won't do anything but gnaw holes in them and leave them dark and stained, and looking as sorry as you will feel.

THE LAMENT OF THE DRONES

BY GRACE ALLEN

No more?

Not ever ever more within the hive
 No more to feel its friendly shelter 'round?
 No more to share its pulsing peace, alive
 With vibrant hum of motion and of sound?
 And we so powerful-winged and light of
 heart!
 Of all this life we love are we a part
 No more?

No more.

Not ever ever more within the hive.
 An unimaginable end has come.
 The things are turning dead that were alive
 And all the singing voices turning dumb
 And life herself, who one time bade us be,
 Has turned away her eyes, which we shall
 see
 No more.

And this the end?
 No end but this for those uncounted days
 Of banquetting, or those mad hours of bliss
 We went careening, careless, through the ways
 Of miracle and light? No end but this?
 No end but this. No proud sustaining thought
 Of deed with rapture or with patience wrought—
 No end but this.

More and more
 The dripping night that stalks without the hive
 Draws round us, dread and ghostly, grim and stark;
 Within, the deepest shadows are alive
 With warmth and fragrance, and the very dark
 Dreams day to come. But though the great sun burns
 A million dawns awake, the day returns
 To us, no more—no more.

The Dixie Bee's source of inspiration.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

No rains of consequence this autumn to date, Oct. 12.

The loquat buds are coming out, and bloom will appear in November, with eucalyptus following closely.

My home demand became so great for good honey that I was obliged to buy that I might take care of local orders. I sold a little too close earlier in the season.

There is said to be a house in the city of Redlands that now holds eight swarms of bees, all of which have entered of their own accord in places of their own selection.

The best honey season for the past fifteen years was in 1905. The first rain that season was on Dec. 31, 1904. This was followed closely by frequent and heavy rains lasting until the first of May.

The "Backlot Buzzer" tells of the troubles of a man who was afraid his bees would get hay fever from working on goldenrod. Come to think of it, I wonder if it could be the bees I found recently under the pepper-trees had sneezed themselves to death.

If all of those recipes for cooking with honey were in the household of every family the results would be good without doubt; but confined to an issue of a bee journal read mostly by beekeepers the results cannot be so widespread. Yet it is a commendable undertaking. If the use of honey for cooking could be put under the fad of style the results would be obtained in a very short time.

The honey season at this date (Oct. 12) may be said to have closed. A few scattering places may be yielding a small amount of nectar, but for the most part we are beginning the consumption of stores rather than the production. Bees in this locality are in excellent condition where sufficient stores have been left for winter. The bluecurl has yielded enough to cause a very healthy brood-rearing condition that has

left a good force of young bees with which to enter the winter months.

The day of automobiles as a necessity is at hand. The time was when they were considered a luxury; but as the age grows faster, more rapid means of transportation is an absolute necessity. A man with several apiaries cannot afford to lose time with the ordinary horse as motive power, if he can get an auto.

Dr. Miller, you ask what I do with old combs in transferring as described on page 616. All of good quality are cut out and sold as bulk comb honey. The old combs I melt up for the wax and honey. The solar extractor is the ideal place, for in that both honey and wax can be saved. The honey comes in handy for feeding purposes.

In a certain warehouse in southern California there is a number of cases of last year's honey. Some of the cases are bulged, and leaking from the pressure of sour honey. It does not pay, boys—it positively does not pay to extract nectar. Ripe *clean* honey is the market-builder, and every one should work to that end. Preach it to your neighbor, and, above all things, don't forget it yourselves.

I will venture the opinion that the late rains leaving the white clover in such excellent condition do not in any manner insure a clover crop next season. I have seen just such seasons in the East myself, only to be followed by a cold and almost snowless winter, with dry April and May. The old Indian was asked how the corn crop was going to be. He replied, "Don't ask me—ask July and August." As to a honey crop from white clover, April and May must be consulted.

Another case of American foul brood has been discovered in my Tremont apiary, just two hive-spaces from where a case was removed last spring. The combs and bees will likely find their way to a bonfire as the cheapest way to get rid of a single case. However, I wish it distinctly understood that I do not recommend this process where there are several cases. I will never be guilty of burning a hive while in my right

mind; and no great number of combs should ever be burned. The bees may be killed and the combs melted up, but it is a willful waste to destroy any quantity of wax in diseased combs.

I have not mentioned the sad accident that befell Mr. J. E. Plesants, bee inspector for Orange County. This venerable gentleman was attacked by a vicious bull, and nearly killed. I understand his wife came to his rescue with a pitchfork, and was obliged to inflict terrible punishment upon the animal before she was able to rescue her husband. At present, I am informed, he is able to be about. A mad bull is a frightful enemy, and dangerous. Some fifteen years ago, while out hunting with a brother-in-law I was followed for nearly a mile by one of these animals, but refused to run. I had the privilege of walking backward with a Winchester rifle within ten feet of his head while my brother-in-law held a shotgun in his face. We escaped, but had that fellow made a mean motion he would have been killed on the spot.

Mr. Raleigh Thompson, page 801, Oct. 1, says he "wants to give Mr. Chadwick something to dream about," and then tells something of his family of six. But really, Mr. Thompson, a family of six is "no dream" with me, but has been a serious reality for a number of years. But, laying jokes aside, his main object was to prove that honey is not a luxury. Well, customs make laws, and it is a very common custom to treat honey as a luxury. It is not considered a staple article of food, and is far too seldom included in the daily order for groceries. I remember, when a boy, of an uncle having given my mother some honey, and there was straightway a childish rejoicing in her household because of that honey. Luxury was the only thought we children could consider on the occasion, and it was surely a luxury to us. Just start out peddling honey, and see if it is not considered a luxury by most people. As long as it is treated as a luxury it will of necessity be a luxury.

I agree with Dr. Miller when he says, "It is a common thing to find pollen on the inside of a comb and young brood on the outside." But when I find such a condition I feel that I should like to have found it a little sooner so I might have placed an empty comb next to the pollen side and had it full of brood on both sides. The bees will remove the pollen as Dr. Miller says,

but they are materially aided by being relieved of the necessity of having to remove it. Mr. Doolittle says, page 750, Sept. 15, "Any comb that is to be put between combs of brood should be full of honey, and that honey preferably sealed." In this I do not agree at all, and I would thank no one for retarding the work of my queens in any such manner. Spreading should never be done unless conditions are such as to induce the queen to fill an inserted comb in twenty-four to forty-eight hours.

The net-weight law seems to be coming to the front as a desirable requirement, and is now being commended fully as much as condemned. Now, if we could get a law to compel the use of excluders we would be assuring the public that they were getting clean honey and not larvæ soup. Wouldn't there be a "howl" then? Eventually, however, the cry would die away, and we would be more sure of the cleanliness of the honey we are using, and the public would get a better article. Like all laws it would not be objected to by those who believe excluders to be a necessity and a convenience, but might work an imaginary hardship on those who are conscientiously trying to produce a clean article without the use of excluders. Some of the latter, I am glad to say, do produce as good an article without as with excluders; but they are losing more honey than the price of excluders would come to each year. A careless beekeeper using no excluders brings about a sorry condition at the honey-house.

Mr. Editor, you say, page 746, Sept. 15, "Practically all honey will granulate if given time enough and subjected to alternate heat and cold." Personally I do not believe that alternate heat and cold has any influence on the granulation of honey. The cold has, and it is the all-important factor. If honey (most honey) is kept at an even warm temperature it will never granulate. If kept at an even cold temperature it will granulate just as quickly as if kept warm and then cold. But some kinds of honey will never granulate, regardless of the temperature or its changes—at least it is not very likely to remain on hand a sufficient length of time to granulate. I have a sample of honey from my 1912 crop that has not shown the least sign of granulation, and I shall keep it as a test to see how long it will remain in the liquid state. Bluecurl honey has about the highest chemical freezing point of any to my knowledge, and it will granulate, apparently, hot or cold.

BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado.

THE LATE SEPTEMBER FLOW.

Bees in western Colorado stored honey well into September, and in some localities supers of comb honey were filled after the 15th of the month. This late flow materially increased the crop upon the western slope. Taken as a whole, western Colorado had a better crop than the eastern part. The crop was good in parts of eastern Colorado and very poor in others.

Prices have been better than for average seasons; and while the shipments have been going out at a good rate, there is not much indication of a weakening of the market.

The prices secured in eastern Colorado have ranged around \$3.00 a case. In western Colorado, where freight rates are higher, \$2.85 is the highest that comb honey has brought, except for a few shipments. Cash is being paid at the car door for many of the western-slope cars that are being shipped this year.

The associations are not permitted to handle honey or produce for non-members; and as few of the associations are owned by the producers, there is not much produce being handled except by purchase. I am informed, however, that the law is being evaded in various ways, so that produce is virtually handled on commission. Honey, however, seems to be in a class by itself, as cash deals are the rule.

The honey-flow in many parts of Colorado was so slow that none but the very strongest colonies stored honey in the comb-honey supers. Medium and weak colonies packed their brood-nests with honey, crowding out the queens so they could do scarcely any laying. This condition is not good for wintering, as there will be a lack of young bees for winter strength. The men who removed two or three combs of honey from the brood-nest, and replaced them with empty comb, will profit by it this year if it was done early enough.

When finishing packing my comb honey the thought came to weigh each section in a number of cases to see how much above or

below the minimum we were running. One case of each grade will suffice to report upon as representative. The case of fancy honey averaged 147 $\frac{3}{8}$ ounces, or 13 $\frac{7}{8}$ oz. net weight, and it was stamped "minimum net weight not less than 12 $\frac{1}{2}$ oz." The heaviest section weighed 15 $\frac{1}{2}$ oz. net, and the lightest (and only one of them) 12 $\frac{1}{2}$ oz. The case of honey weighed 33 oz. more than the minimum weight called for.

The selling price of fancy comb honey, we will say, is \$3.15 a case. This would average 15 1-6 cents a pound for the honey. If I had given no more than the weight stamped it would have averaged me 16 4-5 cents per pound. Perhaps I am losing money by not stamping the weight nearer what it actually is; but there does not seem to be a great deal of trouble in selling honey when stamped as we are doing.

The No. 1 case is somewhat heavier than the average of this grade. The lightest section weighed 13 $\frac{1}{2}$ oz., and the heaviest 16 $\frac{1}{2}$, and the average weight was 14 $\frac{1}{2}$ oz. with a little over. Three and three-fourths pounds above the minimum stamped was given with this case. The selling price of this grade is placed at \$3.00 a case, which returns 14 $\frac{1}{2}$ cents for the honey actually given; while if no more than the minimum net weight were given the price would be 18 cents a pound.

The No. 2 case weighed 319 $\frac{1}{2}$ ounces—an average of 13 $\frac{3}{4}$ or 3 $\frac{1}{2}$ pounds above the minimum requirements. If the minimum amount of honey had been given in this case, and the price of \$2.85 secured (which is the going price here), the honey would average 17 3-11 cents per pound. The actual honey given averaged 15 3-5 cts. per pound. This honey stamped "net weight not less than ten ounces" brought more money per pound than the other two grades, as you can see by referring back.

The lightest section in this case weighed 11 ounces net, and the heaviest 13 $\frac{3}{4}$.

The question is, "How much more could be secured for this comb honey if the sections did not vary more than one ounce in any one case?" Such a pack would comply with the demand for closer uniformity; and while it would necessitate some more work in packing, it would not be a serious matter.

NOTES FROM CANADA

J. L. Byer, Markham, Ontario

Brood-rearing was very heavy until quite late in the season, and colonies are going into winter quarters with great clusters of what must be mostly young bees hatched in August and September—in fact, many colonies now in

October still have quite a lot of sealed brood. Other conditions being equal, this should mean good wintering and early building up in the spring. Abundance of clover, abundance of young bees, and abundance of good stores in the hives—are we downhearted? No.

"Prices are running anywhere from 15 to 20 per cent lower than last year on all grades of extracted"—editorial, page 784. As mentioned in my notes for Oct. 1, I am glad to say that such is not the case here in Ontario, even if our country is engaged in the great war now in progress. Never before have we had such a keen demand for honey, and this notwithstanding the fact that the wholesalers have handled very little of our product. At least one prominent dealer remarked early in the season that this year "The beekeepers could carry their own stock, and they would buy from them as they need honey." If others have had the same experience we have had, carrying the stock has not been a very long or trying job, and the wholesalers will not have very much honey to handle.

October to date (11) has been cooler than usual, even if we did anticipate a warm fall after so much cool summer weather. Feeding has been a rather slow job, and once again the inverted pail has proven to be the very best feeder for cool weather, as bees would take the feed in this way when they would not touch it in the old-style feeders. We have just finished feeding, and, all told, have used quite a lot of sugar in the different apiaries. At the north yard, which will again winter mainly on aster honey, all the colonies were fed and packed away for winter by Oct. 9, and they can now run their own show for about six months. During that period I am not likely to see the yard more than once; but I suspect they get along just as well as or better than the apiaries do around home that I do more meddling with during these months. Early packing and a dry warm

location may help to explain how our bees wintered so well on aster honey last year, and with this thought in view the same course was followed this fall again. This is not saying that they will winter well on these stores again this winter, but naturally I have not nearly the misgivings on that score that I had a year ago.

Much has been said about the quality of aster stores for table use, and the surplus I obtained this year is much better than I had last season. In fact, I have sold it locally at the yard for the same price as the clover, and in a wholesale way was also able to get a good price. Color was about as good as clover, flavor very good, but body not as heavy as standard, this usually being the case with all late fall honey, I believe.

That special number of GLEANINGS given over to the uses of honey in cooking is timely, and I hope that many will try some of the recipes given. It is a fact that even among beekeepers there is little known, or at least practiced, in the matter of using honey in domestic baking and cooking. That honey is a fine thing for baking various kinds of biscuits and cakes is a fact attested by the large manufacturers of biscuits who use carloads annually. Honey is dearer than sugar, and we may be sure that these manufacturers would not use honey if they could get something "just as good" for less money. I am well acquainted with the manager of one of the largest biscuit concerns in Canada, and he tells me that they simply have to use honey to get goods that will stand keeping for any length of time without drying out badly, as all biscuits, sweetened with sugar alone, will do. Before honey started to get to the wholesale prices that have ruled here in Ontario for the past few years, we used to sell the bulk of our clover honey to the manufacturers; but of late years they use the cheaper honey which mainly comes from Jamaica and is laid down here cheaper than we can compete with. All things considered, this changed condition of affairs has not hurt us much, if any, in the matter of selling our white honey, as the consumption of this has wonderfully increased during the last three or four years, and many families now use from 50 to 200 pounds of honey annually that formerly used little if any.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

FOUNDATION, A CONVENIENCE OR A PROFIT?

"The older writers often speak of comb foundation, but don't tell us whether you use it as a convenience or for the profit coming from its use. Is there enough in either to pay fully for its cost and the labor of putting it in frames and sections?"

The question of the use of foundation is one that is vitally connected with that of wax secretion. Ever since the general introduction of foundation I have had more or less to do with it. At first there was a decided opposition to its use, both on the ground of the suspicion it would create, even though used in the brood-chambers only, and because of the tough bases of that first made, when used in sections for the storing of comb honey. I entertained many doubts about the advisability of using it in sections, and it was a good many years before I could make up my mind that I wanted to use it in that way, preferring to stick to the old method of using natural-comb starters. Then I used it in very narrow starters, and later on in full sheets in the sections, and finally had most of the brood-combs built on it.

I made an observation hive which was so arranged that I could use one, two, or three frames. With this hive I could watch the development of the foundation into comb after a sheet was put in. Foundation accomplishes two things in a very satisfactory manner when carefully used. In the brood-chamber, all worker and straight combs can be obtained. In the sections it can be used as starters, or the section filled so nearly full that the bees will attach the combs more nearly all around than is generally the case where starters of natural combs are used, while it is much more convenient.

In my study of this matter I find that there are times when more than a starter in the sections is practically a waste of the wax contained in the foundation; for, in many instances, the bees simply add their own wax to the imprint for the cells, not even touching the foundation by way of thinning the base or rudimentary cells. With a copious flow of nectar, such as we often have during our basswood bloom, the wax-producing bees are so loaded with their own secretion of wax, that, with no comb to build, they will use this wax in the place of propolis for the filling of cracks and "plastering" up about the hive. At such

times they will apparently do better work in the sections where only starters are used, and give far more brittle and enjoyable comb for eating. But the very quality that makes it less edible is an improvement on its shipping quality, so that the combs in sections, built on full sheets of foundation, will go some distance in perfect order; while in the same shipment, sections having only natural comb containing the honey in them will become sadly broken in transit.

Do not misunderstand me. The product, where sections are filled with full sheets of foundation, even where the bees simply add their own wax to it without any drawing out or thinning, is less edible only on account of a somewhat increased toughness and amount of wax, as the taste is in no way impaired. The amount of thinning depends very much upon conditions. The temperature, needs of comb at the time, whether urgent or not, the amount of wax being secreted, and perhaps other minor points, all have to do with the matter. I hold to the opinion that wax is secreted more or less freely at all times during a flow of nectar, the quantity varying as influenced by the prospect of its need, the presence and number of bees of a proper age, and the state of the flow of nectar. If it is true that wax is usually secreted in sufficient quantities to hold the honey gathered, the use of full sheets in sections cannot pay, viewed from the point of saving of honey consumption in wax secretion. But from the viewpoint of having the combs more perfectly attached to the sections all around, giving a greater freedom from breakage in shipping, foundation becomes of value in marketing honey in distant cities that would not be considered when our section honey was wholly disposed of locally.

Some advocate using foundation in full sheets in the sections to avoid having drone comb, as worker comb gives a nicer finish when capped over. Years ago, before the advent of foundation, drone comb was greatly admired, as it gave a little glimpse of the quality of the honey contained in the combs. With worker comb capped by black bees, a box of buckwheat honey could not be easily told from one of clover. But with drone comb, the thin capping next the cell walls would tell the color of the honey in the combs in the whole box.

There are few successful apiarists who do not think that it pays to use full sheets of foundation in frames and sections.

GENERAL CORRESPONDENCE

HOW TO PRODUCE NON-SEPARATED HONEY

BY ALLEN LATHAM

It is unquestionably easier to produce a fine article with separators than without them; but when the proper precautions are followed, it is not difficult to produce a good marketable product without separators. This article will be devoted to a description of the method I follow.

Several things are absolutely essential to success in producing non-separated comb honey, and perhaps the first of these is the proper setting of the hive. Hives must be absolutely level from side to side, and preferably level from front to back. The last statement is made on the assumption that the sections run parallel to the sides of the hive.

Unless the hive is level from side to side the combs in the sections will certainly swing to one side, and every section in the super will be imperfect. If not level from back to front there is a tendency to the more perfect finishing of one end of the section. Bees naturally build downward; and if downward is toward one corner rather than the bottom of a section, one corner

will get finished before the other. In hot weather, too, the foundation will be apt to buckle or sag toward the lower end of the section.

I realize the set determination of most beekeepers to slant their hives from front to back. Their purpose is good, but their execution is poor. The hive should be level. The bottom-board should furnish the slant. Every argument is in favor of the slanting bottom-board. One great advantage of the slanting bottom-board is that the bees have depth beneath the combs at the front, and only a bee-space at the back of the hive. This largely prevents the building of combs beneath the frames. My readers who use that style of bottom-board with two sides, summer and winter sides, will appreciate this. The back half of the hive will frequently be stuffed with drone comb between the bottom-bars of the frame and the floor of the hive. This difficulty and others are overcome by a bottom-board which has a slanting bottom.

Next in importance is a big force of bees.

A small colony of bees will produce good section honey when separators are used, for they cannot build comb beyond the separator, and so each section has its own comb limit. When separators are not used, the bees of a small colony will start on a few sections and will work along building each comb into the space of the next section. Hence each section is bulged. Unless one has mastered the problem of keeping his colonies strong he had better not try to produce honey without separators; or shall I say he had better not try to produce honey at all? When strong, a colony (as soon as the flow starts in) will occupy almost the entire super

I detest section-holders, and use free slats 17 inches in length.

A super just as it came from the hive. Note how little bulging.

at once, and will start every section before any are much advanced. As the work progresses with uniform speed in the several sections, the comb of each has its allotted space, and there is little or no bulging.

Next in importance is the strain of bees. It is almost impossible to produce good section honey with some strains of bees; and, though this peculiarity is not limited to honey-production without separators, it is essential to success in such honey-production. One should not breed from such queens as give bees which do not yield well-finished sections. I do not know why it is; but some bees will not build straight combs, even in natural-comb building. They seem to like curves, and will frill their combs. I think every observer will agree with me in this, just as we all know how some strains will persist in building brace-combs, fastening their combs to the separators, or to the sides of the super, or to each other. Breed entirely from queens whose progeny yield a smooth comb with well-developed sides or edges.

Next in importance we might name the method of using foundation. One can produce almost equally good non-separated honey with either starters or full sheets. For over ten years I produced comb honey without separators, using only starters. I gave up starters because I fully believe that one can get a larger crop by the use of full sheets, and also because when starters are used much drone comb is built and the

queen is very likely to enter the super—always with disastrous results. Section honey with drone comb is, at the best, not so pleasing in appearance to my eye as worker comb. So, if one produces section honey without the use of separators he had better use full sheets of foundation.

Now comes the question of using free hanging sheets and bottom-starters, or of using pieces which fill the section from side to side, and do without bottom-starters. I have tried both methods, and can see nothing but wasted labor in the use of bottom-starters. I will not breed from a queen whose bees will not build comb to the bottom of the section. With the right strain of bees there will be absolutely no need of bottom starters. But there is absolute need of sheets of foundation which fill the section from side to side, or end to end.

I buy foundation which is just four inches wide. I cut it so that there will be a scant quarter-inch space at the bottom of the section—that is, I cut it a trifle longer than $3\frac{3}{4}$ inches. I find that if it is cut longer than this it will sometimes stretch so much in hot weather that it will buckle and cause a bulge. Yet I have produced good sections by using sheets four by four, completely filling the section.

The use of hot-plate machines has been dropped. My sections are all filled by the melted-wax system. Blocks of the right thickness are nailed to a light board, and sections placed on these blocks. The brush from the melted wax is run along each end of the section, and then along the top. I make no effort to see that the foundation is attached throughout the side edges, nor even at the top. If four-fifths of the top and half the sides are attached good results will be assured. The sheet must be exactly in the middle of the section, and the section must be square. When the sections are placed in the super they must not be forced to cause the foundation to buckle or spring away from the walls of the section.

It sounds like a lot of labor to put in foundation this way, but it is labor that pays. I can hire a skillful boy at one dollar or so per day, and he can put up one thousand a day. Under pressure I can myself do about two thousand. After one is used to the work he can do it well and expeditiously. It is essential, however, that the foundation be well made, cut true, and that it has not suffered in shipment. It is an art to make foundation, and it is another art to cut the little sheets for the sections. I do not trust the cutting to any one but myself. I can cut five pounds in about half an hour.

Next in importance is the section. Though good results can be obtained with two-bee-way sections, I have adopted almost exclusively the four-beeway section. The passageways at the ends of the sections appear to aid the bees in building the combs true. In their desire to keep open that passage they refrain from building the comb of either section so that it trespasses upon the passage. When sections with two beeways are used, there are often sections which have the combs of one built slightly into the other adjacent section. When taken apart these sections will be dauby. It is less pleasant to handle four-beeway sections; but after one is used to them he forgets all that. Habit should never be allowed to stand in the way of the adoption of an improvement.

The illustration will show more of my method. I detest section-holders. I use free slats just seventeen inches in length, and my supers are seventeen inches in length inside measure. The bee-space is at the bottom, and the sections are flush with the top of the super. My supers are very light and simple; and as I use outside rims, they are amply protected from the weather. The illustration shows a super with top view and with bottom view, just as it came from the hive. One illustration shows the sections removed and piled to display each. These thirty-six sections shown are the original thirty-six of the super. Their net weights are as follows: One weighed 12 ounces; five weighed 12 1-5 ounces; three weighed 12 1/4 ounces; two weighed 12 1-3 ounces; nine weighed 12 1/2 ounces, seven weighed 12 3/4 ounces, three weighed 13 ounces, two weighed 13 1/4 ounces, and four weighed 13 1/2 ounces. It will be noted that the lightest had 12 ounces of honey, and the heaviest 13 1/2 ounces—a range of 1 1/2 ounces. It should be noted here that sections 1 1/2 inches wide are used, designed to produce a twelve-ounce section. The variation in weight of sections was largely due to the more com-

plete filling of some over others. Some combs were doubtless slightly thicker than others, but not noticeably.

One should study the illustration which shows the supers standing on end with a background of white cloth. If the number of spaces be noted where the cloth can be freely seen though the spaces between the combs, it will be readily seen how little bulging there is. It was impossible to show with the camera all the spaces, but every space was clear. Of course, this was a selected super; but I spent some time before I decided which of several supers to put before the camera.

You can lead a horse to water, but you cannot make him drink. I do not expect to win many over to the production of comb honey without the use of separators; but I have led the way. We are all free to do as we please; but when one produces almost exclusively non-separated honey, it shows that it is not a method to be easily cast aside. My crop this year, with more to hear from, is over 5000 sections, and bee-keeping is my avocation. Those who are so strongly opposed to this method of producing honey might do well to learn how it can be done before they condemn it.

It would not be wise to leave one of the illustrations without a word of explanation. In that the super emptied of its contents is shown, and several separators of the fence

The net weight varied but 1 1/2 ounces.

type appear. Though I have very little use for the fence separators as such, I have a high appreciation of their value as followers. A blanket of bees over the outside rows of sections guarantees completed sections where so many fail to get good results. I have more than once, since I adopted this system, seen sections completed and sealed in the outside rows before

those in the center were completed. I would most earnestly recommend all producers of comb honey to use fences between the sections and the super walls. I use by preference fences one side of which have half a bee-space and the other about $\frac{3}{8}$ inch. Those in the illustration are some made over regulars.

Norwichtown, Ct.

WHAT AILED THE BEES?

BY J. W. ADMIRE

The illustration shows a full set of frames taken from an eight-frame hive belonging to a friend of mine. Now nearly 70 years old, he has kept bees nearly all his life. His colonies have ranged in number from one to probably twenty-five.

One day early last spring he stopped me

on the street and said that nine colonies out of twelve had died out, and he thought they must have "winter-killed," as they were wintered out of doors, but that on examination he found that all nine hives contained quite a bit of honey. We went to the barn where he had stacked the hives up with

I never saw a worse case of American foul brood.

contents. As soon as we entered the barn I noticed a strong scent, and I almost knew before opening a hive that his bees had foul brood.

We looked through the hives, and all were in about the same condition. The investigation showed that his colonies had had American foul brood, the worst kind, and he did not know it. I began to question him, and was astonished to learn that he

never lifted a frame out of a hive to inspect it, and had never seen any disease. I found it hard to convince him that his bees had died from foul brood.

I had never seen a worse case. I photographed the contents of a hive. What impressed me more than anything else was to think that a man could keep bees all his life and yet know so little about them.

Hiawatha, Kan.

ACHORD'S SUCCESS IN SHIPPING BEES IN POUND PACKAGES

BY E. R. ROOT

On page 744 of *GLEANINGS* for Sept. 15 I referred to the success of W. D. Achord, of Fitzpatrick, Ala., in shipping bees in pound packages to points in Canada. He has apparently been more successful than most of us, from the fact that he used a larger cage with more wire cloth. In fact, his cage has two or three times the ventilation of the regular standard cages for holding the same number of bees. This extra ventilation and larger cubic capacity has enabled Mr. Achord during all kinds of weather, hot and cold, to achieve almost perfect success.

As stated in our issue mentioned above, one beekeeper in Canada has come to believe he can buy pound packages of bees from the South as cheaply as he can winter over colonies in the rigorous climate of Canada.

Mr. Achord's pound packages of bees are made up of *young bees* ready for business, while the wintered-over colonies, even though of two or three times the numerical strength, are made up of *old bees*; and it would not be very long after the first flight for pollen and water before the wintered-over colony would be but little stronger than the pound of bees, with the disadvantage that most of their numbers would be bees of the previous fall.

To test out the Achord plan of shipping bees we sent an order to the Fitzpatrick

man for two one-pound packages of bees. These were shipped on Sept. 20. They arrived promptly at Medina, and we kept them for a day. There was scarcely a dozen dead bees in the two packages. We then sent them to Dr. E. F. Phillips, of Washington, with instructions to return them to Medina. He reported that they arrived in

W. D. Achord's cages have two or three times the ventilation of the regular cages for holding the same number of bees.

fine condition, with scarcely any more dead bees than when they reached Medina. They were so fresh and nice that we first thought Mr. Achord had sent us a duplicate shipment, because it did not seem possible that those same bees could make three trips and look as nice as these did; but as events showed they were the same bees that left Alabama on the 20th. We kept them for

three or four days in order to watch them; and before we knew it some of the bees in one of the cages began dying. Examination showed that neither package had a particle of food. We immediately replenished the pans with candy; but it was evident that the bees of one of the packages had suffered considerably. However, we sent them on again to Washington, with instructions to return again. This morning, Oct. 7, they came back, and the one that had not suffered from starvation had suffered a loss of only about 150 bees out of a total number of 5000, or a loss of only 3 per cent, after the five trips of 27 days from Fitzpatrick, Ala., and then on to Washington and back, of two round trips.

The bees in this package are still sweet and nice, and possibly would stand more journeys; but 27 days from the time of shipment is as long a time as any bees would be *en route* in the United States by three times over. It may be reasonably

presumed that Mr. Achord can ship bees anywhere in the United States and most places in Canada.

A closer examination shows why the bees in one of the packages used more food than the other. Its bees had built a piece of comb about as large as the palm of one's hand. This occasioned an additional consumption of stores, and incidentally goes to show that bees can build comb without any other food than pulverized cane sugar and honey. Neither cage contained any water. When proper provision is made for ventilation, water seems to be unnecessary.

The cut shows that Mr. Achord has so designed his package that it is impossible to pile any other stuff on top of it, nor anything near it to shut off ventilation. This is quite important. As the express charges are based on *weight* and not on *room taken* in the express car, the projecting sticks add nothing to the cost of transportation.

THE CYCLONE SYSTEM OF BEEKEEPING

BY DANIEL DANIELSON

Many times I have seen pictures of apiaries with straight rows of hives. Of course it looks ideal. I used to have bees in two long straight rows with a car-track between them to carry the supplies out and the honey in; but I have now given up the idea, and have what I call the Cyclone yards. If you look at the hives from an elevated position they look as if a cyclone had dropped them in every way. The entrances face all the points of the compass.

I now have only about two per cent of queenless colonies in the spring, whereas before I had as many as twelve per cent. I run my apiary mostly for extracted honey; and by working the queens for all they can do, I raise the brood above the queen-excluders, thereby preventing swarming, and get very strong colonies to store honey. The queens get a set of empty combs or foundation below whenever the lower story is full of

brood. By that plan the bees usually supersede their queens in August or September.

With the hives in straight rows, and the entrances all one way, a good number of

With the hives in irregular rows, only two per cent of the queens are lost.

the queens lose their way. Since I have the cyclone style of beeyards, very few are missing in the spring. In the winter I put the hives together in a close row, and cover

them with tar paper to protect them. In the spring the hives are put all around, cyclone style, again.

My way of wintering bees for many years has been by using sealed covers. It is the only natural way, the way that God or Nature taught the bees to prepare for winter. If it had been better any other way

the bees would be carrying all kinds of material into their hives to make a cushion on top of the brood-nest.

I am satisfied there is no better way than to let the bees seal everything up tight for winter. Any colony that is strong and in normal condition will come out all right.

La Feria, Tex.

NOTES FROM THE APIARY; NEW APPLIANCE FOR UNCAPPING

BY JOSEPH GRAY

After a season's use of a butcher-saw, weight 3 pounds and length 30 inches, I have no hesitation in recommending it for uncapping. It does away with the need and expense of a fire and the attending danger. It makes a clean cold cut, and is instantly ready for use. A few changes are necessary in the equipment. For instance, you need to be back from the screen 30 inches to allow for the sweep of the saw; and the rest for the comb must not be above 33 inches high. This allows you to stand well over your work. I space my combs wide and obtain combs weighing 7 to 10 pounds. A frame with a 1 1-16-inch top-bar and $\frac{3}{4}$ -inch bottom-bar is ideal. The Hoffman side-bar makes no difference.

Grasping the comb by the bottom-bar, set the lug in the rest and make a clean sawcut from one end of the frame to the other. Reverse the frame so that you always cut from top-bar to bottom-bar. A butcher-knife with a 6-inch blade is a handy tool to scrape top and bottom bar, and also to scrape the capping off. Do not cut those that sink below the sweep of the saw-blade. Scrape them.

In using the saw, just saw as a butcher does. Awkward? Sure you will be so, and very slow at first. You cannot so easily unlearn the upward cut and use of the uncapping-knife and relearn in a day the use of a heavy saw. It takes a butcher years to become expert in its use. When you see the nice even combs that now weigh 6 pounds, and realize how easy and uniform they are to extract, and how regular the bees build these same combs after they have been worked over once, you will see the advantage of cutting off 3 pounds of weight in the capping and throwing out with the extractor 4 1/2 pounds weight, leaving 1 1/2 pounds weight of empty comb, all uniform and all equal.

NEW WAY TO USE THE SOLAR EXTRACTOR.

After my cappings are drained, and the honey piped away to the main tank, I grasp the four corners of a piece of burlap, which

has previously been laid in the bottom of the uncapping-tank, and carry the whole of the cappings to the solar. The arrange-

ment in the solar consists of a removable tin end and canvas. The tin end is cut from the ever useful five-gallon can as shown. The square of canvas is then over the tin, and the capping dumped on to the canvas.

The melting honey and wax flows to the edge and then over into the mold. The refuse is held by the canvas and the edge of tin. The mold is made from a lubricating five-gallon can, side cut out as shown in the illustration, and the spout turned up to allow the honey to escape after reaching a certain point. The honey is not subject to further heat, as it runs under a covered part of the solar to be drawn off later at the faucet. The mold, catch tin, and canvas should be in duplicate to allow the solar to be attended to at night, the wax to cool, and the canvas to be cleaned during the heat of the day.

In case of remelting cakes of wax, use an ordinary five-gallon can. Cut below the

line of the screw top, and press the sides and ends concave so that there will be no difficulty in removing the big cake of wax.

The thin tin of the can yields easily, and only the bottom is held. Load the solar with 24 pounds of wax to remelt, and you

will be able (in this way) to take off a cake of beautiful wax 22 pounds in weight.

SKELETON BARROW.

The Outlaw had a dig at the antiquated method of Alexander's comb-bucket. I suppose our skeleton barrow and long box holding 40 combs would please him. It is built of 2 x 3-inch material, and is 6 inches long—a skeleton or frame only. On this the box rests as shown in cut. The box has a zinc bottom and measures 5 inches long, wide enough for the frame to hang. Four wet sacks complete the best arrangement I have ever used.

Heber, Cal.

THE STRENUOUS BUSINESS OF AFRIKANDER BEEKEEPING

BY A. R. CLIFTON

The bees in this country are nearly all exceptions, or at any rate exhibit many exceptions, and this not alone in the hands of novices to which Mr. A. C. Miller attributes many failures.

In temper they are most variable. Many people handle them without smoke or veil;

time of the year when they were weak in numbers, and when no one was near. We found the donkeys about 100 yards from the hives some hours after they were stung. The illustration of a Zulu servant with an ax was taken on my home ground, and the field just visible in the background is where the donkeys were stung to death.

On another occasion a woman asked me to take her bees away because they had killed her mule. I found the three hives were in paraffin-cases with sacks thrown over them. These bees seemed mild-tempered, and under the sacks I found two snakes, which I killed.

Besides their temper, many other unusual traits are exhibited. They are very prone to start fertile workers, and I have seen eggs laid by them

while queen-cells and even fertile queens were in the hive. In the latter case, however, the fertile workers soon disappear. It is not uncommon to find from fifteen to twenty such eggs in a single queen-cell.

On the subject of fertile workers I heard

Just beyond, three donkeys were stung to death.

but they have been known to turn so vicious that they killed the person operating. They also occasionally kill fowls, dogs, and horses. Three weeks ago my bees killed four donkey foals which were loose in a large field fenced off from the bees at a

one of our largest local beekeepers state that he would guarantee that laying-worker eggs would produce *worker bees*, and he would demonstrate this to a number of experts or forfeit 20 pounds. My experience, however, has been directly opposed to this, though I have seen fertile - worker eggs in a colony that had a fertile queen, and which eggs were not hatched at all, in any case.

The bees in this country vary from a deep brown to four bands of yellow, those on the coast being the darkest on the whole, while in the high veldt of Orange Free State I have never seen a bee that had not at least three distinct yellow bands. Many authorities declare the bees of South Africa to be smaller than the Italian, and also to vary in size. Be that as it may, all naturally built comb that I have measured has the same size of worker cells, while American-made queen-excluders answer our purposes admirably.

The second illustration shows the opposite side of the same apiary, and my little

girl eight months old, whom you will observe, is being brought up to use a veil when with the bees. She hopes one day to be a great beekeeper.

The apiary is enclosed with high hedges of Port Jackson willows on three sides, and

The apiary is enclosed by high hedges.

pine-trees on the fourth side. These trees are quick-growing, and, when planted thickly, make good windbreaks. We had a severe windstorm this month. Several trees were blown down, one of which smashed a hive: but with this exception none of the hives were blown over.

Cape Town, South Africa.

ORIGIN OF ALBUMEN IN HONEY

BY J. A. HEBERLE, B.S.

If a sugar syrup with a trace of sodium carbonate and enough litmus color to make the syrup blue is fed to bees, and the alimentary canal of such bees is examined, the honey-stomach shows small air-bubbles in a red-colored fluid. These bubbles of carbonic acid, and the change of color from blue to red, mean that in the short space of time it took to imbibe and swallow the syrup an acid has been added. It is known that the acid is contained in the secretions of the salivary glands.

Dr. Langer had asserted, in giving an account of his researches on honey, that with the sour secretions of the salivary glands an albuminous body was added to the honey that afterward could not be separated from it. Dr. Langer was very much interested in demonstrating not only that the honey albumen was from the bee, but

he wanted to show that it is a product of the salivary glands.

The direct way to prove this by the biological method would have been to separate a considerable number of these very small glands and inject the watery extracts, and so prepare an antiserum. As the glands are so small it would have been a great deal of work; so he tried another way, which required much less work, and seems fairly free from objections.

Dr. Langer made watery extracts from separately triturated heads, thorax, and abdomens from field bees, and injected these to obtain the antisera. From these only the antiserum from the heads gave a small precipitate with honey albumen.

The result led to the supposition that the field bees were only for bringing the sweets, and that the younger bees had to complete

the change from nectar to honey. To investigate this supposition he used a very active honey antiserum, and tested separately a number of watery extracts of heads, thorax, and abdomens of bees of different age. Later he extended the investigation to drones and queens. The results are shown in the following table:

Material used in the experiments	Watery extracts gave ppts. in millimeter from the		
	heads	thorax	abdomens
Workers shortly after hatching.....	0.0	0.0	0.0
Workers from the.....			
brood-nest.....	17.0 m/m	0.0	trace
brood-nest.....	25.0 "	0.0	"
super.....	25.0 "	trace	"
Field bees.....	0.0 "	0.0 "	"
Drones.....	0.0 "	0.0 "	" ?
Queens.....	0.0 "	trace	30.0 m/m
Chyme from larvæ.....	Dilution of the chyme 1:10,000		
of the workers.....	4.0 m/m precipitate		
of the drones.....	16.0 m/m precipitate		
of the queens.....	30.0 m/m precipitate		

The conclusion to be drawn from the above is that the albumen in the honey is from an organ located in the head. This organ (salivary gland) in bees just hatched seems not to have started its work, while in the drone and queen it is either wanting or exists only in a rudimentary state.

It is known that in the head of the worker there are three glands; in the head of the queen, two of them, but only one well developed; while in the head of the drone there are also two glands, but neither of them well developed.

The table further shows what practical beemen have long known from observation, that the younger bees are the nurses of the colony. The newly hatched workers show no precipitates, the organs have not yet become active; but as soon as the glands of the young bees begin to secrete, the bees instinctively turn nurses and feed the larvæ. After a while the older nurses are replaced by the younger bees, and start to

go to the field. The secretion not used or needed is stopped; the glands become inactive. If, however, by force of circumstances, the old bees are compelled to feed the larvæ the glands become active again. The heavy precipitate shown in the table by the abdomens of queens may be explained by the fact that the queen receives as nourishment chyme from the bees in attendance. It is this predigested food the queen receives so profusely that enables her to perform the tremendous task of laying 2000 and even 3000 eggs in 24 hours.

To prove that the chyme fed the young larvæ is the secretion of glands in the head of the bee, Dr. Langer shook a colony that had considerable brood on empty combs, and fed them sugar syrup to which albumen from her eggs had been added, and then dequeened it. Several queen-cells were started with much royal jelly in them. He then examined the watery extracts of heads, thorax, and abdomen with egg antiserum. The abdomens showed a heavy precipitate with the egg antiserum, but the royal jelly gave no precipitate with the egg anti-serum. This shows that the bees add nothing from the contents of the stomach to the food for the royal larvæ, or the egg albumen is in the stomach of the bee so changed or reduced that it cannot be detected by the biological method. Dr. Langer concludes that the chyme used as food for the larvæ is a pure secretion of the glands in the head of the bees.

Fischer, a well-known scientist, said in 1874 that the chyme is a secretion of the salivary glands. These glands are, in the young nurse bee, a juicy organ, while in the old worker bee it has shriveled, leaving in the head an empty space of about two millimeters.

Bavaria, Germany.

A NEW STARVATION METHOD OF QUEEN INTRODUCTION

BY A. T. RODMAN

The method of introduction which I have used this season has proved the most satisfactory of any I ever tried. So far I have not lost a queen when I followed the rules.

But in the first place I must explain that all of my hives have metal covers with an inner cover under the metal cover. This inner cover has a half-inch hole near one edge. I lay a piece of section over this hole and tack one end so I can swing the other end around from over the hole.

I use West queen-cell protectors to cage my queens in. I place a little tube in the

small end of the cage, filled with queen candy. I make the tube by bending a very thin piece of tin. The tube is about $\frac{3}{4}$ inch long. The outer end is stuffed with paper. I catch the queen late in the afternoon or evening. When I locate the queen I place the large end of the cage over her. As soon as she crawls in on the side I remove the cage, closing the end by inserting the piece of tin between the wire coils. I now put three bees in with her for escorts, and lay them away till dark.

As soon as it is about dark I remove the

tubes and let the escorts crawl out. Then I replace the tube with the end stuffed with paper on the inside so she cannot get any food.

Queens thus prepared I leave alone for thirty minutes, and by that time they are quite hungry. Then I take them to the apiary and remove the outside cover of the hive. I remove the tube from the end of the cage and insert the small end of the cage in the hole of the inner cover. I leave it so, and go to the next hive till all are in place. When all are ready I go to the first one; and if the queen has not passed down I light a little smoked rag and hold it close to the cage and blow a little smoke on her.

She will pass down at once. Then I remove the cage, close the hole, replace the outer cover, and the job is done.

I have introduced queens to colonies that had ripe cells, and the virgins hatched the next day. I looked in the second day and found the old queen laying, and a young virgin which I removed. This has happened twice this season.

Three things to be remembered are that the colony must be queenless; the queen must be hungry, and she must be introduced after dark. As I introduce the queens through a small hole the colony is not disturbed at all, and I make as little noise as possible.

Kansas City, Mo.

HOW TO DO THINGS AND HOW NOT TO DO THEM. IV

Some Pointers on Comb-Honey Production

BY R. F. HOLTERMANN

A beginner in beekeeping has to face the question of what kind of honey to produce—comb or extracted. This is a somewhat difficult point to decide, especially if bees are kept in a small way and the article produced is intended for home consumption.

In the production of comb honey less equipment is required. If disease is prev-

alent it is less liable to spread, because the supers once taken off are generally permanently separated from the bees; whereas in extracting, wet combs are put back on the hives; and if not interchanged on hives they at least touch the extractor-baskets, and the honey is distributed. For any one who wishes to stop the bees from swarming it is more difficult to do this in the production

of comb honey. On the other hand, so far as I know there is a better demand for comb honey; and, in case of the extensive and experienced beekeeper in a good locality, more money can be made out of the production of comb honey in most markets.

The question of whether to produce comb or extracted honey is one which the beekeeper will have to decide for himself.

FULL SHEETS OR STARTERS IN SECTIONS.

Contrary to the practice of many, I unhesitatingly advise the producer of comb honey to use full sheets of comb foundation as in Fig. 1, and not starters as in Fig. 2. With

FIG. 1.—With full sheets of foundation the bees enter the supers more readily.

FIG. 2.—I unhesitatingly advise against the use of starters.

full sheets the bees enter the supers more readily, and in that way the bees are less liable to crowd honey into the brood-chamber and swarm.

Fig. 3 shows sections built on full sheets of foundation, and Fig. 4 shows the section honey built from small starters. When selling such honey as in Fig. 4, the best price is not obtained, and the honey will not stand the jars and bumps that that in Fig. 3 would.

FIG. 3.—The consumer prefers the well-filled section.

I have done a good deal of comb-honey shipping; and unless the comb is well attached to the wood I never know in what condition the honey will reach its destination.

Then, too, selling honey by the pound each section weighs less. I have heard some people say that if the section is not filled

next the wood it cuts out more readily. This is very thoughtful and considerate; but the consumer rarely sees matters in that light, and will prefer the well-filled section. Some may not like it; but I think the net-weight law for comb and extracted honey is a good law. The consumer knows what he is getting, which he has a right to know. I wish we had to put up our honey in that way in Canada. It would be fair for all.

In closing I should like to add an item

FIG. 4.—The best price cannot be obtained for such honey.

in favor of comb-honey production. Owing to the limited room which can be given in the supers, at the close of the flow there is generally more honey in the brood-chamber, and the colony is thus better provided with fall and winter stores.

Brantford, Canada.

THE LET-ALONE PLAN

BY S. M. CAMPBELL

It is time that something be done to help the beekeepers, especially in California. It has come to the point where bees will not pay expenses at the price honey is selling this season. There are many tons selling at 3½ cts. per pound—cheaper than sorghum molasses. The beemen are up against a hard proposition, and will have to cut down expenses or go out of the business.

Here is my plan to help them out in working bees efficiently. A little further on I will tell how I worked this plan successfully in Arkansas, and I know it will work in California.

Suppose a man has 600 or 700 colonies. Instead of employing two or three men, work them with but one man, and do not put in so much time. It does not pay. In the first place, have all the super room you think they will fill. We all know that this is the main thing to control swarming. Of course it will not keep them *all* from swarming; but when we get all this plan together we will knock swarming out; and swarming is what the beekeeper dreads.

Suppose further that we have outyards. The first trip in the spring will be to inspect each yard and equalize the honey. Be sure that each colony has forty pounds to commence with in the fall. I have found that this amount is somewhere near the amount it takes to winter a strong colony here in southern California.

The second round will be to equalize brood. Here is where you can overcome swarming. Don't do this too early nor wait too late. When it gets warm, and some of your colonies begin to get strong, open up the hive and take out two or three frames of brood and give them to the weaker hives. But do not give over two frames to any one colony at a time, for if you do it will make them ball their queen. Always give drawn combs in place of the brood you take away, as it is much better than foundation.

Be sure you have your hives three stories high, and four will be better. If you want to make fewer trips you can put the room on all at once. In case you do not care to

put the supers all on top you can put one or two underneath, and the bees will work down when they get full above.

I think there is much harm done by going through the bees too much. Learn to work fast with bees. Get the notion out of your head that you have to work slow. If a man has 2000 colonies of bees he needs only three men. Commence in time. It is much better to give them too much room, or a little too early, than not enough or too late. This is not guesswork, as it has been done by the writer, who located at Mineral, Ark., in the year 1900. That year I had 180 colonies of bees and 35 acres of small fruit. I made \$1250 on the bees, and with just a few trips. They were in three yards. The furthest one was fifteen miles from home. To show what can be done, I made \$11.00 a day for the days I worked with the bees from the time I started in the spring until the honey was sold.

I peddled the honey from house to house at 12½ cts. a pound. It was bulk comb honey, as that was before they had begun putting honey in buckets. I hauled it to market in new wash-tubs. I used the 5¾ frame, cut the honey out, and laid it in the tubs. It was a good advertisement—nice comb honey stacked clear above the top of the tub. I did not miss many sales because of the honey being in a tub. They were nice bright tubs, and I had a clean cloth

tied over the honey to keep the dust out. When I got to town I always got a boy to drive my wagon, and I worked both sides of the street.

I especially remember our trip to Jenny Lind, Ark. This was a mining town; and as the miners had been paid the day before, they all had money, and I sold \$100 worth of honey that day.

But I do not claim to have done all this work myself, for I did not. I had a good wife to help me. That year we made \$2400 from our bees and fruit. But she died five years ago.

Bees have not made much of a crop in this section. Mr. D. R. Taylor, the man I work for, got a fair crop. His bees—550 colonies, spring count—made eleven tons of white honey and about four tons of amber from sumac. Mr. Taylor does not put the sumac honey on the market, but keeps it for spring feeding, for which it will be just as valuable as the honey he sold. He also increased his colonies to 1200. He is building his bees up by dequeening in the fall and replacing with young Italian queens from two fine breeders. They are the nicest bees to handle I ever saw. I have been raising his queens for three months now, and have opened the two breeder colonies to graft cells from nearly every day, and have never been stung by these bees, and I handle them without veil or gloves.

Nordhoff, Cal.

MICHIGAN'S FIFTIETH ANNUAL MEETING

BY F. ERIC MILLEN, *Secretary-treasurer*

On December 15 and 16 the Michigan beekeepers will hold their fiftieth annual meeting at Grand Rapids. This meeting promises to be one that will set a new record in interest and attendance, and one that will be remembered by those present as the best ever held.

One of the special features will be a banquet supper on the evening of Dec. 15. This banquet is the gift of Messrs. G. C. Lewis, Watertown, Wis., and A. G. Woodman, Grand Rapids, Mich. A banquet, at which all the members get together, seems to add a finishing touch to any gathering; and we feel sure the beekeepers will show Messrs. Lewis and Woodman their appreciation by turning out in record numbers.

The program will be brimful of good things, and many of the notables of the beekeeping world will be there. A full program will be published next month.

The headquarters of the association will

be the Eagle Hotel. This hotel has been our headquarters on many previous occasions, and is well known to the beekeepers. Rooms can be obtained from 75 cents up.

Many beekeepers do not attend meetings of this kind because they fail to realize their full value. The program alone will repay the trouble of attending, but this is only a part. The beekeeper who wants to learn more about his bees or about disposing of his crop of honey is usually able to obtain this information in personal discussions with the other beekeepers present. Send us your questions any time, and we will endeavor to answer them in a satisfactory manner at the meeting.

Every beekeeper in Michigan is invited to attend, and is expected to bring another beekeeper along and join with us in making the fiftieth annual meeting of the Michigan Beekeepers' Association "bigger'n ever."

East Lansing, Mich.

An apiary of ten colonies has been added to the farm.

SOME VANCOUVER BEES AND BEEMEN

BY BEVAN ARGYLE

Here is a view of part of the Dominion Government experimental station near Sidney, Vancouver Island, B. C. Mr. Samuel Spencer is in charge of the farm, which is situated at the northeast part of the Saanich peninsula. The usual test plots of cereals are well looked after, and the farm is now showing the good work of the superintendent in the fine ornamental shrubs and plants.

Last year an apiary of ten colonies of Italian bees was added to the farm. There

are now twelve ten-frame hives with adjustable openings to regulate the entrances. Every assistance is given to the farmer and beekeeper by the official in charge. The photographs show two enthusiastic beekeepers. Mr. Walter Luney, one of the largest building contractors in British Columbia, is on the left of the picture. He finds a pleasure and an interesting recreation in his hobby. The beekeeper on the right is Mr. William Hugh, also of Victoria, B. C.

James Bay, Victoria, B. C.

DIFFICULTY WITH FALL HONEY A MATTER OF CLIMATE

BY J. D. FOOSHE

From the fact that some have succeeded in wintering bees on goldenrod and aster while others have failed, I think we are obliged to attribute it to weather or climatic conditions. When I was in South Carolina the goldenrod and aster were the only sources of fall honey, and in some years the heaviest flow of honey during the whole year would be from these sources; but I never had any difficulty in wintering successfully on them.

Sometimes when we had a rainy season in October the honey was slow to ripen, and a few colonies would have more dead bees about the entrance, under these circum-

stances, than when the weather remained dry and warm. I have extracted quantities of aster and goldenrod honey about the last of October, and still had plenty for winter stores; but very singular conditions prevail in this locality. I have been here now four years, and goldenrod and aster bloom profusely, yet I have never known bees to gather a single bit from this source. When they get their stores from cotton, peas, sumac, and other sources they seem to be done for the year. I am located in a very dry atmosphere. Peaches, grapes, and strawberries do well here, and I have never seen any disease on any of the fruit.

Augusta, Ga.

MAKING AN AIR-TIGHT FENCE

BY NOAH BORDNER

In the view of my apiary of 84 colonies, notice the windbreak. This is made by bolting a strip 1x3 inches on each side of the fence-post with a block 3 inches square and $1\frac{1}{4}$ inches thick, between the strip and post at the top and bottom end of the strip. By doing this I can slide all the boards in these slots in the winter without using a nail, and take them out in the summer to give all the air possible in the apiary. I used posts 5 inches thick, so it requires two bolts $\frac{1}{2}$ x 10 inches to each

The windbreak fence can be seen in the background.

post to reach through strips, blocks, and post.

Holgate, Ohio.

WINTER CASES—AN INTERVIEW WITH DR. E. F. PHILLIPS

BY L. A. P. STONE

A few months ago the members of the beekeeping fraternity were invited by Dr. Phillips, in Charge of Apiculture in the United States Bureau of Entomology, to call on him at his experimental station. Mindful of this invitation, while in Washington some time ago I decided to pay him a visit, and was more than amply repaid in doing so.

I began the conversation by asking his advice on what I consider the greatest problem to northern beekeepers, the problem of wintering. "What is best and in the long run, the cheapest wintering-case for protecting bees in the climate of Ontario?"

"I think that the quadruple wintering-case, such as is used by Mr. Holtermann, is best, except that it may be well to make the case high enough to winter the bees in two-stories. My reason for the two-story idea is that, during our study of the question, I have come to the conclusion that it is far safer.

"If colonies are weak in going into winter quarters they are not an asset in any kind of case; while an ordinary strong colony, if wintered in two stories, well packed in a quadruple case, will build up

stronger and steadier in the spring with two stories than with one."

The two-story idea was not entirely new to me; but still I had never had so able an authority as Dr. Phillips recommend it before, and I feel that it must, therefore, be well worth trying. I believe Mr. O. L. Hershiser told me that he had tried it with one or two exceptionally strong colonies, and was quite astonished at the splendid way the bees came through the winter. He seemed rather cautious in recommending it universally as was Dr. Phillips.

Another interesting point discussed in our conversation was one which GLEANINGS has discussed—degree of temperature at which bees winter best in their cluster.

"The temperature should be about 57 degrees Fahrenheit; and the better this temperature can be kept by the bees, the better the wintering; because, above this point, bees tend to brood-rearing, while below it the bees are forced to exercise to keep warm. Bees have little recuperative power, as do human beings, so this extra exercise only shortens their period of life. From my observation the quadruple wintering-case is best for maintaining this temperature, and

the more packing the better. There can never be too much packing.

"In regard to wide entrances in a wintering-case," Dr. Phillips continued, "these are harmful, because they expose the bees to heavy winds."

In continuing our intercourse, the subject of sweet clover came up. I could not help telling Dr. Phillips of the hostile attitude that the majority of farmers in Ontario have for this plant. Even at the Ontario Agricultural College the majority of professors were opposed to its general use, and condemned it as a noxious weed. Were it not for Professor Pettit I am convinced that sweet clover would never receive any

mention whatsoever. I also told Dr. Phillips that in my own country, in spite of the protests of farmers who realized the value of this nitrogen plant, it was cut down along the roadsides along with thistles and mustards.

The doctor stated that the United States government had prepared a booklet on sweet clover, not overemphasizing its value to the beekeeper, but explaining its good qualities to the farmer. This booklet is to be had for the asking, and he suggested that it would be a good thing if every beekeeper would send for it and show it to the farmers in his vicinity.

Erie Beach, Ont.

CALIFORNIA SNAPSHOTS

BY CHARLES S. KINZIE

In my outyard illustrated the rows are seventeen feet apart with eight feet between the hives in the row. I call this my non-swarming apiary. The three rows are long, forty-five hives in a row, and the apiary is narrow. When the young bees and drones come out from 10 to 4 o'clock they do not become confused.

The apiary is in the sage foothills. I saw but one swarm from it this year. In my Orange Belt apiary I have my hives in a closed square, and had over thirty-five swarms from one hundred colonies. One

day I saw a swarm come out about 1 o'clock when the drones and young bees were flying. I looked at the hive they came from, and there were only queen-cell cups. Excitement had brought them out.

My honey-store is located in my home. It has shelves and a large window in front to display the honey. Last year I sold three tons in this way—tumblers, quart cans, gallon and five-gallon cans, and in the comb.

The third illustration shows my automobile and trailer which I use in apiary work. Arlington, Cal.

I call this my non-swarming apiary.

VARIOUS PLANS FOR WINTERING WHICH WERE SUCCESSFUL

BY W. D. SELLERS

As my increase is gathered in the shape of swarms from the farmers, so my opportunities each year to see how the bees have wintered are wide. About the time that the maples are in bloom I start to make my round among the farmers. Mr. A. last spring said he had saved all his bees. They were wintered in eight and ten frame hive-bodies—no absorbent material above them—just the cover glued down on the body.

Mr. B. said that he had lost one out of twenty colonies. His hives are eight-frame. He also uses no absorbent on top of his colonies. He had some air-spaced observation hives which showed up better than the ones in single-walled hives.

Mr. C. had not lost one colony out of twenty. His hives are all air-spaced observation hives wintered with sealed covers. Not seeing any bees working out of one of his hives I asked him whether it was alive, at the same time bumping my foot against it. I was again surprised to find the hive overflowing with bees.

Mr. D. had not lost a colony either. He wintered his bees in ten-frame hives with a super cover glued down on top of the hive-body with telescope cover.

The most of Mr. E.'s bees are in air-spaced hives, and some in ten-frame. He wintered his bees with the supers on, with partly filled boxes and comb. He lost one colony out of thirty-five.

Mr. F. has some 30 colonies, and had not lost one. He requeened with all young queens last fall, and wintered them with a wood-bound wire queen-excluder on top of the body, with a super of planer-shavings on top of this. We wintered with the $\frac{1}{8}$ -inch bottom-board turned up, and had the front of the board loose. He showed me some of his colonies by looking in under the frames. Some looked extra strong, some weak. He feeds artificial pollen early, and, later, sugar syrup.

The majority of beekeepers visited do not use absorbents at all on top of their hives, and I find that most of their colonies are storing during fruit bloom. Some of them never look into

the brood-chamber from one year's end to the other. Their bees swarm every year, so they have fine large young queens with

Last year I sold three tons of honey in my store at home.—See preceding page.

plenty of honey; and, not being disturbed, they raise large colonies of bees early in the season.

I visited another beekeeper, Mr. G. As he was not well, he was selling out his bees.

A trailer solves the problem for outyard work.

He had one colony left, and this one I looked over. It was wintered in a single-walled double-story eight-frame hive with 16 frames—8 below, 8 above. The colony was in better condition than any colony I found this year. This is the nearest thing to the old-style box hive which stood about 18 inches in height. These old-style box hives, single-walled, come out in the best of condition every year here. Colonies in ten-frame hives with a body of extracting combs on the top, put on early enough so the bees would have saved this colony.

THE LEAN YEAR IN NEW SOUTH WALES

Sugar for Feeding an Impossibility

BY A. P. HABERECHT

Our past season has been one of the worst in the states; nevertheless it was just as I expected after last year's crop. In all my experience in Victoria and New South Wales, a bad season always follows a good one. What I call the "off season" comes about every seven years.

I extracted only 1740 lbs. of honey, which I really left in the supers from the season before last. I sold it all at 4 pence a pound months before I extracted it, and now I could get 8 pence for it readily. There is no honey to be bought here.

There are hundreds of colonies dying of starvation—no honey and no sugar to feed them. The most sugar a housewife can buy at a time is two pounds, and price is 3½ pence. Therefore the poor bees that have been unable to secure enough stores for their winter use are doomed to die of starvation.

I expect the loss of bees in this district to be about a half next season.

My own bees, about 56 colonies, have plenty of stores to see them well into spring; but they are all unusually small, covering about three full-depth L. frames, and some perhaps only two frames. But I do not expect to lose more than about one-fifth of them. There is plenty of nectar for them to work on. The yellowbox is out in bloom, and the capeweed will be out at the end of this month, which gives abundance of pollen. On calm sunny days my bees will work just as they would in spring time for about four hours toward noon day.

I noticed no disease of any kind last season—no robbing, but wax or bee moth by the million. Although I never lost a single colony, I have lost many stored empty frames of comb.

Henty, N. S. W., Australia.

A DOUBLE-ACTING QUEEN AND DRONE-TRAP

BY B. R. CURTISS

In order to construct a trap that will catch the drones and queens from both the hive and the outside at the same time, place the excluder in the center of the trap and have a passageway on both sides of the excluder leading up into the trap.

The excluder could be made in the new wire pattern with an enlargement on top of the upright bars on which to fasten the bottom of the trap.

In order to keep the drones from crawling out through the passageways it would be necessary to have the excluder extend up into the trap a short distance; then when the drones come to the opening, instead of going down they would crawl up over the excluder.

The trap would have this advantage: It

Catching them coming and going.

could be placed before the hive at any time of day, and catch the drones that come in as well as those that go out.

Wallowa, Ore.

WINTERING WITH THE FOUR-COLONY CASE

BY A. J. KNOX

For a number of years I have wintered almost all my bees (in three apiaries) in the four-colony wintering-case. I do not know who was the first user of this case in Canada; but I had my interest awakened by a study of the case, illustrated and described by Ira C. Bartlett, of Michigan, and published some years ago in *GLEANINGS*.

My first dozen cases were made out of inch stuff. The hives were raised three inches from the floor, with packing underneath. They had six inches of packing space all around the sides, and ten inches over the top.

A winter's experience with these, where the snow completely covered them for several months, proved disastrous. In the fall I had leaned the covers over the entrances to protect them from the wind and snow. This, combined with the high temperature inside the case, under the snow, caused the bees to start brood-rearing too early, with the result that they came out (probably in search of water) into the cavity under the leaning cover, and, being chilled, never got back. When the snow melted away from the cases, bees could be shoveled up with a scoop.

After some correspondence with J. L. Byer I decided to make my future cases with only three inches of packing on the fronts, the rest remaining the same depth to set the hives directly on to the floor, close together, and with no packing underneath. Further, I now place no boards over the entrances, preferring to have the snow drift solidly around the cases and up over the entrances, keeping the wind out and the bees in.

Since that change, wintering has lost its terrors, for, with plenty of bees and feed, I have good results. At the Newcastle yard last winter, I lost only three out of seventy-five colonies.

I now have seventy-five of these cases in use, and most of them are made of ordinary clapboard siding rabbeted on the lower or thick edge. This makes a smooth inner wall at a minimum of lightness and cheapness. The cover is of half-inch pine lumber, made to telescope two inches, and covered with paroid roofing. The floor is of half-inch pine, nailed to four sills, one by four inches by the width of the case. The walls of the cases go together with hooks. The posts, three to a side, and one by two inches in diameter, rest on the floor, the walls running down half an inch lower, covering the floor, and thus shedding water.

The entrances are cut three-eighths by six inches, as wide apart as the bottom-boards of the hives will allow when shoved close together; and I find it well to have the entrance about an inch above the hive floor, to allow for lack of uniformity in depths of hive-bottom boards.

When set up, the case stands on two cedar scantlings three by five inches, which leaves the entrances about eight inches from the ground.

The cases are painted with red creosote shingle-stain at 75 cents per gallon. This seems to be answering the purpose as well as lead and oil paint, and is decidedly cheaper, and easier to put on.

The packing material used is planer-shavings. It is clean and easily handled, and mice don't work in it to any extent. Cut straw is bad on account of the mice, and leaves can never be obtained in sufficient quantities. Six two-bushel baskets of shavings are required to pack one case containing four ten-frame Langstroth hives.

In the yard the cases are placed in rows about eighteen feet apart, entrances facing east and west. The corresponding squad of hives is placed just four feet south, thus allowing working room between.

With this arrangement, and the packing all in the cases, it is a pleasant and simple job to pack up a yard, taking from thirty to forty minutes per case, with two men on the job.

To pack, start at the end of a row with an empty case. Dismount the case, lift the four hives of bees to one side, drag the floor over to the place recently occupied by the bees. Place the hives back on the floor in the same relative position as before; hook up the sides of case and put in the bridges. Then go to the next case in the row, scoop out the packing with two-bushel baskets, and dump into the case just prepared for it. You now have the next case empty, and ready to operate on as before. In this way you have no lugging around of cases, and no hauling of packing every year. I see nothing to prevent the packing from lasting twenty years, with the possible addition of a few extra basketfuls now and then. I use the same packing continually, for smoker fuel. Nothing else is equal to it, and certainly nothing so handy.

This plan has been worked out so that there is a minimum of labor and expense. By this arrangement the cases act as a screen or windbreak while working with the bees during the summer months.

In an exposed location it is necessary to put a screw-eye in the cover and case, on two sides at least, and tie on the covers. Hooks will not answer, as they jar out with the wind. Unless the wind goes over forty miles per hour, I find the covers need no tying down; but having suffered from high winds on two occasions, tying down is now the final touch in my winter preparations.

When the snow comes I prefer to see it drift around the cases; and if it does not, and there is any handy, I shovel it around

the case. Snow is the best bottom packing to be had; and the best wintering seems to take place when the cases are covered with snow up to within a couple of inches of the top. This gives complete protection from the wind, and allows of upward ventilation through the packing. With the case completely covered with snow, especially during the latter part of winter, there is danger of too high a temperature in the hives for the best results.

Orono, Ont., Can.

WEATHER CONDITIONS IN WEST VIRGINIA

BY W. C. MOLLETT

The season which is drawing to a close has been one of the most peculiar for a great many years. It was dry here in February, and continued very dry till May. During fruit bloom the weather was warm and fine, and the bees built up very rapidly; but in May the rains began, and kept up with such persistency that the bees were upon the brink of starvation in the first half of June. Then just as the basswoods were coming into bloom the weather improved, and the flow from this source was remarkable for about two weeks, when the rains set in again worse than before.

The bees had made a fine surplus from basswood while the weather was dry and warm; but the rains interfered with the honey-gathering from the last of the basswood, and completely ruined the sourwood flow, as it was so wet and cloudy that the bees could not fly for a long time. From July the rains continued till September 1, and the bees were again in danger of starvation, and again the weather improved just as the fall flowers were coming into bloom.

For about ten days the bees carried in nectar as fast, almost, as I ever saw them from basswood or any other source; but again the cold wet weather set in, and there was no honey-gathering for several days until the fall flow was almost over. At the winding-up of the nectar-gathering the weather was fair and the bees were enabled to work quite strongly upon the last of the aster blooms.

I do not think they will have quite enough to carry them through the winter; but I have seen them in worse condition at this time of the year. It is usually safer to feed some here rather than to take chances, as the consumption of stores during mild winters is something surprising. I am sure

that, for outdoor wintering, which is the only way here, it will take about fifty pounds to winter an average colony. Although the weather conditions as a whole were very discouraging here, the bees secured a surplus of at least thirty pounds per colony, which is not as bad as it might have been.

I notice that the same conditions prevailed in most of the white-clover regions, so that possibly the crop may not reach any thing near that of average years. In localities that sometimes have a heavy rainfall the bee business is liable to be affected by the wet and cool weather almost any season and for this reason the beekeepers are apt to become discouraged, and quit the business. However, if one season is bad the next is likely to be better, as the weather usually keeps a pretty close balance. We are sure to have a bad season now and then, but in the long run we are very liable to come out all right. There is no cause for discouragement.

Stonecoal, W. Va.

A St. Louis Summer

This has been a peculiar season, I should say, though my experience goes back only three years. It has been supers one week and feeders the next. The white clover began to bloom about May 21, and is still in bloom. Very little honey has been secured from it, both on account of the lack of nectar and the bad weather.

Yesterday I saw bees working on white clover and smartweed in the same field. The past week has been the best one of the season, and I look for fine fall weather and a good flow from now till frost; and if the asters yield as they did last year I shall have enough to winter the bees and then some. My bees wintered in good order on the aster honey, though I had a large proportion of colonies queenless in the spring. That set them back; but they are nearly all in fine condition now. I have eleven colonies at present.

Webster Groves, Mo., Sept. 7. F. A. COLDWELL.

Heads of Grain from Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

These city people are mighty particular about some things. Last summer when the bees were working on milkweed a man on Main Street put door mats down in front of the hives so they could wipe their feet.

A Telegraph Operator's Bees

We have had but very little sunshine this season, and the crop was almost a complete failure here. The early flow was of a fine flavor, but the later honey was almost like water and of a mint flavor. Although I had 8 colonies to start with this season I got only about 50 pounds of honey from them. It was of a dark color from leaving it in the hive so long because it was not finished. I sold every section for 20 cts. each, and could have sold many more if I had had it. I did not get out and try to sell any for I did not have it. They all came to me after it. I often think if the beekeepers would only ask a little more for their honey they would sell almost as much.

I am a telegraph operator for the Pennsylvania Company. I have a second "trick" from 3 P. M. until 11 P. M., and have always had a desire for bees, as it makes a good side line. It seems as if I lose almost all of my bees every winter from cold weather. I had a little experience with American foul brood three years ago. I burned hive, bees, and all; also buried the ashes pretty deep, and have had no signs of it since.

I have read every article I have seen on how to prevent swarming. I have not tried any of the plans, for I believe natural swarming is the best way to make increase, and I do not believe there is anything that will prevent the bees from swarming,

or at least trying it. I had a swarm come out Sept. 7, this year, but they went back and saved me the trouble of putting them back. That is the fourth swarm since July 1. Three of them came from young swarms hived the last of June this year. I say it is the nature of bees to swarm, and their only way of increase, and there is no way to prevent it totally, although plenty of room and a little shade will prevent it to a certain extent.

Bradford, O., Sept. 7. CURTIS C. GROOMS.

175 Swarms from 70 Colonies, Spring Count

After keeping bees over 65 years I find I know but little about them. I always thought that if I had ten empty hives to 100 colonies I had plenty; but it was different this season.

On the first of June I had 70 hives with few bees in each. I had them all plugged up to one bee-entrance, and hardly a bee stirring. About July 1 I had a swarm off, and I began to examine them, and I found them loaded with brood.

About July 15 they began to come off, and I had 40 swarms in four days, and I never saw them get honey faster. They kept it up until September. I have 174 colonies now, and I presume I have lost 12 or 15, which got away to the woods. Eleven had been found within two miles.

I secured about 5500 lbs.—not a big yield if there had been a good lot of bees and no swarming. It all sold as fast as taken from the hives. I never saw nicer honey—no travel-stain nor water-colored sections.

I had in all something over 175 swarms. I doubled them up all I could—three swarms in some of the hives. The colony that swarmed first I moved to a new place, and hived the swarm on the old stand. The parent colony made me over 100 lbs. of comb honey, and then swarmed again about the middle of August.

West Rupert, Vt., Sept. 6. C. M. LINCOLN.

The Tenement Hive for Summer as Well as for Winter

I have used the four-hive case exclusively since 1885. I soon saw the folly of unpacking the bees for the summer. If the frames are as movable as they should be they may be quickly taken out just as well from the hives in the case. If large loose sawdust cushions remain on all summer the conditions are ideal; for the hives are cool during the hottest part of the day and warm during cool nights. In actual practice I seldom see bees doing very much fanning.

The case should be 30 inches deep so as to hold two supers at least. The roof should be half pitch, and the large gable should be open in summer. The roof should project over the sides at least $\frac{3}{4}$ inch. For convenience I have the upper half of the case hinged. I use no packing under the hive.

Little Britain, Ontario. R. F. WHITESIDE.

The Cause of Late Swarming

In regard to late swarming, my bees have not developed this abnormal condition for several years; but I have had many swarms in August and September—one as late as September 28.

With my bees, this unnatural swarming mania developed just after a short heavy honey-flow which suddenly stopped. Foundation was drawn out in supers in anticipation of a harvest which never came. Every swarm came out with a most stubborn determination to abscond. Reasoning from these two

facts, I decided that it was disappointment and disgust over the failure of a promising honey harvest that caused the late swarming. The migratory instinct is strong in bees under normal conditions; and when for any reason they become discouraged and dissatisfied with their environment, is it unnatural or natural that they should "Seek fields anew and pastures green" even at unseasonable times?

I find no bad results following late swarming if care is taken to see that no colonies are left queenless or too weak to stand the winter.

Aurora, Mo., Oct. 6. FRANK M. McMURRAY.

Raising the Price of Honey

We have been producing honey for only two years, but have had fair success in establishing a local market. I believe there are a great many beekeepers shipping their honey to distant markets and not supplying their own town. Shipping honey to distant cities is not only very expensive for high freight and express charges, but the loss by leakage of comb honey is sometimes great.

We have been selling our honey mostly to consumers. Our competitors sell their honey for 15 cents per lb. We sell ours for 20 cents just as easily. One lady told me the reason she preferred our honey was because she knew it had not been exposed to flies. I assured her that our honey was produced and handled under strictly sanitary conditions. This alone will go a long way in selling honey to women, as they realize the importance of sanitation.

There has been a great deal said in the bee-journals about maintaining the price of honey. But we decided to raise the price five cents a pound at the very beginning.

Oak Grove, Ky. BRYAN STROUBE.

Why Requeening Does Not Always Regenerate

In my experience of requeening habitually poor colonies I have frequently found that the new queen does little or no better, and I have had colonies that, while they were given a new queen every year, remained useless to the end. I have not tested this myself, but I think I have now found the reason.

A colony that is always in a poor condition is so because the bees commencing from the larval stage have not been fed properly, and they in turn do not feed the new queen's larvae in a proper way; consequently, when the new bees hatch they lack vigor, and so this goes on all the time. The remedy for this would probably be intensive feeding for fully three months after requeening, which might force the old bees to establish a vigorous progeny; but I am doubtful, as their way of rearing their young may be constitutionally bad.

FRED B. HOOPER.

Liguanea, Jamaica, B. W. I.

A Queen Whose Eggs Fail to Hatch

I have in my possession a supersedure queen that commenced to lay about July 10. Four weeks later I noticed that this colony was slowly dwindling away, and on examination found five frames containing eggs but no larvae. I transferred the queen to a queenless nucleus and gave the colony a good queen. Both were accepted without challenge. I have kept the queen ever since for observation, but to date not an egg has hatched.

I have had about everything in the line of fresh queens, but this is a new one. Do you know of a similar case?

Berea, O., Oct. 4. W. H. DANALDS.

[It sometimes happens that a queen that has been laying fairly well, and whose eggs have hatched,

will later fail to hatch; but when that takes place such a queen is of no further use. It is more common, however, to find a young queen that lays regularly whose eggs will not hatch and never did hatch. Of course, such queens are worthless and should be destroyed; but it is rather uncommon to find a queen whose eggs have hatched regularly and then later on fail to do so.—Ed.]

Uniform Success with Winter Cases

For four years I have used tenement cases for two, three, and six hives, and have had uniform results. In the winter of 1913 I wintered one yard of thirty colonies with a very small loss. In 1915 I wintered fifty-six colonies with a loss of four. I could not see any difference in the different sizes of cases. My cases are built so the entrances are all in the same side of the case and facing south.

Kirkwood, N. Y.

J. STUART SCOFIELD.

How to Handle Laying Workers

When a colony contains laying workers, move the hive about thirty or forty feet and put in place of it another hive containing a frame or two of brood and a queen, together with empty frames. Then shake all bees from frames in the old hive on to the ground, removing the hive and frames. The bees shaken will at once go back to the old stand and the new queen. The laying workers are either too heavy to return or are treated as intruders and destroyed. I tried this with one colony, and it worked perfectly. These instructions were given me by one of our state inspectors, Mr. Charles Stewart.

Palmyra, N. Y.

G. H. PARKER.

A Satisfactory Cellar

The cellar I made for my 74 colonies is 6 x 10½ x 6 ft. There are 18 inches of sawdust between the inside casing and outside. Ventilation is through the center of the room at the top.

As we have sand here it did not need a wooden floor, only the earth. Two doors, one outside and one inside, keep the frost out and allow me to look at the cellar at any time. The temperature keeps about 45 degrees, never below 42, and not often over 50.

There was some dampness which can be prevented. The bees remain quiet the entire season in the cellar.

Last year they were put in December 9. A two-inch rim was placed between the hive-body and the bottom-board. Both the covers and the bottoms were left on, and the two entrances left open—one at the bottom-board and the other between the rim and the body.

Grand Rapids, Wis.

CHARLES PRITCHARD.

Never Too Late to Treat Foul Brood

Is it too late to do anything for European foul brood this season?

Ladd, Ill., Sept. 29.

JOHN WOLF.

[It is by no means too late to do something for European foul brood this season. In the first place, we would recommend you to Italianize all your bees with the very best Italian stock that you can secure. Generally, you would get better results with leather-colored; but some strains of bright or golden Italians are just as good for resisting European foul brood. This is the initial step to cure European foul brood. You may not have to do anything more next season than to dequeen for about ten days, and then let her loose again. See Dr. Miller's directions given in a recent issue of GLEANINGS.—Ed.]

OUR HOMES

Editor

To this end was I born, and for this cause came into the world, that I should bear witness unto the truth.—JOHN 18:37.

No weapon that is formed against thee shall prosper; and every tongue that shall rise against thee in judgment thou shalt condemn.—ISAIAH 54:17.

Fear thou not, for I am with thee; be not dismayed, for I am thy God; I will strengthen thee; yea, I will help thee; yea, I will uphold thee with the right hand of my righteousness.—ISAIAH 41:10.

When I was about ten years old, on coming into the schoolroom one morning, I, with the other pupils, was wondering what a certain sentence on the blackboard meant, written in a beautiful hand as follows:

"Magna est veritas, et praevalet."

When the teacher came he explained to our curious and inquiring minds that a friend of his, a college graduate, had just paid him a visit; and while in the schoolroom he picked up a piece of chalk and wrote that motto. He said it was Latin, and when translated into our language it meant "Great is truth, and will prevail." During that whole day many curious eyes were cast now and then on that beautiful specimen of penmanship. I always had a love for language and words; and even at that early age I decided that the word *magna* meant something like our word *mighty*—truth is mighty; and the word *veritas* I figured out meant something like our word *verify*; and the last word, *praevalet*, it was easy to guess, meant to prevail or become established. And all along these 65 years I have wondered again and again if the truth will finally prevail over falsehood and tangled-up intrigue.

In our temperance work, the liquor party will get hold of a little bit of truth. They exaggerate and twist it, so that sometimes even good and honest men get rattled. A few days ago while at our dentist's he asked why the Y. M. C. A. of Medina Co. gave up its regular meetings during hot weather. He asked me if I ever heard of *Satan* taking a "vacation" because the weather was hot or business was dull. And I am not sure but that at such a time, when people are off on an excursion, or are taking a vacation somewhere, it is the time when *Satan* gets in his best licks. *He*, at least, is untiring.

On p. 333, Minnie J. Ellet tells us that a Summit Co. liquor-license commissioner said Kansas was finding prohibition a failure, and that Kansas would have to go back to license, etc. Well, this story has gone out far and wide; and although the people of Kansas, and especially the governor of it,

has taken every precaution to have it contradicted, it is almost impossible to keep up with the lie—a lie made out of whole cloth; for, so far as I can learn, there was no foundation at all for such a newspaper falsehood. It seems to verify the old saying that "a lie will walk around the earth while Truth is pulling on his boots." With all the methods of communication, with our magazines, weekly and daily papers, telegraphy, including wireless, is it going to be possible to contradict the falsehoods and keep *truth* before the people? Years ago it was my privilege to listen to a talk from Anthony Comstock; and we frequently have newspaper notices that he is still alive and protecting our people, especially our boys and girls, from something that may be even *worse* than strong drink—from something that usually goes hand in hand with strong drink, and which would hardly keep alive if it were not for the help that it gets from saloon-keepers. All along during Comstock's faithful service, every little while a report is started, saying that the Postoffice Department has dropped him or given him up; and lately it has come out in the papers once more.

The Sunday School Times of a recent date, when commenting on the matter, had the following:

"THE FALL OF COMSTOCK."

That was the headline of a recent newspaper editorial.

For Anthony Comstock has had a fall.

But he has fallen on top of his enemies.

And Mr. Comstock is a very heavy man.

His feet are not small. And when he falls, he has a way of landing squarely on both feet, with his enemies underneath.

It hurts when Anthony Comstock falls.

But it doesn't hurt him.

You'll be interested in reading the Open Letter story of his "fall."

Then you'll want to know how it is that for more than forty years Comstock has landed on his feet.

He has had more savage enemies than almost any other man in our generation.

They've tried to bribe him, to discredit him, to kill him; and they couldn't.

His life-story is one of the most thrilling tales of adventure ever written. And it shows the miracle-keeping power of our God.

The enclosed is a clipping from an editorial in a recent issue of the daily in this city. Will you please tell me the story of the "Fall of Comstock"? I cannot believe it can warrant such a title.—A CANADIAN READER.

The Canadian newspaper article was similar to others that appeared in various parts of the United States last month, to the effect that Anthony Comstock, Secretary of the New York Society for the Suppression of Vice, was to be removed from the position of Postoffice Inspector that he had held for more than forty years. The reasons hinted at for his al-

leged removal were, of course, as has been customary in most newspaper comments on Mr. Comstock during the past generation, sharply to his discredit. As the Canadian paper editorially said: "He has been more laughed at, more anathematized, than almost any man of our times. . . Now that he has received his first real defeat it is well to pause and realize that his faults are those which invariably go with high qualities and frequently make high qualities effective. The achievements of this ruthless vice-hunter far outweigh his mistakes, and his retirement from any of the activities would be something of a public calamity, not a cause for exultation."

But, fortunately for the public, this "first real defeat" of Anthony Comstock is like many another of the "real defeats" that have been heralded as bowling him over during the past forty years; it turns out to have been the defeat of his enemies, not the defeat of Anthony.

As some of the newspapers have already announced, Mr. Comstock's official appointment as Post-office Inspector has not been revoked, and it is not likely to be. In a recent personal letter to the editor of *The Sunday School Times* he wrote:

I had a very delightful interview with the Postmaster-General and Chief Inspector at Washington yesterday, and I am still a Post-office Inspector, and expect to remain so for some time to come. I do not think there has been any change contemplated by the Chief Inspector.

Anthony Comstock hates vice, and lovers of vice hate Anthony Comstock. But he is loved by many others for the enemies he has made, and that he will continue to make as long as his invaluable life is spared to do to the death the ghastly and soul-destroying traffic against which, in the strength of God, he has for almost half a century flung himself and all his God-given resources.

The present newspaper flurry reminds one of the attempt made a few years ago to end Mr. Comstock's official activities when he had stopped a certain art organization in New York city from its promiscuous circulation of objectionable matter. In December of that year an effort was made to have him removed as Postoffice Inspector. The following account of the incident is given in his authorized biography:*

When he learned of this attempt, Mr. Comstock went on to Washington in person to see Mr. Cortelyou, then Postmaster-General. Mr. Cortelyou was sitting at his official desk when Comstock's name was brought in by an attendant. Instead of sending for his caller, the Postmaster-General arose from his desk, walked out to the reception-room, and took Mr. Comstock heartily by the hand. Walking back together to the private office they talked the matter over, and Mr. Cortelyou said:

"Mr. Comstock, I have never had a thought of not reappointing you. But you're a veteran, and I have a right to appoint you under the Civil Service rule. I am going so to appoint you, and now I am going to give you a salary whether you want one or not." Mr. Comstock had, it will be recalled, served since March 5, 1873, as an officer of the Federal Government without pay, this having been done at his own request. It is a question whether any other man living has any such record. At Mr. Cortelyou's insistence he now consented to receive a salary from the government, the first that he had ever taken. And the newspapers published the statement that the Postmaster-General had refused to reappoint Mr. Comstock!

The vindicated lover of purity has said quaintly, in comment on this experience: "You fellows who are sowing seed don't know what the rays of the sun are on the back of the weeder."

Because Anthony Comstock is alive and at work the young people in high schools and boarding-schools are prevented from receiving through the mails reading matter and pictures of a sort so vile that many readers of *The Sunday School Times* have never imagined such things could be in existence.

Because Comstock is alive and at work, decent persons on the street and in stationery stores are saved from the insult of having thrust before them unspeakably vile pictures and books that a generation ago were a common matter of sale in such places. And young men and others who are easily appealed to and dragged down by the infamy of this sort of vice traffic are saved from that attack upon their lives and souls.

His relentless and long-continued warfare against this traffic has made Mr. Comstock a mark for assassinating attempts upon reputation, character, and his physical life during all these years. But he has quietly rested upon the word of God: "No weapon that is formed against thee shall prosper; and every tongue that shall rise against thee in judgment thou shalt condemn. This is the heritage of the servants of Jehovah."

As showing his continued and successful activity, even at seventy-one years of age: Since the first of this year the New York Society has made 67 arrests, and has seized 1583 obscene books, 13,512 obscene pictures, 123 negatives for making pictures, 445 advertising circulars, 7233 articles of illicit traffic, 942 lottery schemes, 34,650 lottery tickets, and 452 lottery prizes. Some years ago his total work represented the destruction of nearly 50 tons of vile books, over 25,000 pounds of stereotype plates, 2,050,000 obscene pictures, and over 12,000 negatives.

A beautiful expression of the simple-hearted faith in God that has been Anthony Comstock's safekeeping and victory is found in the following statement of his personal experience that he once made to the Editor:

"You are in the surging billows, and all you have got to hold on to is a little thread anchoring you to the pier, and it's very frail, and you're afraid it will break. And then it does break—it is self, and you're about to go down. Just then you hear, 'Fear thou not, for I am with thee; be not dismayed, for I am thy God;' and you see a strong cable thrown out, and you lay hold on it, and feel safe again. And when your hands grow numb, and you fear that you'll have to let go, you find that some one has put it under your arms and around your body, and you cannot sink."

That is Mr. Comstock's idea of God's keeping as he has tested it.

Just a word in closing in regard to our last text. During the past winter Mrs. Root's only brother was taken away. I wrote to the sister-in-law, offering her some words of consolation, and asked her if she was clinging closer than ever to God's precious promises. She wrote back and quoted the words, "Fear not, for I am with thee; be not dismayed, for I am thy God," etc. She said she found the words in a newspaper at the very time when she needed them most; but she said she had searched her Bible in vain to find them, and asked me if I could tell her where to look. I found them in Isaiah 41, and the circumstances brought out this wonderful promise in a new and hitherto undiscovered beauty and grandeur. No wonder Anthony Comstock has "prevailed" and kept up, for he is resting his life and faith on such promises.

* Anthony Comstock, *Fighter: Some Impressions of a Lifetime of Adventure in Conflict with the Powers of Evil.* By Charles Gallaudet Trumbull. To be had from the Sunday School Times Company, 1031 Walnut Street, Philadelphia, at \$1.25 net.

Since writing the above we have received the sad news that our vehement and energetic friend has been called to his reward. We clip the following from the *Medina Sentinel*:

Anthony Comstock, the store porter who became a national figure by fighting obscene books and pictures, is dead at 71 years, after a crusade lasting 43 years. In that time he imprisoned nearly 3000 people for impairing morals, and collected nearly a quarter of a million dollars in fines.

Still later.—Today is Oct. 5, and I hold in my hand the *Menace* for Oct. 2. This paper makes mention of the death of Anthony Comstock, but, unlike the other periodicals I have come across, they severely criticise our departed friend. In fact, I should not want to put in print the things said about him—at least not in *GLEANINGS*. As an illustration of their *mistaken and unjust* statements, let me quote just one paragraph:

"All his life, after he fastened himself to the federal payroll, he was a professional blackmailer."

How does the above sound when we are told in the article from the *Sunday School Times* that Mr. Comstock absolutely refused any salary as an officer for the federal government since 1873 until finally the Postmaster-General declared he was going to give him a salary from then on, whether he wanted one or not? Now, if the *Menace* is as far from the truth in other statements—statements made without knowing the real facts in the case, how much allowance should we make for what we find on its pages? It seems that Anthony Comstock decided that the *Menace* was infringing on the Comstock law, not only once but several times. You know we are told that "the law is a terror to evil-doers."

We also give place to the following from the *Pratt New-Yorker*:

Anthony Comstock, secretary of the New York Society for the Suppression of Vice, died at his home at Summit, N. J., Sept. 21, aged 71. He was a native of Connecticut, a veteran of the Civil War, and was first aroused to his life-long fight against vice by the free dissemination of indecent literature among the young. In March, 1873, the so-called "Comstock law" was enacted by Congress, and Mr. Comstock became an inspector in the postal service. In that place he put a stop to the dissemination of obscene matter through the mails, and also to the circulation of lottery tickets, fraudulent advertisements, etc. The present efficient system of investigating and checking fraudulent transactions through the mails must be credited chiefly to him.

We close with the following, clipped from the *Sunday School Times* for Oct. 2:

Weapons, threats, physical attacks of fiendish ingenuity and effectiveness, could not intimidate him. He quietly accepted God's promise as a personal word to himself. "No weapon that is formed against thee shall prosper," and went about his business letting God prove this to the confusion of

his enemies. Neither could men appeal to covetousness in him, as they sought to do. When he was running the famous Louisiana Lottery out of New York, where it had done the flourishing business of taking in over \$5000 a day, he was offered \$25,000 a year if he would simply cease to interfere with the company's work. When he declined, they tried still more enticing bribes, the only result being that, as Joseph Cook later wrote, mortal wounds were inflicted "upon the Louisiana Lottery, and now that Devil Fish of the Gulf is in the agonies of dissolution."

We are today living in a land that is comparatively free from open traffic in things that a generation ago were making their infamous appeal to the eye and mind of school children, and of young men in business, and of older people; and this is so because Anthony Comstock lived out his life in self-surrendered and successful conflict with that evil. May God raise up others who shall fight as faithfully as he did.

A PRAYING PRESIDENT.

Some good friend has sent me a clipping from the *New York Times* which reads as follows:

"When the President arrived at the Cabinet meeting," said Bishop Anderson, "his face wore a solemn look. It was evident that serious affairs of the nation were on his mind. He said to the Cabinet members: 'I don't know whether you men believe in prayer or not. I do. Let us pray and ask the help of God.'"

"And right there the President of the United States fell upon his knees, and the members of the Cabinet did the same, and the President offered a prayer to God. While the war rages in Europe, we in this country should thank God that in this crisis of the world we have a Chief Executive who is a servant of God who stands with his hand in the hand of God. Every minister in the land should, every time he offers a prayer, take Woodrow Wilson by the hand and lead him into the presence of God, and ask that he be given strength to continue to be the great apostle of peace among men."

There was a chorus of "amens" from the ministers. Later a telegram expressing the confidence of the delegates in him was sent to the President.

May God grant that the president who shall come after President Wilson may be also a God-fearing man, and one who has faith in prayer.

THE LIE AND THE LIAR—WHAT SHALL WE DO WITH THEM?

We clip the following, by Robert E. Speer, from the *Sunday School Times*:

A nation which tells or does lies starts off foredoomed to judgment. We need to see and to drive the lie and the liar out of our national life.

Perhaps our readers will recall what I have several times mentioned, that the *Sunday School Times* says "a lie is always wrong." In another place they say "deception is always wrong." May God hasten the time when not only individuals but nations shall find out the truth of the above and accept it.

TEMPERANCE

The most dangerous trust is the liquor trust. It is a combination of gold without God, cash without character, silver without soul, and power without principle.—REV. JAMES GORDON, D.D., *Whisperer*, in *Ohio Messenger*.

THE TRUTH ABOUT THE LIQUOR BUSINESS.

Today, Oct. 22, there is such a pile of leaflets and bulletins afloat, both for and against the liquor-traffic, that it may trouble many people to separate truth from falsehood. Please bear in mind, friends, that the wets have no object in view except to gather in a little more money. They have no interest in the good of our nation and in the matter of trying to elevate poor weak infirm humanity. In our effort to set the people right, especially the people here in Ohio, I want to make three extracts from the *American Issue*; and please remember that these extracts have the indorsement of our schools, our churches, our railroad companies, our manufactories, our farming communities, and, in fact, all good and unselfish people not only here in America, but I might almost say of the whole wide world. Read this and ponder.

WHY OHIO LIQUOR MEN SAY NOTHING ABOUT THE SALOON; SALOON SO BAD IT CANNOT BE DEFENDED.

Not a word about the saloon in any of the wet literature or on any of the wet posters!

Did you know that?

Do you hear wet speakers mention the saloon at attempt to defend it?

You do not.

Why is it that the wets are silent about the fact, thing they are fighting to maintain?

Why do they talk about everything else, but so far as literature and speeches are concerned seem ignorant of the existence of the saloon?

Is there a reason for this silence?

There is.

The saloon is such a gigantic evil that its very name is distasteful to the people, and this holds good with many wets as well as with the dries.

The more attention is directed to the saloon, the more its ugly and unamerican character is revealed, and the more dry votes will be cast.

No class of men know this so well as the liquor men.

So there is a general understanding in the liquor camp that the word "saloon" is not to be used.

SOPHISTRIES OF OHIO LIQUOR MEN ANSWERED IN A FEW SENTENCES: THEIR SPOOK CLAIMS, ASSERTIONS, AND PRETENDED ARGUMENTS ARE FLIMSY AND FALSE, AND ARE EASILY DISSIPATED BY FACTS AND COMMON SENSE.

The wet official argument against prohibition speaks of Ohio liquor manufacturers "with more than 100,000 employees."

Government figures give the total number of employees of Ohio liquor manufacturers, including wage earners and male and female clerks, as 5,517.

Which is right?

I said wet advertisements and big wet campaign that under prohibition Ohio property values "aggregating \$100,000,000 would be thrown into the sea."

Government figures give the total capitalization of all the breweries, distilleries, and wineries in the state at \$64,459,024, and this includes millions of watered stock like the Hoster-Columbus Associated Breweries, which was incorporated at \$12,000,000, and paid taxes on a valuation of a little more than a million and a half.

Which is right?

"Prohibition has not settled the liquor question anywhere it has been tried," says a wet advertisement.

What about the 19 states that now have prohibition? What one of them is even considering going back into the wet column? What about Kansas, for instance, which has had prohibition for 35 years and finds it so well that last fall the wet candidates for Governor polled only 6 per cent of the total vote, while all political parties endorse the prohibition policy?

Is not prohibition the only policy that does settle the liquor question?

"Prohibition would mean the loss of \$15,000,000 in taxes to the state of Ohio and its political subdivisions," says a wet advertisement.

Not at all. Ohio plants which now manufacture beer and whisky would, as in other states, be transformed into packing-houses, ice-plants, milk-factories, and other productive institutions, employing more men and paying more taxes.

"Prohibition would increase VOTE TAXES," says a wet advertisement and the wet speakers.

Figures of the United States Census Bureau show that in prohibition states general property taxes collected average \$10.12 per capita, while in licensed states they average \$16.98 per capita.

Which will you believe—the unsupported claim of the wets or the official figures of the government?

"Prohibition takes away from you every vestige of personal rights." Quoted from a wet advertisement.

It does not. It takes away from the liquor-dealer the right by suffrance of selling poison. The United States Supreme Court says he never had an inherent right to sell the stuff. It does not take away the right to use, but to sell. You have the right to eat rotten meat, but you do not have the right to sell it.

"Prohibition would deprive thousands of workmen of the livelihood for which they have fitted themselves," says the official argument against prohibition.

A few hundred will cover the entire number of brew-masters, rectifiers, etc., in Ohio who have "fitted themselves" for special work in the liquor-traffic. The driver of a brewery-wagon can drive any other kind of wagon; the maker of beer-kegs can do any kind of cooperage work; makers of beer-bottles can make milk or any other kind of bottles.

Remember, however, that the thousands of men in Ohio who have lost their jobs through drink are down and out for good, unless prohibition comes to their rescue. Prohibition will give these men another chance.

"The state will suffer a financial panic if prohibition is adopted," says the wet argument against prohibition.

Bosh! Who ever heard of a panic resulting from stopping a waste of money? Instead of worse than wasting the \$110,000,000 now annually spent for liquor in Ohio, spend that sum in lines of legitimate trade; and instead of a panic there will follow an era of prosperity such as Ohio has never known.

"Ohio cannot afford to lose the \$6,000,000 now paid the state, county, and municipality in liquor-license fees," say the wets.

Ohio cities and towns cannot afford to lose this revenue. This license revenue equals \$1.20 for each man, woman, and child in the state. The drink bill for a year equals \$22.00 for each man, woman, and child in the state. Ohio squanders \$22.00 per capita to get in return \$1.20 per capita. She is out of pocket on this item alone \$20.80 a year for each man, woman, and child. Add to this the cost of caring for the product of the saloon, and the actual loss is at least double the sum here quoted.

"Ohio cities and towns cannot afford to lose the saloon revenue which is now applied on their taxes," says wet literature.

The more liquor revenue Ohio cities and towns receive the greater their burden of taxation and indebtedness. Cincinnati now has a bonded indebtedness of more than \$60,000,000, and a tax rate approaching the limit, and yet she receives \$400,000 a year in saloon revenue, and faces a half-million dollar fire insurance loss. Her bonded indebtedness is \$165 for each man, woman, and child. Kansas has no revenue from saloons, and her bonded indebtedness is less than 10 cents for each man, woman, and child.

"Prohibition in Ohio will lose the farmers a valuable market for their grain," says a wet advertisement.

Only about 1 per cent of the grain of the country is used in making liquor. As the dry area increases, the price of all farm products advances, because more people have more money to buy everything the farmer raises.

"Bootlegging will be encouraged and speakeasies will increase if prohibition is adopted," say wet speakers and liquor advertisements.

The annual report of the Ohio Liquor Licensing Board bears out the contention of the drys that license fosters speakeasies. That report shows that fines imposed on liquor-law violators in the 45 dry counties totaled \$14,850, and in the 43 wet counties \$41,360. The wets themselves say there are as many speakeasies in Cleveland as licensed dealers, and the saloonkeepers of that city appealed to the Governor last year to protect them from the horde of illicit sellers.

ANOTHER VERY WET ARGUMENT

The first Sunday Chicago saloons were closed, arrests for drunkenness fell from 243 to 63, while the crime record was the lowest in the city's history. There is no better evidence than this that the United States Supreme Court was right when it declared the saloon to be a source of crime and misery. Chicago's record of a closed Sunday afternoon has been mentioned by the wets in favor of the liquor traffic.

MODERATE DRINKING AND PROHIBITION.

The great argument—in fact, almost the only argument the wets try to make, after being driven into a corner all over the world, is that moderate drinking is better than downright prohibition. They are claiming at this date, Oct. 20, most vehemently, that a man can do better work, and enjoy more health, by a moderate and reasonable use of intoxicants; but the reports from our factories, railroad companies, schools, colleges, and everywhere else, are now coming like a mighty flood to prove the contrary. In fact, this great flood is daily gathering might and volume to such an extent that any use of intoxicants, even in small quantities, must and will be driven not only

from the United States, but from the whole face of the civilized world. Our magazines and periodicals of every sort, unless it is those that still hold on to their liquor advertising, are coming forward in every issue showing that intoxicants in any shape for old or young are always damaging and nothing else. Here is something that I am glad to see in the *Outlook*:

ALCOHOL AND EFFICIENCY.

One of the significant and unexpected results of the new campaign for scientific efficiency in industry is the movement against alcohol. On several occasions *The Outlook* has called attention to this movement. Now comes the report of the Methodist Temperance Society, indicating how widespread is this movement.

This society has made a careful investigation of conditions in the iron and steel trades of Pennsylvania, Ohio, Illinois, and West Virginia. It finds sixty-three large concerns that have taken steps to determine the influence of the moderate use of liquor on working efficiency. Without exception these firms testify that the effect is bad. These corporations include such firms as the Youngstown Sheet and Tube Company, the Harrisburg Pipe and Pipe Bending Company, and the Illinois Steel Company. Eighty-three of the concerns questioned, in employing and advancing men, discriminate against those who use alcohol. To quote one of them, "Even the most 'moderate' use of alcohol is fatal to a man's chance of advancement." Among these eighty-three firms are the Oliver Chilled Steel Plow Works, the American Steel and Wire Company, and the Pennsylvania Steel Company. Ten great concerns have prohibited absolutely the use of alcohol on the part of employees. Among them are the Reading Iron Company, the American Sheet and Tin Plate Company, and the Lukens Iron and Steel Company.

Under the old rule-of-thumb management this situation would never have come about. The effect of alcohol on efficiency would never have been known exactly. But when the new and supposedly infallible methods of efficiency at times failed, the resulting investigation into the cause showed that it was due to individual unfitness caused by the use of alcohol. And when it was shown that even a little alcohol—as little as might be in two glasses of beer—was the cause, the result was inevitable.

In the scientific plan of efficiency it is necessary, to use a military phrase, to hit the bull's-eye every time. A bullet in the first ring won't do. In such circumstances a workman need not be anywhere near intoxicated to be inefficient. A glass or two of beer makes the difference between a bull's-eye and a shot in the first circle.

The new plan of efficiency is so profitable to both employer and employee that whatever stands in its way must go. Economic necessity is making converts to prohibition. The Methodist Temperance Society's report shows how fast men are moving in that direction.

May God bless the Methodist Temperance Society.

Since the above was in type we find the following in the Cleveland *Daily Press*. It is an attempt of one of the "home rule" to defend the wets in the matter of efficiency.

"PROHIBITIONISTS ARE FOR EFFICIENCY."

If the laboring man drank no beer or liquor, even temperately, his efficiency would be greatly increased.

Somehow these prohibitionists are great for "efficiency." They want to make machines of men, to produce as much as possible in the shortest time

possible, *without joy*, without change, without recreation.

In the first place such a course never will increase wealth, and if it did, it would be at a tremendous cost to the living manhood of the state.

They next say that there would be no drunkards and that the sobering effect on the workman would save money now lost in drink; that the money spent in drink would be spent for groceries, etc.

Well, if every man who drinks a glass of beer were a drunkard, and had nothing left to buy groceries, there might be some point in the argument; that is, if he can use more groceries than he now eats. But the number of drunkards, unfortunate as they may be, when compared with the number of temperate drinkers, is so small that the argument falls of its own weight.

GRAHAM P. HUNT,

Counsel Ohio Home Rule Association.

In the above I have taken the liberty to put in some italics. It makes me think of the kind of joy these fellows *enjoyed* when they got home singing "We won't go home till morning." And it reminds me too of the man who, under the influence of this kind of joy(?) murdered his *blind wife* as related in our back numbers, and the other one who slashed his helpless three-year-old boy seventy times—see page 735, Sept. 1. Do we want any more of such joy? And does not the above plea for moderate drinking or for the moderate use of liquor tend to help the dry side more than the wet?

THE RIGHT TO BE BORN SOUND, WITH A SOUND MIND IN A SOUND BODY.

The following is something I furnished one of our Medina papers. As it may be interesting also to the readers of GLEANINGS we give it a place here:

An Ohio man, Mr. John J. Lantz, in an address in behalf of good government, at Minneapolis on August 22, said something as follows: "We ought to concede to our babies the right to be born sober, with a sound mind in a sound body." They have the right to be born in an environment that will not deliver them to reform institutions in early manhood and womanhood, with a guarantee against cholera and smallpox. Isn't it more important to protect our babies against alcoholism? During the past 60 years that I have lived here in Medina, I have watched quite a few babies from the cradle to the grave. I have seen them while growing in their mothers' arms, and later I have watched their toddling feet. I have had a glimpse of them occasionally as they attended our Medina schools. I have seen the boys and girls grow from childhood to manhood and womanhood. One after another I would hear of their marriages. A little later the father and mother would show me their baby. Now, it would be a pleasant thing, a *glorious* thing, if all these little ones grew up and followed in the straight and narrow path. I remember a very pretty-faced, black-eyed German girl. She used to come to my store frequently, and I got well acquainted with her. One day she said to me confidentially, "Mr. Root, I am going to get married." A little later she introduced a young man, German like herself, and said, "Mr. Root, this is my husband." Time passed; and one day when I was tired of working at the bench she came in with a bundle in her arms and said smilingly, "Mr. Root, I got a baby." Of course, I talked to the baby, and saw him frequent-

ly until he could run about, and then I lost sight of my good friend Caroline. I have never seen her since. I will tell you what I did see, however. Years ago one of the boys came running to me out of breath and said, "Mr. Root, come quick. There is a young man out here declares he's going to lie across the track when the locomotive comes and it's already whistling." I found a young man I thought I had never seen. He was beastly drunk, and declared his purpose of lying across the track. He gave as a reason that he had promised his mother never to drink another drop, and that he had repeatedly broken his promise. "Now," said he, "I am going to make it sure. It's the only way."

My good friends, the above is a sample of a drunken man's logic. Finally, I asked his mother's name. How do you think I felt when I found the boy's mother was my bright friend Caroline, of former years? I tried to go with him to his home down north of Medina; but every time I left him, as soon as I was out of sight he would get back and lie across the track; and to save his life I was obliged to sit up almost until midnight, or until all the trains had passed, before I could go home.

The above is only just one little brief sample of the work of our saloons. Shall we not, for the sake of the babies, if for no other reason, put them out of existence when we come to vote November 2?

DAILY PAPERS THAT REFUSE LIQUOR ADVERTISING.

"Godliness is profitable."

It seems the W. C. T. U. has been making investigation in regard to the attitude of the daily papers of our nation toward drink. The following is a report clipped from the *Ohio Messenger*:

LIQUOR ADVERTISING.

The present attitude of the daily newspapers of the United States toward liquor advertising and prohibition is inspiring. The investigation reached every daily newspaper in the United States. Six hundred and seventy-nine replies were received to 2160 letters. Five hundred and twenty of the daily newspapers replying reported that they accept no liquor advertising. Three hundred and sixty of them announced that they advocate national prohibition in their editorial columns, while of the remainder only 200 are willing to say that they oppose. Three hundred and sixty-nine favor state prohibition, with only 193 opposing; 397 favor local prohibition, with only 176 in opposition.

Ten years ago no one could name half a dozen daily newspapers in the United States which favored national prohibition. Generally they treated it as a joke; and it was a common plaint of the temperance people, "If we had only one great newspaper!" Today, such great dailies as the *Republican*, of Springfield, Mass.; the *Tennessean* and *Banner*, of Nashville; the *Times*, of Detroit; the *Times*, of Indianapolis; the *Journal*, of Lincoln; the *Gazette-Times* of Pittsburg; the *Intelligencer*, of Wheeling, and scores of other papers that are representative of power and influence absolutely decline liquor advertising on any terms.

When the Pittsburg *Gazette-Times* announced that it would accept no more liquor advertising one issue of the paper had two entire pages filled with fine-print paragraphic expressions of approval, and it announced that it was literally overwhelmed with its laudatory mail. The Chicago *Herald* added three thousand columns of advertising within a short time after taking its stand. The Coshocton (O.) *Trilune* gives a detailed report of wonderful prosperity under its dry policy, although they were "dead enough to drag out" when they were wet. A cheering fea-

ture of the correspondence elicited by this inquiry was the practically unanimous sentiment of the papers that prohibition is coming.

Only 46 of the papers replying were located south of Mason and Dixon's line. The rest were all Northern papers; and in view of the fact that a large majority of the Southern papers are known to be dry, the showing made is all the more imposing. The American press is no longer a guardian angel, but is a specter to the liquor interests.

FLORENCE D. RICHARD.

I wish every daily in our land, more especially the great city dailies, would take notice of the paragraph above in regard to the Chicago *Herald*; and every one who has read it knows the *Herald* came out boldly and fearlessly in no doubtful terms—a "guardian angel" no longer, but a "specter" truly to the liquor trade.

On page 871 of our last issue something is said in regard to the matter of prohibition among college students, and we made a quotation in regard to Oberlin. It seems from the following, which we clip from the *Cleveland Plain Dealer*, that the colleges of the West are not going to be behind in the matter:

FRAT HOUSES GO DRY.

CHICAGO, Oct. 14.—Resolutions forbidding liquor in chapter houses of the Beta Phi fraternity were adopted at the convention of the order today. The resolution affects chapters at twelve colleges and universities in the middle West.

INTOXICANTS IN OUR COLLEGES.

We clip the following from the *Plain Dealer*:

BARS LIQUOR AT YALE; FACULTY SAYS FRATS AND CLUBS HEREAFTER MUST BE DRY.

NEW HAVEN, Ct., Oct. 22.—Notices have been sent out by the Yale faculty to all clubs, secret so-

cieties, and fraternal organizations to which Yale undergraduates belong, informing them that after Nov. 1 they will not be allowed to serve liquor in their club, society, or fraternity houses.

The faculty order is expected to end the social drinking of undergraduates which has been excessive at times.

Action is taken in connection with a new state law which provides all clubs or similar organizations which wish to serve liquor must obtain a special license. The Yale authorities do not desire undergraduate clubs to request licenses allowing liquor to be dispensed.

May the Lord be praised for the above. But does not this notice, given so publicly, show up a rather sad state of affairs in times past? If Yale makes such a confession, how about Harvard, Princeton, and others. See page 871, Oct. 15.

BOOZE CAUSES THE LOSS OF A STEAMSHIP.

Because her crew were intoxicated, a French steamship, loaded with ammunition, on her way to Nieuport, blundered into Ostend, and was sunk by the Germans.—*American Issue*.

REVENUE—IT SOMETIMES WORKS BOTH WAYS.

The cost of feeding the prisoners in the county jail during the two years while Lansing was dry was \$5600, while during the two ensuing years of wetness the cost of feeding them (at the same rate per person) was \$11,300. Quite a difference for a town of 40,000.—*American Issue*.

ANOTHER KNOCKOUT BLOW FOR CIGARETTES.

We quote the following from the *Akron Beacon*:

NORFOLK, VA., Oct. 1.—Captain Scales, commanding the naval training-station here, has issued an order banishing cigarettes from the government reservation. He hopes by this means to make recruits strong and active.

Temperance Department continued on p. 19, advertising section.

POULTRY DEPARTMENT

THE PHILO SYSTEM UP TO THE PRESENT TIME.

Will you kindly publish what you know of the Philo system of keeping poultry? I should like to keep a few hives of bees and a few chickens, just to furnish eggs and honey for my own table.

I have a friend who keeps quite a good-sized flock on the above system, claiming that it is a paying proposition when one is cramped for room as I am. New Britain, Ct., Sept. 26. X. Y. Z.

My good friend Philo has been demonstrating that chickens can be kept and a goodly amount of eggs secured when half a dozen or more are confined in closed pens 3 x 6. But the result very much depends on how much care is given them. They must have animal food in some shape as well as a variety of grains, and they must have, too, green food daily, or almost daily, or some substitute in the way of cooked or soaked alfalfa meal or red clover. Under

some circumstances, with loving care, the amount of eggs secured may be almost as great as if the fowls had a run outdoors. But the expense of food will be very much more, and the expense in the way of care, etc., if one counts his time worth anything. Huber has had six hens all summer in one of the little Philo coops; and he says that, before they began to moult, he thinks they averaged pretty nearly three eggs a day. This we should call a 50 per cent yield—three eggs from six hens. Now, if you could have a yard also where they could dig and scratch, say only 3 x 6 feet, it would be very much better, because you could bury some oats in this little yard, and let them dig them out. Our Ohio experiment station has made a test of fowls confined, and fowls running at large. I have not the figures now before me; but if I recollect

right, the hens with a good large yard laid about a third more eggs than those shut up in a small house. If you had a yard large enough so they could get green food and insects more or less, the expense for the grain might be reduced a third or perhaps a half. In our Florida home 100 fowls, young and old, had a run of three acres; and they get all over it every day or two.

One objection that has been made to the Philo system is that it seems cruel to keep fowls shut up in this way, as it is so natural for them to range at large; and where they have been in the habit of running loose, it *does* seem to be a hardship. But chickens

that have been shut up all their lives do not seem to mind it very much. While visiting Philo at his home in New York I said, "But wouldn't they *enjoy* it if they could once get out?"

By way of reply he opened one of the little coops, but none of the fowls ran out at all. Then he took two and tossed them out into the garden; but to my great surprise they ran right back into the coop. They did not feel at *home* outside. There is a difference in the breed, however. Some stand confinement very much better than others. Leghorns do not seem to be very well adapted to confinement.

HEALTH NOTES

And Jesus said unto them, This kind can come forth by nothing but by prayer and fasting.—MARK 9:29.

Dear Brother Root:—After reading your Health Notes, Oct. 1, I am prompted to ask you, as a follower of the Great Physician, why you never give the injunction that he gave his disciples in Mark 9:29 in curing difficult diseases. I have found fasting for a period of 36 to 40 hours, from all food, and even drink unless thirsty, when water is taken as often as desired, to be an unfailing specific for cough, colds, and the disposition to catch cold, catarrh, and ills of throat and nasal passages, and cure for deafness where the actual physical injury through inflammation has not been so great as to carry away some essential part of the "machinery," as you term it, of hearing.

In breaking your fast, eat as heartily as your appetite prompts of the easiest *uncooked* food to digest, which I have found to be a salad made of lettuce, celery, cucumber, cabbage, endive, or even turnips, any two of which, according to season, may be chopped up with raw apples or tomatoes, and dressed with a good salad oil and salt; and, if desired, a dash of lemon juice and honey.

For bread, chew slowly along with the salad some good hard biscuit, like hardtack, German pretzels, Swedish knackbrod, or water crackers. This is for your *breakfast*. Give the hearty meat dinner the *next* ~~morning~~—abstain from "meats offered to the idol" of one's belly, from pork, and from eggs. It has been said that no orthodox Jew who abstains from pork ever dies of cancer.

Your directions as to a daily washing of the whole body are good with one exception—that of the toothbrush. Your teeth and mouth will become *absolutely clean*, as soon as the alimentary canal has through systematic fasting, becomes clean. This cleanliness is indicated by the fact that the excreta becomes inoffensive in odor, and of a healthy yellow color.

If the teeth are unclean, with a bad taste in the mouth, it is a sure indication that the forty-hour fast should be resorted to at once and persisted in from time to time until this ideal condition of a clean mouth and alimentary canal becomes a settled condition, when the buzzing sounds in one's ears, with sore eyes, running noses, cough, colds, eczema, and so on, will "lift up their tents, like the Arabs, and silently steal away" without recourse to pills, gargles, washes, etc.

However, I have found it impossible to attain this ideal while keeping to three meals a day of cooked

food. One meal is better by far than three; and your idea of the apple supper is excellent. I find a vegetable diet, composed of half alkaline vegetables and half acid fruit the ideal thing, though I vary it with small quantities of the dairy products, good butter and cheese; but milk, almost never. Honey in the comb is enjoyed by me as a nectar from God.

The further along I go on the road to Wellville the further behind I leave meat and eggs, which I have identified as "meats offered unto idols."

JOHN A. WINTERBURN.

West Morris, Ct., Oct. 8.

My good brother, I agree with you in regard to the matter of prayer and fasting. Faith healing has had at different times many followers, and has, even at the present time; but I shall have to confess that I never noticed, until you called my attention to it, that the Savior recommended in a single sentence *fasting* as well as *prayer*; and I am sure my health has been very much benefited since I have used no *cooked* food, after noon time. Apples are certainly uncooked food, and the little cheese I use with them is uncooked in the sense that no cooking or heat is necessary for the last meal of the day. Mrs. Root often declares it is quite a saving of housework to be relieved entirely of the task of "getting supper." I personally, however, could not quite agree in regard to the vegetarian diet. Please remember I was for four years myself a vegetarian; and later on I was for *eighteen weeks* without any vegetable food whatever—lean meat and nothing else—not even an apple. I now use a little meat, but get along very well most of the time, even for several days, without any meat at all; and I think very likely I could adopt a vegetable diet exclusively, providing I could have plenty of milk and eggs. If I understand you correctly, you object to milk. I use milk both at breakfast and dinner, but only about half a cupful. If I take more I

sometimes find it necessary to stop the use of milk for several days. Your statement that no toothbrush would be needed if we fast often enough, etc., may be true. Of this I feel sure, that the mouth tastes bad, and the teeth become coated, much oftener when there is a disturbance in the digestive machinery.

HIGH COST OF LIVING: \$27 A BUSHEL FOR WHEAT, ETC.

I have said so much about making your own breakfast foods with a little hand mill, or boiling your wheat and other grains whole, that it may be a little wearisome. Here is something, however, from *Farming Business* that may wake some of us up in regard to the one chief cause of the high cost of living.

ONE CHIEF CAUSE.

Pampered palates form one of the chief causes of the high cost of living which has been causing so much worry to millions of people in this country alone. When wheat went to a dollar a bushel and beyond, professional paragraphers began to use up much good ink in claiming that the farmers, and the price they were getting for their wheat, were the chief cause for the high cost of living. Had they looked into the tin cans and paper sacks which contained a goodly portion of the food which they ate they would have seen a much greater factor than the price which the producer gets, and that is the price which the middleman and the handler get.

Simply for the sake of making the argument as simple as possible, let us take one thing for example, a thing which is found on the breakfast tables of so many people in this country—prepared breakfast foods. Professor E. F. Ladd, of the North Dakota Experiment Station, throws a revealing light on this subject of the cost of prepared cereals. When he bought a package of a widely used prepared wheat food the dealer informed him that the price had been advanced from 10 to 15 cents on account of the war. By making a simple calculation he found that when he ate it he was eating wheat at 45 cents a pound, or \$27 a bushel.

Many of our pioneer ancestors ate simply boiled wheat as a cereal food. It was very palatable and nutritious—even more so than most of the fancy cereal foods we get in waxed bags inside pasteboard cartons at a price of \$27 a bushel for the wheat from which they are made. Moreover, they had to work their teeth and their digestive apparatus more to handle the boiled wheat than we have to work ours to eat and digest these patent predigested foods of our day, and for that reason they were healthier than we are.

FRAUDULENT PATENT MEDICINES.

May the Lord be praised that our Department of Agriculture has seen fit to take hold of the medicine business and destroy their senseless drugs and punish the offenders. We clip from quite a lengthy article in the *Weekly News Letter*, Washington, D. C., the following:

It is pointed out that traffic in medicines for which false and fraudulent claims are made is not only an economic fraud of the worst kind in that

a worthless preparation that costs but a few cents is frequently sold for a dollar or more a bottle, but that health and even life are endangered by failure to secure the service of a physician in such serious diseases as tuberculosis, diphtheria, pneumonia, and scarlet fever until too late, because reliance may have been placed in the curative powers of some worthless preparation which is claimed to be a never-failing remedy. The deluded victim may not realize his danger until the disease has reached a stage too far advanced for even the ablest physician to cope with it. Effective treatment depends in most cases on applying it during the early stages of the disease.

After the above quotation a list of about sixty different medicines, some of them having quite a large sale, are mentioned as being suppressed. One great harm that these medicines do, as suggested, is that, even if the medicines are harmless, they induce people to defer consulting the family doctor until it is, perhaps, too late.

This *Weekly News Letter* from the Department of Agriculture is sent to periodicals, colleges, etc., with the understanding that our different agricultural papers shall send out warnings, making clippings, etc.

OXYDONOR AND ELECTROPOISE

One of our friends sends us the following which he clips from the *New York American*:

FRAUD ORDER AGAINST NEW YORK DOCTOR.

WASHINGTON, Oct. 16.—The Postoffice Department today issued a fraud order against Dr. Herschel Sanche, of New York, and the Oxydonor Sales Company, of Rochester, N. Y., Cleveland, Detroit, and Chicago. The order alleges that Dr. Sanche controls the company, which sells a pump guaranteed to transmit hydrogen into the human system with great curative powers. Postoffice Department officials charge that the scheme is a fraud. Dr. Sanche is alleged to have made \$1,000,000 from the sale of the pumps.

Did you ever? The reporter calls the humbug toy a *pump*; and then he says it is guaranteed to generate *hydrogen*. Well, it is probably just as well that way, and just as true. The world can rejoice that Dr. Sanche has come to a stopping-place. Years ago, when the venders of electropoise got to raking in the money, Sanche and some others as covetous got up a thing and called it oxydonor; then various other parties went into it also, all claiming they could "pump" oxygen through a wire, and that is why "oxy" is put before all their make-believe traps. The writer who sends us the clipping says his wife had an aunt who was persuaded to buy an oxydonor to cure cancer. She of course died in spite of the "treatment." If it is true that Dr. Sanche has "robbed sick people" to the extent of a million dollars, he can well afford to "let up" a while.

HIGH-PRESSURE GARDENING

SWEET CLOVER—SOWING IT IN ROWS, AND CULTIVATING IT LIKE CORN.

We are today, Oct. 4, cutting our corn; and the sweet clover seeded between the rows of corn that I have several times mentioned is now a thing of beauty. There is not a bare spot in the field, and the clover is almost knee-high. There is one objection to this method; and that is, the corn, as fast as it is cut, must be carried off out of the field or a great lot of the clover will be injured or destroyed where the corn was cut and shocked. As our field is rather long and narrow, the cutters, as they cut the corn, carry it out at the sides and ends. It is somewhat expensive; but I am so anxious to see this field of clover do its best that we are risking the extra expense. Now, here is something queer from *Field Sense*, published by the Field Seed Co., of Shendoah, Iowa:

SWEET CLOVER IN MONTANA.

You remember last spring I told you about a man up in Montana, right next to the Canada line, who was growing alfalfa in rows and using 5 ounces of seed to the acre. This is the same man, but this isn't alfalfa. This is sweet clover. He grows it in rows the same way, using less than 1 lb. of seed per acre, and cultivating it like corn. He grows the alfalfa the same way, but in the pictures he sent me it had fallen down across the rows till you could not tell where the rows were, and it looked like an ordinary flat field of alfalfa. He grows Grimm exclusively, and expects to cut his whole 130 acres for seed.

You will notice from the above that it is a tremendous saving of seed. In our corn-field we used toward 15 lbs. of hulled seed to the acre. I now feel sure that half as much or even less would have done just as well, especially with the new scarified seed, and, in fact, *every* seed seems to have come up within three or four days. Perhaps if the clover is grown for feed there is an advantage in thick seeding. My impression is, we get almost as much seed from the sweet-clover plant where put in only as thick as hills of corn. When it comes to cutting it for hay, no doubt the thick seeding would be better. Who can tell us about this? As the hulled seed is worth now from 20 to 25 cts. per lb., taking only one pound in place of 15 would go pretty well toward covering the cost of running the cultivator between the rows.

SWEET CLOVER FOR BRINGING UP THE CONDITION OF THE SOIL, ETC.

I clip the following from the *Alfalfa Journal*:

On a recent automobile trip the farmers near Bloomington, Ill., visited the large sweet-clover field

on the Homer Hull farm. Fourteen acres of sweet clover were seeded with oats last year. This was not standing over a foot high. Mr. Hull seeded forty acres of red clover in the oats last year, and failed to get a stand. This seems to be a common result in this vicinity during the past few years, and that is why so much sweet clover has been planted. Sweet clover is being used in the rotation. The first crop is cut and allowed to lie on the ground for fertilizer. The second crop is used for seed production. The straw will be hauled back on the land. It is estimated that the first cutting and the straw will amount to eight tons of manure to the acre, besides the good condition in which the soil is put by the use of this method. Sweet clover seems to make a better top and root growth than red clover, and the farmers in this vicinity are beginning to think that they can depend on the sweet clover more than the old-fashioned kind.

Just think of it, friends! equal to eight tons of manure to the acre to benefit the land while you get a crop of seed besides. Our own experiments would indicate the above as being not far from right.

THE DASHEEN BUSINESS IN FLORIDA AT THE PRESENT TIME.

The following was sent us without any indication as to what paper it was taken from:

FLOUR FROM DASHEENS; FLORIDA FINDS A NEW BREAKFAST FOOD.

CRYSTAL SPRINGS, FLA., Sept. 17.—A manufactured products of dasheens is being used here, and perhaps elsewhere, as a breakfast food, and people who have tried it with the usual breakfast-food trimmings say that it is about the smoothest article in that line imaginable. Dasheens have a flavor suggesting chestnuts, and the breakfast food manufactured from dasheens is said to have a delightful nutty flavor that makes friends of the eater right away.

This information was brought out at a meeting of dasheen-growers for the purpose of considering the advisability of installing a small flour-mill for the manufacture of dasheen flour and other products.

At the meeting a letter was read from Prof. R. A. Young, of the Bureau of Plant Industry, United States Department of Agriculture. Mr. Young was in charge of the dasheen-growing experiments for the agricultural department at Brooksville a few years ago, and has visited Crystal Springs twice in the interests of that industry.

THE STRIPED SQUASH-BUG; HOW THEY MANAGE WHERE THEY GROW CUCUMBERS FOR THE GREAT PICKLE-FACTORIES.

If Mr. Root will dust his squash and pickle plants after every rain with tobacco dust and lime, half and half, he will find it a sure remedy for the striped bugs. We grow cucumbers for the Hinze pickle-factory, and we all use the remedy here.

Bowling Green, O., Aug. 23. U. E. Loy.

Very likely the above will answer, or at least help; but when it rains every day, or even every other day, it will not only take quite a little "dust," but keep one busy.

Gleanings in Bee Culture

BEEKEEPING

By Dr. E. F. PHILLIPS

One of the best bee-books that has been written in this decade.

See the editorial review on page 834, October 15.

Regular price \$2.00; or clubbed with "Gleanings in Bee Culture," one year, for \$2.50; or with our "A B C and X Y Z of Bee Culture," \$3.50.

Canadian Postage, 30c extra; Foreign Postage, 60c extra

One would naturally suppose that its author, a scientific man—a trained entomologist, and one who is constantly associated with some of the best scientists of the Government—would turn out a book that would be so technically scientific that it would be beyond the reach of the average beekeeper. This is not the case. While it is scientific, it is couched in such language and style that the average reader can easily understand it. But when we say it is scientific, we might, without further qualification, convey the impression that it is not also practical. As a matter of fact, the book is intensely so, because Dr. Phillips has traveled all over the United States, mingling with the best beemen in the country, and he has had, during several years back, one of the best beekeepers in the country, Mr. George F. Demuth, as his first assistant.

EDITORIALS

The Ohio State Convention at Akron, Nov. 26, 27

A SPLENDID program is in preparation, and a number of speakers from various parts of the state, including Dr. E. F. Phillips, of Washington, D. C., will be present. Indications go to show that this will probably be the best convention we have ever held.

Mr. A. J. Halter, of Akron, writes: "I have made arrangements at Garfield Hotel for visitors for convention, Nov. 26 and 27. Rates \$1.00 per day for single rooms, \$1.50 with bath, or \$1.50 per double room."

Of course the Root forces will be present, and some have expressed a desire to go, after the convention, from Akron to Medina in automobiles to visit the Root plant. If the roads are good the trip can be very easily made, as Medina is only 20 miles west of Akron. Visitors are always welcome at Medina.

Akron is the rubber city of the world. It makes more automobile tires and rubber specialties than all the rest of the United States put together, and it possibly equals the output of all the rest of the world. We understand an opportunity will be given to the Ohio beekeepers to go through one of the biggest plants at the close of one of the sessions.

Motor-cycle Accident to one of the Men Formerly Connected with The A. I. Root Company's Apiaries

REV. GEO. W. PHILLIPS, formerly of Jamaica, B. W. I., and later foreman of the apiaries of the A. I. Root Company, author of "Modern Queen-rearing," and the A. I. Root Company's Correspondence Course in Beekeeping, met with a severe motor-cycle accident from which he nearly lost his life. He suffered a fractured skull, a broken arm, and a shattered kneecap. However, he is now on the rapid road to recovery, and perhaps the only permanent injury will be a stiff knee.

Mr. Phillips, after he left Medina, took

a college course, and later a seminary course, graduating with high honors. He has been connected with various large churches, and is now pastor of the First Baptist Church, Hamilton, Ohio. He not only can preach Christ, but he can talk bees. Besides his long experience in managing our series of yards and raising queens in small baby nuclei at Medina, he owned and operated several large apiaries in Jamaica before he came to this country.

Right Church, but Wrong Pew

Two recipes, pages 812 and 813, Oct. 1, got separated. Some one may be following a recipe for pudding sauce and expecting it to turn out fruit cookies.

The last recipe in the first column, page 812, entitled "Cookies," should be followed by the third recipe in the first column, page 813, which has no title, but reads as follows: "Fruit cookies are made in the same way," etc.

The completed recipe should read as follows:

COOKIES.

One cup extracted honey; one cup light-brown sugar; 2 eggs well beaten; a level tablespoonful of soda dissolved in 3 tablespoonfuls of vinegar; pinch of salt; flour to stiffen (about 3 cupfuls in this altitude). Mix at night, and bake in the morning.

Fruit cookies are made the same as the above by adding one cup of shortening, one cup of chopped raisins; $\frac{1}{4}$ teaspoonful of cinnamon and allspice; $\frac{1}{8}$ teaspoonful cloves and nutmeg; cream sugar and shortening, and proceed as above.

Colo, Iowa.

MRS. OSCAR TRIPP.

The Insects' Homer

At Avignon, in southern France, Henri Fabre recently died at the age of ninety-two. Probably not one beekeeper in ten ever studied Henri Fabre, yet he was one of the very few most learned entomologists in the world, a member of the small and obscure group of men who have given their lives to the study of insects, and to the study of the honeybee among the rest.

He pursued his investigations under great

difficulties. With the responsibilities of a large family to meet he was forced to give almost his whole time to teaching mathematics, reserving only odd moments for entomology. Notwithstanding his hardships, he early became an authority in his chosen work, and formed friendships with such men as Charles Darwin and Victor Hugo. It was Hugo who called him "the insects' Homer" on account of his literary ability.

His greatest work, "Souvenirs Entomologiques," contains many valuable observations on the ways of honeybees, and has placed him among the authorities in apiculture. In an editorial on Henri Fabre, *The Outlook* says that it was through conversation with him that Maurice Maeterlinck was inspired to write "The Life of the Bee." Of him Maeterlinck himself wrote, "He is one of the most profound scholars, purest writers, and finest poets of the century just passed."

Bees Blamed Again for the Work of the Birds

A WOMAN living near one of our out-apiaries telephoned to us about the middle of October, inquiring if there was any way that she could keep the bees away from her grapes. She said that they were simply spoiling the crop. We asked if she hadn't seen birds around the grapes, and she said that she had, but didn't think that they were eating the grapes. We asked her to tell what kinds of birds she had seen, and she said they looked like small sparrows. There are a number of birds that eat grapes, and we believe sparrows have been caught in the act.

It so happened, however, that, just before this woman telephoned to us, a farmer living near Medina sent in two birds that he shot while in the very act of puncturing his grapes. He did not know what kind of birds they were, and was anxious to have them identified. A local ornithologist examined them, and showed us that they were Cape May warblers. We, therefore, explained to the woman mentioned above that in all probability the birds were Cape May warblers—that they merely punctured the grapes and the bees afterward sucked the skins dry. We told her that bees could not puncture sound fruit, and explained why they could not. She then said she had wondered why the bees paid no attention to the grapes under the roof of their porch where the birds did not come, but worked only on those outside the roof where she had seen the birds frequently.

The Cape May warblers are notorious

grape-eaters. Unless they are watched closely, however, they cannot be caught in the act, for they merely pierce the skin, making a very slight puncture, and then go to another grape. The bees, meanwhile, sucking the juices out of the fruit already spoiled, nearly always get the blame. As has been proven many times, bees will pay no attention to sound fruit. If the skin is pierced by even a fine needle, however, the bees will "get busy."

The warblers, contrary to what might be expected from their name, do not sing much. They have merely a sort of short chirrup.

The birds at this time of the year were on their way south. They winter even as far south as Central America, and in the spring migrate as far north as Canada. They remain in the north-central states a week or more in the spring on their way north, and perhaps the same length of time in the fall on their way south. It is on their southern trip that they do the most damage to the grapes, for a whole flock of them sometimes almost takes possession of a vineyard. The only remedy is to use the shotgun and thus kill and frighten them away.

The following very complete description is from "Birds of Eastern North America," by Frank M. Chapman:

Dendroica tigrina, Cape May warbler. Adult male, crown black, slightly tipped with greenish; *ear-coverts rufous*, bounded behind by a large yellow patch on the side of the neck; back olive-green, broadly streaked with black; rump yellow or greenish yellow; a large white patch on the wing-coverts; outer tail feathers with a large white patch on their inner webs, near the tip; under parts yellow, heavily streaked with black; lower belly and under tail-coverts whitish. Adult female, upper parts grayish olive-green; rump yellowish; a yellow line over the eye; middle wing-coverts with narrow white tips; outer tail-feathers with a white patch on their inner webs near the tip; under parts yellow, streaked with black; belly and under tail-coverts whiter. Immature male resembles the female, but the wing-coverts have more white. Immature female is similar to adult female, but with little or no yellow on the under parts. L., 5.00; W., 2.61; T., 1.88; B. from N., 30.

Range.—Eastern North America; breeds from Northern New England north to Hudson Bay; winters in the tropics.

Washington, sometimes very common, usually uncommon T. V.,* May 5 to 20; Aug. 25 to Oct. 7. Sing Sing, tolerably common T. V., Aug. 20 to Oct. 1. Cambridge, rare T. V., May 15 to 25; Aug. 25 to Sept. 15.

Nest, partially pensive, of twigs and grass fastened with spiders' webbing, lined with horsehair on a low branch of a small tree in pasture or open woodland. *Eggs*, three to four, dull white or buffy, slightly speckled, and wreathed around the larger end with spots of brown and lilac, .70 by .50 (Chamberlain).

* Transient visitant. These warblers are very useful visitors in orchards. A flock of warblers is said to be worth several barrels of spraying emulsion in getting rid of grubs and insects.—ED.

Our Cover Picture

OUR cover page this issue is from far-off Australia. In that country they have recently begun to realize the immense value of water for irrigation purposes. Back a few hundred miles from the coast of New South Wales there are millions of acres of intensely fertile land which, under normal conditions of from five to eight inches rainfall per annum produce only a few blades of not too succulent grass, sufficient, perhaps, for keeping a sheep alive on each five acres of land.

The illustration shows an immense reservoir that has been made away up in the hills, impounding quite a small lake, and this water has been led out on to the plains, a distance of 430 miles away.

The land watered has been re-purchased by the government, and is let out to settlers at a comparatively low rental. Although only three years since the water has been applied quite a change has come over the country. Alfalfa hay yields seven cuttings per annum, and with that sheep and cattle are fed and fattened in considerable number per acre. Fruit trees show marvelous growth, and to help dispose of the crops large canning and drying works and a very fine butter-factory have been established.

Quite a large village or shopping center is forming. Several churches have been built, and public schools established.

Several beekeepers have located on the Murrumbidgee Irrigation Area, as it is called, and no doubt they will get good results before long. The picture has been supplied to us by Mr. Herbert J. Rumsey, of Dundas, N. S. W., who has recently paid us a visit at Medina.

Insure your Product's Reputation

THE extent to which the courts go in protecting one's rights to the use of his own name as a business asset is shown in several recent trade-mark suits. "But are we interested in trade-marks?" inquires a beekeeper. You are. No large business in honey or in any other product can be built up without some distinguishing name of the product, and once a profitable business is established unfair competition may arise, involving trade-mark difficulties.

One can protect his name pretty fully, even though some one else of the same name is engaged in the same business, writes Mr. C. J. Williamson, the well-known patent attorney of Washington, D. C. A producer can defend it to the extent of requiring a competitor to use initials or full name to

distinguish the competitor's product from his own, and can sometimes even force his competitor to use some sentence pointing out the distinction.

The immense amount of litigation over trade-marks simply shows how great is their value to the producer. Among the business principles familiar to large producers of other foods and of value to honey producers as well, not the least of these is the subject of trade-marks.

Winter Packing in Rows vs. Packing in Quadruple Winter Cases

THE method of packing as illustrated and described by R. C. Gifford in this issue, page 929, has been used to a considerable extent. It is so old that probably no one can claim priority in its use. But even if it is old, it has some good features. It has the advantage over the four-in-a-case scheme (1) in that it is much more economical; (2) that the entrances of the hives can face the direction where there is the least wind exposure. This last feature is a very important one. Where the hives are packed four in a case, back to back and side to side, it naturally follows that one pair of hives must have entrances directly opposite the entrances of the other pair. If one pair faces south, the other pair faces north, and that is very bad; so it is usually recommended to place the entrances facing east and west. In most localities strong heavy winds come from the west, and fitful storms from the east. Taking everything into consideration, a southern exposure is the most favorable, and this can be permitted only when the hives are packed as described by our correspondent on page 929. But the arrangement has the slight disadvantage that the back ends of the hives are not protected like the back ends of hives in a quadruple case. In the last named there is only one side and one front next to the packing; and the packing is next to the weather, and, what is of considerable importance, the grouping of the four hives together concentrates and conserves the heat. In the plan spoken of by R. C. Gifford there are two ends that are exposed to the weather. In the case of the inner hives in the row the advantage would be slightly in favor of the long-row packing except for the conservation of heat in the four. Another disadvantage of the long case is that the bees must be unpacked earlier than in the quadruple case.

But the most serious disadvantage, according to a number of reports, is the drifting of the bees from one entrance to

another on good fly days. The stronger colonies in the row will draw from the weaker. When the weather is favorable, the flying bees in the air are inclined to join the procession where there are the most bees flying, and they will be in front of the strongest colonies, of course. The result is, the stronger grow stronger at the expense of the weaker.

The same thing can occur where the hives are packed in groups of four; but to a very much less extent because there are only two colonies on one side and the bees of either are not as likely to get confused as they are when there are a dozen entrances side by side. Dr. C. C. Miller says when colonies are put in pairs bees don't drift much. If this is true, the quadruple scheme is much superior.

This is a fruitful theme for discussion, and we should like to have those of our subscribers who have tried the two methods tell us about them; or if you have tried only the long-row scheme of packing, tell us of the objections, if any, that exist against the plan.

That New or Old Bee Disease; More Data Needed

ON page 784, Oct. 1, we said something about the new disease or malady that has been so destructive to colonies in the West and extreme Northwest. We learned of its active operations in and about Portland, Oregon. We have had considerable correspondence with Mr. E. G. Ladd, of the Portland Seed Co., who observes, among other things, that weather conditions are an important factor, and that some colonies are more immune than others to the ravages of the disease. In answer to a recent letter in reply to one from us Mr. Ladd makes some observations concerning *Nosema apis*, or bee paralysis, or both, that are worth placing before the public. He writes:

Mr. Root:—Your conclusion that the bees in some colonies were affected more than the bees in others admits of no argument; neither does the question of weather conditions being responsible for it, as undoubtedly the trouble disappears when good weather conditions prevail. Whether the sick bees recover, we are not prepared to say, but believe not. I am inclined to think affected bees disappear and die.

Sulphur is one of the best known fungicides, and colonies treated with sulphur were cured or the trouble was checked; but in no instance was a colony saved that was treated with sulphur. Although apparently cured, they dwindled away. The application of sulphur killed the brood, and the bees were a sickly lot, and supposedly became discouraged and quit trying.

My garden record this summer shows potatoes and tomatoes blighting badly. They were sprayed with Bordeaux, but there was not sufficient to go

around, and part of them were not sprayed. Weather conditions turned warm and bright, and immediately the blight was checked, and the unsprayed lot gave as fine a crop as ever grew, and no difference was discernible between the sprayed and the unsprayed.

I find by the bee record that the date of improvement in garden corresponded with date of improvement in bees; but no bee was ever, as far as I know, seen on a potato or tomato, and I do not know if they visit the blossoms or not. The remarkable feature of the whole business is that locality apparently had nothing to do with it. Bees in the mountains, in high altitudes, were stricken, as were those in the valley. Bees protected from the weather were no more free than those exposed; but, as one good old lady remarked, "It just beats all how them bees do die."

Let us hope that there will be no recurrence, and that it will not be necessary for Dr. Phillips to visit any section looking for a cause of this affliction, and sincerely hope no more such reports will be offered by yours.

PORTLAND SEED CO.,
per Ladd.

Portland, Ore., Nov. 3.

We should like to get a list of symptoms from other parties who have suffered from this disease, for the purpose of comparison. One thing we wish to determine is whether it is the old bee paralysis, or nameless bee disease, of former days, or *Nosema apis* of these latter days. If it is not paralysis, in what respect does it differ from it, and in what other respects is it similar? The more data we can get together just after an epidemic of this disease in this country, the better able we shall be to learn what it is.

In this connection we may add that some colonies or some strains, rather, are more immune to bee paralysis than others. This fact has been proved beyond question in Australia, where bee paralysis was so epidemic and destructive that the beekeepers there, as a last resort, selected colonies that were more immune than others. By a continual selection they finally secured strains that were entirely immune. Later on, Mr. R. E. Beuhne, of Tooberac, Australia, introduced some other strains of Italians from Europe and America. These immediately fell victims to bee paralysis. It was only after he had weeded out all traces of introduced strains that he was able to bring the disease under control. Mr. Beuhne is one of the most careful observers of bee life in the world.

Now, then, what we should like to determine is whether the bee paralysis of Australia and of the southern United States is the same as the *Nosema apis* of Great Britain. Is it the same as that disease or malady, whatever it is, that has been working such havoc in some western apiaries in the northwest part of the country, in and about Portland, Oregon? What relation has humidity or much rainfall to the recurrence and virulence of the disease?

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

"LIGHT honey does not impart any appreciable flavor," p. 799. Generally that's true—not always. I've had light honey (alfalfa) with so strong a flavor that I couldn't use it in my drink. [It would be more correct to say that light honey

does not impart any strong flavor as a rule. All light honeys, with perhaps one or two exceptions, have a very delightful flavor. Generally speaking, mildness or strength of the flavor varies according to lightness or darkness of the honey.—Ed.]

"THE great trouble with the 'baits' is that they granulate almost immediately after they leave the producer's hands," p. 831. Why? Because of granules in the cells from the honey previously contained. If the baits are cleaned out in the fall *by the bees*, honey should not granulate in them more quickly than in other sections. [You are doubtless correct; but a great majority of those who use baits leave the honey in. Old honey will granulate more readily than new, and when the new honey is piled on the old it all granulates.—Ed.]

REPLYING to P. C. Chadwick, p. 837, I saw once, and only once, a laying worker in the act of flying. She was in a worker-cell, and her wings were pushed up about her neck in an uncomfortable way. I think that accounts for the fact that laying workers prefer queen-cells and drone-cells. As to whether only one laying worker or many, some years ago a German investigator dissected a number of workers in a laying-worker colony, and found eggs in a large proportion. [The obstruction of the wings also explains why very often laying-worker eggs are partly up from the bottom and on the sides of the cells.—Ed.]

ALUMINUM is recommended for hive-covers, p. 818. Wonder how it compares with zinc. After years of use my zinc covers seem as good as new—no paint, no rust. [The objection to aluminum would be the expense; but, say, do you know that both aluminum and zinc have more than doubled since the war began? When the new bee-supply catalog comes out an extra charge will have to be made for zinc covers as well as for any metal cover. Why not use paper? A good quality of roofing-paper, well painted, if carefully handled, will last nearly as long as zinc; but it will never do to pile hive-supers on paper covers.

G. M. DOOLITTLE says, p. 839, "from years of experimenting along that line I

cannot help thinking that much honey is lost in the attempt to stop prime swarming by destroying queen-cells." I have not merely experimented but practiced it to the fullest extent for very many years, friend Doolittle, so that my experience is probably much larger than yours, and I am confident that I have gained honey by it in some cases, and I doubt if I ever lost by it. My best yields are generally from those colonies that never start a queen-cell, and the next best from those that were prevented from swarming by having their cells killed. But the beginner who thinks he can prevent all swarming by killing cells is fooled. [This is an interesting piece of testimony. We desire to inquire whether others have had a similar experience. We should naturally incline toward the opinion of Dr. Miller, for the simple reason that some of the best comb-honey producers in the world practice cell-killing.—Ed.]

MR. EDITOR, you say, p. 835, "We fail to see yet why piping and quaking cannot be made by the same organs and in the same way." I never hinted that they couldn't. But that doesn't make them alike. When I say, "Tom shot John," I use the same organs and in the same way as when I say, "John shot Tom," but the two things are not the same. Compare these two lines:

I can hardly imagine that shutting a cell would make the first like the second. You say the noise is made by the wings. Cheshire says, p. 157, "It is certain, also, that the wings are not concerned in its production, since queens clipped so vigorously that not a vestige of wing remains can be as noisy as others." He thinks it is "an effect of stridulation resembling that of the ant." He agrees with you that enclosure in a cell accounts for the difference. But he is apparently ignorant of the difference in length of tones, as he makes no mention of it. [It is hard to say what the effect of too close confinement would be upon the noise made by an organ located just below the base of the wings. While the wings may not make the noise, they invariably vibrate when the sound is made. Moses Quinby, in his original book which we are just now reprinting, says: "The queen was near the glass, appeared agitated, stopping occasionally to vibrate her wings, which was simultaneous with the piping, and seemed to make it."—Ed.]

J. E. Crane

SIFTINGS

Middlebury, Vt.

G. M. Doolittle tells us, page 796, Oct. 1, that after much experimenting he prefers to space frames $1\frac{1}{2}$ inches from center to center. The same here, and we have used them so for the last thirty or forty years.

There are some unpleasant things about inspection work; but it is by no means *all* unpleasant. There are some very pleasant things, and the making of some charming acquaintances and forming some lifelong friendships are not the least of them.

Mr. Chadwick calls attention on page 703, Sept. 1, to the wide difference in the price a certain consumer paid for peaches and what the producer received. There is evidently something wrong in our methods of the distribution of farm produce.

I began to wonder, as I looked over GLEANINGS for Oct. 1, whether there would be any extra copies to be had, and felt quite relieved when I found that several thousand extra had been printed. They will doubtless all be wanted, as well as a good deal of extra honey to go with them.

On pages 663 and 664, Aug. 15, Mr. Powder gives some good advice about selling honey. Advertising in newspapers, he tells us, has always been a failure with him. Getting bottled goods into wholesale houses has been his best method for this class of goods. Same here.

The statement of Mr. T. Rayment, page 711, Sept. 1, in regard to the loss of pollen while working a certain variety of eucalyptus, reducing a strong colony to a mere nucleus, is of great value. The substitute of the white of an egg stirred into pulverized sugar, he tells us further, is the best substitute for natural pollen—a fact many of us are interested in knowing.

Nearly 175 recipes for the use of honey in the Oct. 1st issue, but one good one was left out, and I will give it now.

Ambrosia.—Take equal weights of choice butter and well-ripened, fine-grained, granulated alfalfa or clover honey (other honey of good quality will answer); place in a warm room to soften, then work them together until of even color. Mold to suit.

This makes one of the most delicious spreads that I know of for bread, warm biscuit, or griddle cakes.

The editor, page 697, Sept. 1, inquires whether "those large quadruple winter cases or tenement hives" have made good. I made a large winter case for twelve hives a few years ago, with heavy packing, but do not find any appreciable difference in wintering over those wintered in single double-walled and packed hives except that it makes more work.

Reference is made, page 741, Sept. 15, to the introduction of virgin queens. For many years we have practiced introducing nearly all our queens as virgins into full colonies. We have noticed a great difference in different seasons. Some years, not more than five or eight per cent, while in other years from ten to fifteen per cent fail to give an account of themselves.

Page 730, Sept. 1, T. J. Frost describes his hivestand, which is called "a new hivestand." It is a very good stand, but is not new, as I have had such a stand in use for more than forty years—yes, many of them; but after many years' experience I prefer a front entrance on the bottom-board where one may see at a glance what is going on or what is going in and out of the hive.

Louis Scholl tells us, page 659, that "Bulk comb honey and chunk honey are two different things." Please tell us once more just the difference and we will sit up and take notice. We made a lot of supers last winter to be filled by the bees so we could cut it out and sell in pails; but many of the combs are so filled with bee-bread, or have been occupied with brood, that we are extracting them.

A few weeks ago I was asked to visit a yard of bees some miles away. The proprietor feared he had foul brood. He said he had fifty colonies in the spring in very good condition, but they began to die in May, and he had only twenty left and had failed to secure more than a few cases of surplus honey, although the season had been very favorable. I found no foul brood, but learned that a good deal of spraying had been done in his immediate vicinity.

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

On page 844, Oct. 15, is an article and illustration of my two friends, the bee and the spider. The spider was my friend before I knew the bee. At about the age of seven my father lived on the prairie in Douglas Co., Kansas,

where the life of a small boy was made up principally of the things he found to interest him and fill out his time and employ his energy. I took up the study of the wasp, or, as we called them in those days, "mud-daubers." I did not know I was studying—I simply thought I was playing to fill in the time. But I followed the mud-daubers to the mud by the horse-trough and back to the barn to see where and how they used the mud. I became expert in following them, and solved the mystery of the feeding of the young larvæ.

After the long cells of mud were moulded and sufficiently dried, the wasp began the search for spiders with which to fill the cells, and, strange as it may seem, the spiders pictured on page 844 were the principal kind used by the wasp. Never a very large one nor a very small one, but only those of uniform size, were placed in the cell. When the cell was about half filled, the egg for the future wasp was laid on the body of one of the spiders. The cell is then filled with spiders, and the sealing is done. I formed a boyhood love for the spider, for he made food for my friend the wasp. So while the spider is getting a few of my friends, the bees, they are preyed upon by the wasp, and each in turn helps to work out the plans of a God-given nature, a part of the great plan of the life to fill the world with beauties, wonders, and interest to the fullest extent.

• • •

In the *Country Gentleman* of Sept. 18 I find an editorial headed thus: "A Disease to Beware of." It is so good and so full of simple truths that I give an outline of its contents, *substituting honey for words used therein*. It is a disease that attacks the grower and not the crop. It is spread through a germ, *Sellius ichii*. Now, in plain terms those two words mean itching to sell. The germ is not visible, even under the microscope, but is communicated from person to person in a prosperous farming neighborhood, or caught while talking to honey-buyers or reading the bee-papers.

Shortly after the infection the patient begins to show definite symptoms. First he has a general uneasiness about the size of the crop being harvested in his neighborhood, accompanied by a feeling that crops all over the country are too big. Then follows a depression, with a deep fear that even one hundred million people cannot eat, in the next eight or ten months, all the honey that is being harvested. About the third day after coming down, the patient develops a blind monomania. He is obsessed by the idea that he must sell his crop; must get ahead of his neighbors before they sell and leave him without a market; must get his honey off his hands somehow quickly; must sell! sell! sell! There is never going to be any tomorrow, so far as he can see, nor any next winter, nor any spring. He sees wagonloads, carloads, and trainloads of honey everywhere, and is persuaded that prices are permanently shattered. I will quote the remainder of the article verbatim.

"In this condition he has a pitiable weakness for going into some dark corner with a produce buyer, and, with trembling hands, counting whatever money the latter will give him in actual cash. Or, if he cannot sell to a produce buyer, he will ship on consignment to glutted markets where his crops, joining those of thousands of other growers suffering from the same disease, temporarily demoralizes values. No trustworthy cure for this disease has ever been found. Once attacked, the patient can only allow it to run its course. It ends when his crop has been sold below cost of production, bleeding of his pocketbook, bringing relief of mind. The real remedy is prevention, and the best treatment is mental rather than medical. During the season when there is danger, every grower should build up within himself confidence, assurance that the world will hold together until after harvest, that prices will strengthen when gluts caused by this disease have run their course, and that patience is as necessary in making a profit as any thing done in actually producing the crop!"

If this had been written of the conditions in the California honey market it would not have been—in fact, *could* not have been—any nearer the truth. The California honey market undergoes a violent attack through the producers annually; and if the disease could be cured we should all profit by it.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas.

CARING FOR EMPTY EXTRACTING COMBS IN THE SOUTH.

One of the problems with the beekeepers in the South is that of combating the ravages of the moth larvae, which, if not carefully watched, may mean damaging results to the amount of many dollars in a very short time. They are the most serious enemies to empty combs; and even if they be left unprotected for only a few days their inroads may ruin the best of combs in short order.

Occasionally it becomes necessary to stack the supers containing the freshly extracted combs up near the honey-house before returning them to the outyards. Sometimes they remain here more than a week, and even longer if unfavorable weather and other circumstances delay the work. It is during these periods that the greater danger from their depredation lies. We have experienced some losses ourselves, as well as having seen some of the disastrous results of their work to other beekeepers.

Our remedy now, when we have a large number of these supers stacked up, is to set four stacks of them in a block, close together, about eight to ten feet high. On top of the stack, by means of a step-ladder, we set an empty shallow super into which we place two of the cheap heavy paper picnic plates, and pour into them a quantity of bisulphide of carbon, or "high life." Then we lay a hive-cover on top of each stack of supers, letting them fit as closely as possible, and over the whole block of the four stacks we then place snugly a large heavy duck wagon-sheet or tarpaulin. This reaches nearly to the bottom of the stacks if the supers are piled very high; but we have found the work of the gas just as effective as when the supers are entirely covered. The propolis and wax on the edges of the supers, with the addition of the weight of the supers themselves, tend to seal the hive intersections completely enough so that it is not necessary to paste paper over these as has been often suggested. Our idea of treating these supers is to accomplish the results with as little labor and expense as possible, and we have found the method quite satisfactory. The additional protection of the tarpaulin prevents the air drafts from disturbing the gas fumes within.

SELLING A LARGE CROP OF HONEY.

"Producing a crop of honey is one thing, but selling it is quite another thing," is an old saying that has been often repeated. We have many good beekeepers who are very poor sellers; and unless somebody else sold their honey for them they would have to go out of the producing business.

OUR NEW STATE ENTOMOLOGIST.

The beekeepers of Texas are well aware that I have always been deeply interested in the welfare of our worthy industry. Because of this interest I was prompted to urge the co-operation of the Texas beekeepers in the Sept. 15th issue of GLEANINGS, in the foul-brood-eradication work in this state.

Since this article appeared I have received a very encouraging letter from Director Bonnie Youngblood, of the Texas Experiment Station, assuring us his full support in the work, and the proper expenditure of the appropriation we were so fortunate as to get. Also Prof. F. B. Paddock, our new State Entomologist, has emphasized my recent request for co-operation in a letter which follows:

Hon. Louis H. Scholl:—More than likely you are aware by this time of the appointment of Director Youngblood in regard to Mr. Newell's successor as State Entomologist. In that capacity I am writing you at this time to thank you for the article which appeared in the Sept. 15th issue of GLEANINGS. You have said much of solid truth in that article.

Director Youngblood and myself are very anxious that the beekeepers of the state should get the benefits of the foul-brood law and the appropriations made to support it, both of which have been secured very largely through their efforts and interest. Personally I feel it my duty to give the beekeepers everything possible under the conditions. You are well aware of the fact that we cannot properly conduct the foul-brood-eradication work without the co-operation of the beekeepers of the state. We hope that every beekeeper will follow your suggestions to work hand in hand with the State Entomologist, for, as you say, in this way only can great good come from the work which is now started. We also hope that the beekeepers will correspond with this office in regard to foul-brood-eradication work and the beekeeping problems of the state. Truly we have the chance of a lifetime to do some good work along this line. I certainly trust that the beekeepers will feel satisfied with the results which we hope to obtain in the foul-brood-eradication work in the next two years with a liberal appropriation. I shall ask your hearty co-operation with this office in the work which we are trying to do. By working together we can accomplish much more than by working apart. I certainly trust that your services will be extended to this office in the future as they were in the past.

F. B. PADDOCK,
State Entomologist.

College Station, Tex., Oct. 15.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

GATHERING POLLEN; POINTED
QUEEN-CELLS.

"Will you tell us why bees gather pollen more plentifully in the early part of the day than later?"

I have heard it said that pollen is always fresh and pliable in the early morning hours; and as the day advances, the sun getting higher, the pollen gets too dry to gather easily, and so the work is given up. Another reason which has been given is that the flowers secrete nectar more freely in the latter part of the day, so in their eagerness to secure this nectar they give up or forget all about the pollen till another morning. Whatever of truth there may be in these reasons given, I suspect that in many varieties of flowers like corn, sorrel, narrow-leafed plantain, etc., the pollen is either gathered by the bees or falls off with each rising breeze to do its proper work early in the day, so that the bees have none to gather later.

It may be that, when honey is abundant, carriers of pollen are scarce; but is it not true that when the hard maple and white clover are yielding nectar abundantly pollen is also gathered throughout the whole day? In times when the hard maple blossoms freely I have seen the lengthening cells along the tops of the combs sparkling with nectar, and at the same time the combs next the outside of the brood-nest may be so packed with pollen that the queen has to go clear around to the opposite side of the comb to get a chance to lay her eggs for the expansion of the brood into the next comb. Then with the clover we have pollen and honey gathered at the same time, to the detriment of many a section of honey. Some claim that bees do not gather pollen from clover, as they never see bees with loads of pollen (in clover bloom) before the bees begin to secure nectar, it being a well-established fact that prior to 7:30 A.M. very little nectar is gathered from any of the clovers, on account of the nectar being too thin from the morning dew for paying work. Such a claim is based on careless observation, as clover pollen is not as readily seen as most other kinds, it being a darkish brown. Clover pollen seems to be the only pollen which is covered with honey, and the honey sealed over, thus perfectly preserving it for early spring brooding.

"I notice that some queen-cells during the swarming season are more pointed than others. Which are better—the pointed ones or those round and smooth on the end?"

I cannot see that the wax put on the cell at the end has anything to do with the value of the inmate of the cell. I am inclined to think that the shape of the cell when first finished is due to the peculiarity of the bees building the cells. The real length of the cell is determined by the cocoon spun by the royal occupant. I have never noticed any difference in the shape of the points of queen-cells internally; but often, after cells are capped, the bees decorate the free end with a point of wax so as to make it look much longer and sharper. These cells will all be nicely rounded off in a few days, as this wax is generally carefully removed before cells are ready to hatch.

"I see that you have 'started something' by telling how a queen pipes. But I fear some of the discussion is not orthodox."

Sorry our correspondent does not specify what he considers unorthodox. Dr. Miller, p. 835, quotes Baron Berlepsch, who would have us understand all queens quahk at their maturity. This is certainly a mistake, as all know who have seen a mature queen emerging from her cell. Such queens are as white, weak, and fuzzy, as are the mature workers when they come out of their cells. It is only as either of these partake of food that they begin to assert themselves. I am led to believe that no queen ever piped or quahked in less time than 18 hours after she had taken food; and the first of any batch of queens emerging comes out white and fuzzy, as I have often proven by close observation during more than forty years.

The editor, p. 790, and p. 835, would make a poor showing, only that he tells us that he does not know very much about this whole proposition. He tells us about quahking queens having "less air," and refers to the waxen cells as being nearly air-tight, while all close observers know that no queen ever quahks until she has made an incision through the capping of her cell of sufficient extent to thrust her tongue through and partake of food given her by bees outside. Here is where Arthur C. Miller fell down in his theory that queens are never fed only as they lay hold of the workers and demand food by force. As Dr. Miller says, the piping queen gives the challenge, and then all the queens in their cells which have been fed by the workers for eighteen hours or more go to quahking. A quahking queen is held in the cell by a few bees holding the cell-cover on immediately on her maturity, and the cover is never so held except when another queen has her liberty in the hive.

GENERAL CORRESPONDENCE

EIGHT OR TEN FRAME HIVES

BY E. F. ATWATER

There have been some differences of opinion as to the proper inside widths of our "standard" hives. As I have done a large part of the frame manipulation of an average of 1000 colonies, from one to six stories high, for a number of years, perhaps my opinion may have some weight.

C. P. Dadant says, "Properly made hives should have the same space, per frame, whether they are twelve-frame hives or six-frame." Dr. Miller says, "Aye, they should have; but they don't have—at least eight-frame and ten-frame hives don't."

The inside width of the standard eight-frame hive is $12\frac{1}{8}$ inches, or $1\frac{1}{8}$ inches more than is occupied by the eight self-spacing frames (which occupy 11 inches). The standard ten-frame hive is $14\frac{1}{4}$ inches wide inside, though one manufacturer has adopted a new width of $14\frac{1}{2}$ inches.

Now, as the eight-frame hive is admittedly going out, there is no need to correct its shortcomings. As the eight-frame hive has room for eight frames, and a thin division-board (not over $\frac{3}{8}$ inch thick), it is seriously faulty. That flimsy, worthless follower is one of the worst nuisances ever put in a hive.

If propolis is at all plentiful the division-board is often broken when being removed, and sooner or later is left out entirely, and the self-spacing feature of the frames virtually destroyed. If tightly crowded together, comb will be built at the sides, as there is too much space there.

The great mistake in the first place was in not making a nine-frame hive. Then the advocate of an eight-frame brood-nest could use eight frames and a heavy dummy, to take the place of the ninth frame. Upon the removal of the dummy there would be ample room to manipulate the frames. The heavy dummy would last for years—nothing flimsy about it.

For several years I had 200 hives with sides only $\frac{5}{8}$ inch thick, which gave a nine-frame space inside, outside width 14 inches. These tier to good advantage with all eight-frame equipment, and contain eight frames and a heavy dummy. They were far more satisfactory for brood-nests than the usual eight-frame inside width with the toy division-board, and had the additional advantage of giving a little more room for honey,

when used as extracting-supers. Sometimes we used nine frames in the brood-nest.

If such nine-frame hive had been adopted years ago, today it might easily be an almost universal standard, as the ten-frame is not enough larger to justify the existence of two sizes. The nine-frame hive is extensively used in Utah and California.

But the tide has set in so strongly to the ten-frame hive, and tens of thousands of them are in use, of a width of $14\frac{1}{4}$ inside, 16 outside. Anything wider makes endless confusion for those who have telescope lids. Therefore I am confident that it is a serious mistake to make the ten-frame hive $16\frac{1}{4}$ width outside.

No one with much experience with the Hoffman frame will contend that the $16\frac{1}{4}$ width gives room for the use of even the hopelessly frail division-board beside the frames. True, at times the removal of the first Hoffman frame is quite difficult, with the standard width, outside, of 16 inches or $14\frac{1}{4}$ inside.

If a little more space is desirable, better by far to continue the old sixteen-inch standard width, outside, and make the sides of 13-16, or even $\frac{3}{4}$ inch lumber, to gain $\frac{1}{8}$ or $\frac{1}{4}$ inch more inside width. I have thousands of hive sides $\frac{3}{4}$ to 13-16 inch thick, and there is no appreciable difference in strength or durability, compared with the full $\frac{7}{8}$ thickness.

This change should meet the approval of all supply dealers, as even now several firms have had to give up the use of full $\frac{7}{8}$ -inch lumber, as most mills do not saw lumber that can be dressed on two sides, and be over 13-16 inch thick.

If the advocates of the eight-frame hives could be compelled for five years to use the ten-frame size, with nine frames and a heavy dummy, there would not thereafter be much call for eight-frame hives. The ten-frame hive with nine frames and a heavy dummy, or division-board, is a splendid comb-honey hive, and, if you have a good ten-frame strain of bees you can use the full ten-frame brood-nest.

For many years I was an advocate of the eight-frame hive, but using many of the tens all along. A few years ago experience proved that anything that could be done with the small hive could be as well or

better accomplished with the ten-frame hive. We now have far more of the ten-frame size—several yards contain no other.

In conclusion I want to urge that manufacturers do not change the old standard

outside width of 16 inches for the ten-frame hive; but if $\frac{1}{8}$ to $\frac{1}{4}$ inch more inside width is needed, make the hive sides of 13-16 or $\frac{3}{4}$ inch lumber.

Meridian, Idaho.

A WINTER-CASE HOLDING A WHOLE ROW OF HIVES

BY R. C. GIFFORD

Recently a number of the "big fellows" of the beekeeping world have been advocating the use of square winter-cases which protect four colonies. In these cases two of the colonies have to face either east or south, and the other two north or west. As one of the very "little fellows" of the beekeeping world I can't help feeling that this plan would be anything but successful in the hands of the average folks like myself.

In this locality there is a lot of damp cold wind during the winter. We use the expression "It chills you to the backbone" to describe it. I'm afraid if my bees had to sit

mended by several. It has always given perfect satisfaction. It is also much cheaper because any kind of boards can be used for the top and sides. Of course the two ends for the case are built for that purpose, and nailed securely, because the long boards are all fastened to them. The ends I use are 28 inches wide by 23 high, and have a three-inch slope toward the front.

The tar-paper cover is held in place along the north side and corners of the south side by nails driven through long narrow boards. Weights hold it securely on the top. With this method, if the paper is put on and

taken off during the middle of the day while it is soft from the sun's rays, it can be kept in good condition for several years. Then, too, the paper stays where it belongs. The first year, I nailed the paper on securely with the nails which come with it. In the middle of the winter we had a severe blizzard, and the wind managed to get under that stuff and tear it all to pieces. Of course it had to be replaced immediately, so the

entire family had to wade out among the snowdrifts and literally sit on the paper while I fastened it down with weights and nails driven through lath.

WINTER STORES.

On the first frosty morning after the honey-flow is over, the colonies are weighed. Two people do the work because it is too heavy and awkward for one. The colonies are weighed, one at a time, on platform scales which are trundled wherever desired, on a wheelbarrow. Each colony has to weigh 35 pounds after the weight of the hive-body, bottom-board, and cover are deducted. If it doesn't, sugar syrup is fed.

When this work is done on a cool morning the bees are not disturbed so much, and

The long case is cheap, and has always given perfect satisfaction.

with their open entrances toward the north or west all winter this wind would chill them to their backbones, and I should have nothing but some frames and hives when spring came.

Another thing to be considered is the peace and comfort of the beekeeper. I think the majority of beekeepers have bees because they really like them. Well, imagine going to your warm comfortable bed some night with half of your hives facing the north and west, when the wind is moaning around the house and even driving the snow through the tiny cracks around your bedroom window. You would not enjoy the night's rest, would you?

I have always used the long case recom-

they do not disturb us so much. To help along still more, so they won't disturb us at all, we lay a damp cloth across the entrance just before we set the colony on the scales, and leave it there several minutes after the colony has been returned to the

stand. If four damp cloths are used, the hives can be handled as fast as two people can work, and the bees won't be likely to raise a rumpus.

THE VALUE OF ITALIAN BEES IN FIGHTING EUROPEAN FOUL BROOD

BY H. HARLEY SELWYN

It seems to me our veteran Canadian beekeeper, Mr. Holtermann, needs some cheering up on the matter of European foul brood (see GLEANINGS, page 707, Sept. 1). It does sound odd to me to hear of one who has been so long in the business meeting only now with this disease. My bees and European foul brood have grown up together, and I feel I know its vagaries so well it causes me little more worry than an absconding swarm in August. In fact, I

have such peace of mind in regard to it now that I hope to lighten our good friend of this incubus which apparently has come to burden his mind.

To sum the whole matter up in a nutshell, I believe in and practice the three words, "Keep Italian bees." They will look after European foul brood, and if Mr. Holtermann or any one else does the same his troubles will shortly be at an end.

While on the topic of European foul brood there are some observations I should like to make. These are based on experience, and may be useful to those having yet to encounter the disease. In the first place, let me say that I would have Italianized before the disease was brought to the yard had I known then what I know now. The penalty I paid was to lose a crop of honey, render down over 1600 combs, and work day and night to save any bees at all.

Notwithstanding the fact that Italians can rise up in the midst of European foul brood and overcome it, I believe that they must suffer first (some worse than others) before becoming immune to other ravages. This question of immunity should, in my opinion, receive more consideration. Disease comes to a man's yard. He Italianizes,

Sections placed in a super without starters. Note the different construction of comb in each section, and imagine the trouble in removing them from the super. Photographed by Charles Y. Hake.

Showing more in detail how the bees worked without starters. Photographed by Hake.

and works hard for several years treating disease by shaking, requeening, and feeding. After a time he finds the colonies are all quite healthy. Such conditions hold good as long as he keeps his pure-bred Italian queens heading each colony.

It is to be understood that he has done his own breeding and selecting from those hives surmounting disease most rapidly. Then comes the day when a very dark cross dominates a colony. At the first honey dearth of consequence this hive shows diseased larvæ badly. Where did the disease come from? That is what is puzzling many beekeepers today. At any rate the point I wish to make is this: Italians must become immune; and as long as that strain continues in a yard, everything goes well. To carry the point further, I would also state disease might be *prevented* in many another man's yard by the introduction and use of such immune strains of bees. In fact, I have seen it done.

Furthermore, there is the matter of the spread of European foul brood through shipment of colonies of bees to outside points. I should like to inquire whether the government is going to be able to control this spread of disease when Italian colonies can harbor the disease from season to season without its appearance until the chance comes for a reversion to the black strain of bee. It does not seem to me that any amount of quarantining will bring it to

light under such conditions. In my own yard, for instance, I feel I am safe in offering to have the best foul-brood expert in Canada come and examine every hive for

A wasp-nest beside a honeycomb in the section. Photographed by Hake.

disease without a chance of his finding anything wrong. Yet I know the disease is present.

Last spring, during my absence for a few days, Mr. P. H. Selwyn put out some dozen supers which had been stored away since disease first hit this district. They contained dried-up larvæ and honey—the very best of materials to distribute disease wholesale. These supers were put on strong colonies to receive the surplus, then beginning to come in. At that time my hives were, to all appearances, clean and strong. Had this taken place in a yard of blacks or Italians that never had encountered the disease, I have a fairly good idea what would have followed. What do you suppose did

happen? The immunity theory worked as I have outlined, and nothing ever came of the unintentional experiment.

There is work here for investigation by the government officials in connection with apiculture. It is no joke for the man dependent on his bread and butter from the bees to experiment with European foul brood.

Mr. Sladen, Experimental Farm, Ottawa, did, I believe, try something of this sort with the apiary in his charge, but I have not learned the outcome of it. I know he wished to secure from me a rattling good case of disease (hive and all) to try to re-infect his bees.

Kirk's Ferry, Quebec.

EUROPEAN FOUL BROOD NOT A CALAMITY

BY EARL SEAMANS

I consider European foul brood a blessing. We have had it in Wyoming County for the past eight or ten years, and every year I have had some of it in my own yard, and in no year have I failed to secure a crop of honey. This season I found five colonies affected with it in a yard of fifty-eight colonies.

European foul brood has compelled me to purchase several Italian queens each year to replace diseased queens. This has increased the value of my stock, which has proved to be one blessing. Then the disease has put a number of slip-shod beekeepers out of business. That is another blessing. I have never lost or destroyed a single comb on account of this disease. When it first appeared around here I sent for the "Alexander Book." That book was worth its weight in gold to me.

A hive containing European foul brood should be labeled "Diseased queen," and treated accordingly. The queen, and not the bees, is the source of trouble. I have placed as many as three upper stories filled with foul brood on top of a healthy colony with a sheet of queen-excluding zinc under them to prevent the queen going up, and I have never had the disease carried from the top down into the bottom.

This summer I caged a queen from a diseased colony about a week, and then put her and the bees on clean combs. In one month that colony was as bad as ever, which proves that the queen carries the disease. Shaking the bees into a hive filled with starters or full sheets of foundation will do no good unless the queen that was in the diseased colony is killed.

Ten years ago my brother had several

hundred colonies in this section when he found European foul brood. He removed all the brood and honey and destroyed it; then he charred the hive and put the bees and queen back on full sheets of foundation. Did it do any good? No. The queen was diseased, and carried the disease into the clean hive. He now has less than fifty colonies.

Kill the diseased queen; lift out all the frames of bees, brood, and honey; put a frame of clean brood and some clean combs in the hive, and then shake the bees in front of the hive, giving them a good Italian queen. If during a honey-flow the queen can be run in with the bees, at other times she should be introduced by the cage method. The frames containing the foul brood can be placed on top over a sheet of perforated zinc, or may be put over a sheet of perforated zinc on another colony without any danger of the disease being carried below.

This summer I tried to run in a valuable queen with the bees at the entrance. They killed the attendant bees and balled the queen. I threw the ball of bees and queen into a pail of lukewarm water. When they liberated her I put her back into the cage and put a number of newly hatched bees from the same colony into the cage with her. Then I placed the cage on top of the frames and let the bees "eat her out." They accepted her all right.

I have secured a good crop of clover and buckwheat honey. On the first day of September one of my hives sent out a very large prime swarm, which is the latest date I ever had one.

Factoryville, Pa.

A NEW WRINKLE IN HIVE-COVERS

BY E. M. CROW

The accompanying illustration shows a device which I am using with a great deal of satisfaction in my beeyard. For want of a better name it might be called a combination hive-cover and nucleus-box.

The box is made of two pieces of $5\frac{1}{2}$ -inch bevel siding 20 inches long ($\frac{1}{2}$ -inch stuff of even thickness would be better), and two end blocks $\frac{7}{8} \times 5 \times 5\frac{5}{8}$ inches deep. It will hold three shallow extracting-frames. Projecting from the lower edge of the box on either side is a double cover made of two pieces of bevel siding 20 inches long, held apart by three $\frac{3}{8}$ -inch cleats. This makes a

cover just right for a ten-frame hive. A $\frac{7}{8}$ -inch board, 6 inches wide and 20 long, makes a good cover for the nucleus-box part.

The uses to which this appliance may be put are varied. In the first place it is a No. 1 hive-cover for hot or cold weather; and if kept painted it will last as long as any other cover. Should you wish to requeen a colony, put a frame of brood and bees with a ripe cell in the box over the doomed queen, with a wire cloth between, and the flight-hole open to the rear. When the new queen has mated, and is laying, quietly remove the old queen and the wire cloth, and there you are with no time lost.

Do you wish to feed a colony? You have but to place four pepper-box feeders in the box directly on the brood-frames, and the work is done. Queen-rearing can be carried on in almost any kind of weather by the use of these boxes over a strong colony with wire cloth between.

The use of the bevel siding for the roof part gives a good pitch to the upper surface while the under side is held level by end cleats.

De Soto, Mo.

THE ISLE OF WIGHT DISEASE IN WASHINGTON

BY T. DWIGHT WHITMAN

There was practically no crop of honey locally, and considerable loss of bees from what I consider a form of the disease known as Isle of Wight disease. Either from this disease or the fumes from our local smelter, which was treating more copper than usual, and which killed the peas and beans, and showed on the foliage of my trees, I lost eighteen out of twenty stands. The two that survived were helped out with brood from Puyallup. I used the uncapped honey from the hives that died to see if it had any injurious effect on the bees. Apparently it did not. Only the adult bees were affected, the loss of brood being from chilling. The colonies lost strength so rapidly that they could not take care of the brood they had. The queen laid to the last, but with fewer and fewer eggs.

Of the two hives that I have left, one still shows symptoms of the disease. The other seems to have got entirely rid of it. Both were treated exactly alike, and both fed

with the uncapped honey from the stands which died.

I am watching them closely to see what the outcome will be. The bees were working and carrying in pollen in both hives today. Goldenrod and catnip are in bloom.

The disease, whatever it was, seemed to affect old and young adult bees except the drones, which were not affected. In the early morning the ground in front of the hives would be covered with bees seemingly unable to fly. If the sun came out and warmed them up, a large proportion would fly away, but few would return to the hive. Their bodies would be distended. When squeezed, some appeared to be empty, others full of a white watery matter, others as when they have dysentery. Dead bees had protruding tongues. There was no trembling, nor motions of the wings. They gathered in bunches on a rock or piece of wood in front of the hive, and seemed without ambition to do anything.

Tacoma, Wash.

TREATING AMERICAN FOUL BROOD

"A Movie Scenario"

BY BENJAMIN WALLACE
DOUGLASS

Each frame in the hive should be carefully inspected for foul brood.

If the frame is held upside down it is very easy to detect the presence of the American foul-brood "scales" on the side of the cells.

When foul brood has been found, the beekeeper should at once make preparations to treat the disease.

A new hive is provided with starters of foundation. A wash-boiler of water is also near at hand.

The old hive is set at one side and the new hive is placed on the old hive-stand.

The bees are now ready to be brushed into the new hive. They should not be shaken, as to do so will also shake some of the infected honey in with them.

The bees are now brushed into the new hive. The best brush is one made of a wisp of grass or weeds. After use it can be burned.

As soon as the bees have been removed from the diseased comb, the entire comb should be placed in a wash-boiler containing water. This prevents the bees from gathering on the old comb again, and prevents robbing.

Trevlæ, Ind.

RANDOM NOTES ON BEE BOTANY

The Largest Flower Cluster in the World

BY JOHN H. LOVELL

The Talipot palm grows for thirty or more years, until it reaches the height of sixty feet without blooming once. Its home is in the damp forests of Ceylon. Then from its apex there springs an enormous cluster of flowers 40 feet long by 35 feet wide, composed of innumerable blossoms. The flowering period lasts for about four weeks. As soon as the fruit matures the whole tree dies like the century plant. It blooms only once.

FOLIAGE AS A SOURCE OF NECTAR.

The leaves of the partridge pea and of cotton are the source of a large quantity of nectar. When the atmospheric conditions are just right a bee can often obtain a

load from one or two glands. Phillips states that majugua, a common plant in Porto Rico, has extra-floral nectaries on the leaves, and that he has seen ants working on them. The leaves of many of our native herbs and trees also possess nectaries, as the vetches, castor-oil bean, the brambles, cherries and plum, poplars and maples; but, unfortunately, they secrete very little nectar. But could we not obtain by selection varieties that would yield nectar abundantly? If this could be done the possibilities can hardly be imagined. Various ferns, which are, of course, without flowers, also have nectaries.

THE USEFUL BLUEGUM.

In the delta of the Orinoco River there grows the mauritia palm-tree, on which a whole tribe of Indians depends for existence. They dwell among its branches, and it affords them fuel, food, wine, cloth, twine, etc. It is well called the "tree of life."

The bluegum (*Eucalyptus globulus*), now largely planted in California, has almost as many uses. The very hard close-grained wood is valuable for fuel, furniture, telegraph-poles, railway-ties, vehicles, fence-posts, wood paving, etc. The flowers are a source of much honey; the leaves and twigs yield a medicinal oil, and the bark may prove of importance in tanning and paper-making. The trees form excellent wind-breaks, destroy malaria, drain damp soil, and are a handsome landscape tree. It is the fastest-growing tree in the world, and one of the tallest. Photographs of the flow-

ers and fruit of many species of eucalyptus are given in Bulletin 225, Agr. Exp. Station, Berkeley, Cal. The picture of the

flower and nut-like fruits of the bluegum is natural size.

Waldoboro, Maine.

BEEES IN THE HONEY- HOUSE

BY FRANK L. POLLOCK

Bee-escapes on the honey-house windows at extracting time have proved a two-edged sword with me. The escaping bees return and hover about the screen windows as long as they live, and sometimes succeed in finding a way in through some tiny unsuspected hole. I was forced to adopt the Townsend method of closing the escapes till after extracting, and then carrying out a big cluster of bees all at once. But it is annoying to have the honey-house full of bees while extracting is going on, crawling over the floor, getting into the honey, and causing innumerable stings, especially to the uncapper.

I have hit upon the following device, which turned out very useful. In each upper corner of the screen window is a cone escape, with a pretty large opening. This does not lead into the open air at all, but into a box about a foot square, hung on the outside of the honey-house by two hooks. This box has two sides of wire cloth, and one of the wooden sides is on hinges, and can be opened out like a door.

The large cone escapes keep the window well clear of bees all the time, and they go out into this box and no further. A few

may possibly come back. At the end of the day the box may be unhooked, carried into the yard, and the bees dumped out, without any danger of their locating the screen window.

I was forced to this expedient by my bees developing a peculiarly ingenious form of robbing this summer. The bees that were carried into the honey-house on the combs presently seemed to content themselves pretty well, and I discovered that they were doing a lond-office business by carrying honey to the screen window and passing it through to the bees on the outside. Having unloaded in this way they went back to the uncapping-box for more.

I sat and watched them at this for some time, and I observed that almost every bee that took wing loaded from the cappings ejected a fine spray of fluid before reaching the window. This has often been observed when bees were taking thin nectar, and is supposed to be the superfluous water; but this was very thick well-ripened honey. Where did that surplus water come from?

Incidentally I would venture to say that I think the plain wire cone is the best form of bee-escape yet devised. An escape-board

Flower and fruit of the bluegum (*Eucalyptus globulus*). Natural size. (From Bulletin Agr. Exp. Sta., Cal.)

with an opening two or three inches in diameter, and a single flat cone on the other side, will clear a super considerably quicker than any other. It is unnecessary to have several cones within each other, as in the Lareese escape. A single triangle with one of the corners open wide enough for a drone to pass is all that is needed. I have watched bees trying to pass out the Porter

escape. They do not like to force the springs aside, and will hesitate and back away, causing a great deal of delay, while they go instantly through the open cone. It is true a few bees may pass back through the cone; but a dozen odd bees in the super are of no consequence, and I have never found more than that.

Stouffville, Ont., Can.

NOTES FROM THE APIARY; A NEW METHOD FOR SECTION HONEY

BY JOSEPH GRAY

Any method of comb-honey production that will enable the extracting man to find new outlets for his honey at small initial expense is worthy of trial.

My supers were filled with six extracting-combs and one section frame, the latter occupying the center of the super. The section-frame was made of plain $1\frac{1}{2}$ -inch material, and held eight plain sections $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$. The sections, when fitted with full sheets of foundation and separators, were made from castaway fruit-boxes.

The only parts cut by machine were the 3-16-inch strips for the edge of the big separator. The two separators were held

in place at the bottom with straps of tin so that, when set in, the section-frame was properly spaced. The advantage of this method is that the frame only is spaced, not each individual section, and no new appliance is needed in an extracting apiary except the frame and separators. This leaves the apiarist free to take both comb and extracted honey from his strongest colonies.

CONDITIONING HONEY.

As we use a tank of 6000 lbs. capacity, I wanted a reliable way to leave my honey in as good condition as possible when filling cans. I found it by having a tank within a

tank, and a full-length wire-cloth screen within the inner tank. The honey is siphoned from the inner tank to the outer

crack of the cover and super of freshly closed hives. Dry soil is a good temporary entrance-closer.

tank, as shown is the illustration; and as the honey is also siphoned into the screen I get a clean well-ripened article.

HIVE PLIERS.

I note the editor is recommending the use of hive-pliers or tongs for foul-brood inspectors. Why not for the beekeepers? They are time-savers. Mine are in daily use. They will grasp a 10-lb. comb easily with one hand, leaving the other hand free to brush off the bees. Besides fewer stings and quicker work, they save backache.

STAGGERED HIVES.

I had of necessity to crowd my hives under one ramada. In all pictures shown of bees under a shed or ramada they are in one continuous line. To overcome this sameness I staggered the hives; between the first two posts I advanced the four center ones, leaving the two at each end in the original line. Of the next eight I put the second, third, sixth, and seventh forward, leaving the others in their original places. In actual work I was agreeably surprised to find more elbow room.

COAL OIL FOR ROBBERS.

When robbing is prevalent the clearing-away of all fresh propolized quilts, extra supers, etc., is important. Never use propolized sack quilts for smoker fuel. With a paint-brush and coal oil, go round each

HONEY-LOADER.

Having a considerable amount of honey to load, the task was lightened by a mechanical loader, an upright carrying a cross-beam at one end, with rope and grab-hook, and at the other end a trail-rope. This readily lifted the 140-lb. cases from the ground to the wagon.

PRY FOR CASES.

A pry is made with a wooden shaft, the bottom fitted with a blade and a prong.

The blade is caught against the end of the case; the prong bites the ear floor; a pull on the shaft, and the case is in its place.

LEAVES FROM THE RECORD-BOOK.

Dr. Miller keeps a record-book. My hive-cover is a leaf of my record-book; every leaf is thus open to inspection as I walk down the apiary. Take queen-raising :

WANTED BEES	QUEEN	SPARE BEES
STORES	VIRGIN	STORES
CELL	CELL	CELL

There are nine places that are sufficient. In a moment you can tell where to find bees, stores, or cells. In case of cells, four lumps of earth are grouped for four cells.

Suppose you want a choice queen, or more than one. You do not open a hive needlessly, but go only to those with queens. Examine each. If extra good, place on it

three clods of earth; if good, two clods; if medium, one clod. Now you have your queen graded according to your judgment. Heber, Cal.

[This is the second of a series of two articles by Mr. Gray on handy appliances in the apiary.—Ed.]

OKLAHOMA HAS A BEE LAW

BY N. FRED GARDNER

J. E. Lemon, of Grant County, Oklahoma, representative in the Oklahoma legislature, is the man to whom Oklahoma beekeepers should extend grateful thanks for the enactment of the bill introduced in their behalf.

This law became effective June 3, 1915; and while, no doubt, many Oklahoma beekeepers are not aware of its existence, it stands ready to be applied when the need is felt. This bill carries with it the provision that I believe has not been duplicated by any law in any other state, and it remains for time to determine whether or not they are wise. This is to the effect that shipments of bees, queens, honey, etc., must bear certificates of inspection similar to those required by the nursery-inspection laws; or in case of no inspector where shipment originated, that a certificate subscribed and sworn to before a notary public.

The beekeepers of Oklahoma did not give Mr. Lemon the support that he should have had in passing this measure, but he succeeded in putting it through because of the high regard and confidence in which he was held by his colleagues of the legislature.

Geary, Okla.

J. E. Lemon pushed an up-to-date bee-law through the Oklahoma legislature.

CALIFORNIA FIELD MEET IN OCTOBER

BY FLORA M'INTYRE

The Ventura County Beekeepers' Club held a picnic meeting, Oct. 2, at the apiary of Mr. Wm. H. Allen, near Saticoy. Seven or eight automobiles brought the crowd and stood about, lending an air of prosperity to the scene. A long table made of stacked empty hives was provided on which our basket lunches were spread, and also the coffee, doughnuts, sandwiches, and mince pies offered by our host. I regret not having a picture of the scene with the eucalyptus-trees all about, and the apiary a few hundred feet below the festal board.

Our state senator, Dr. Mott, gave a talk on proposed legislation of particular inter-

est to beekeepers. He mentioned especially the plan to establish a state agricultural bureau analogous to the national institution for the same purpose, and having a department devoted to apiculture, this one bureau to replace the various state commissions which now cover somewhat the same ground. He urged the need for educating the legislators and the public in general concerning the contribution of the bees, both directly and indirectly, to the wealth of the state. He remarked that there was some foul brood in the legislature as well as in the apiaries ("fool brood I would call it," afterward remarked a small boy who was in

attendance, with both his ears wide open).

A paper on the benefits of bees to the fruit-grower, by Prof. A. J. Cook, State Horticultural Commissioner, was read before the meeting. Among other things he mentioned the complaint sometimes made against the bees that they carry pear blight. He said that, while it was doubtless possible for bees to spread this disease in the same manner as do other insects, they are only one of a number of agents that do this, and their removal would not greatly affect the amount of pear blight; that the beneficial work of the bees as pollenizing agents vastly outweighs any harm they might do by spreading pear blight.

Among others, President Wood called

upon Mr. J. D. Bixby, editor of the *West-corn Honeybee*, and a visitor from Covina. Mr. Bixby gave some conclusions from his experience with European foul brood, emphasizing the fact that he considered it necessary to melt up all combs containing or having contained diseased brood, but not other combs, in the diseased colony—as, for instance, super combs above a queen-excluder.

The meeting was one of the most interesting the club has had for some time, and would doubtless have been of benefit to some who were kept away perhaps by the rather cool cloudiness of the day.

Ventura, Cal.

A PROCEDURE FOR LATE FALL QUEEN-MATING

BY JOHN L. BYARD

Read before the Hampshire, Hampden, Franklin Beekeepers' Association, March 19, Northampton, Mass.

Having for some time presumed that I could procure select matings of queens during late August or early September, I devised what, perhaps, is a process with some unique features. These do not pertain particularly to the mating of the queens, but more especially to the nucleus in which mating occurs. I first selected a drone colony. This was done late in August. Queen-cells containing maturing queens were then procured, caged, and made ready for introduction. When introduced the queens were left for several weeks without attention, at the end of which time a large percentage of the queens were found mated.

The nuclei were prepared as follows:

Nucleus hives were the combination boxes in which either four full Langstroth frames could be hung or a larger number of Benton frames (one-third the size of the Langstroth frame, and hung in the opposite direction). I first supplied a candy-feeder in the form of a division-board. A frame containing a piece of new bright comb the size of a quarter or fifty-cent piece was then added. Sometimes, instead of this small piece of comb, I supplied a frame with a narrow starter. Two

or three frames with starters were also supplied on either side of the center comb.

When the nucleus was prepared, I shook a quart of queenless bees into the hive, closed the entrance, and set the nucleus in the shade. The next day, at about four in the afternoon, the virgin queens having hatched, I ran one into each nucleus, closing the entrance. On the following day I removed the entrance-block, liberating the

Scene of the Massachusetts convention at Stoughton this summer. The little hives could be opened without smoke or veil.

bees. These nuclei were then without attention for two weeks, after which time I found nine queens laying. It should be stated, however, that in introducing the virgins one was killed and one escaped in handling.

As a result, from nine virgins thus handled eight were purely mated and one was

doubtful. She is considered doubtful in her purity of mating only as imperfectly marked bees were seen in her nucleus. This may be due, however, to straying bees from nearby hybrid colonies.

The apparent success of these matings, even though they were not tested beyond the limitations of the fall of 1914, suggests at least that there are possibilities in this method of handling queens for pure mating. It is a rather extreme process, yet shows with decisiveness the value of fall manipulation.

With respect to the candy above mentioned, it should be stated that this is a variation of the Fuller candy, which calls for 12

pounds of granulated sugar. The candy which I used was made with nine pounds of granulated sugar and three pounds of coffee A sugar. I consider the coffee A sugar of value because it tends to keep the candy soft, which perhaps enables the bees to work it for a longer time.

In summarizing, I wish to emphasize that I am not aware of previous attempts of using candy and foundation alone, or a small piece of dry comb and candy. This process, together with the procedure late in the season, which is explained, tends to insure purity of mating, are the three items which I wish to report.

THE EDITOR'S VISIT TO GRIFFITH PARK NEAR PASADENA, WITH ITS CELEBRATED BEE ROCK AND BEE TREES

BY E. R. ROOT

In the last issue I referred to the fact that Mr. F. R. Buchanan, a former traveling salesman, and now of Glendale, Cal., took a party of us, including Mrs. Buchanan, Mr. and Mrs. Frank McNay, and myself, to Griffith Park, near Pasadena, Cal. This park, as has been stated, has a peculiar charm and interest for beekeepers in that it contains a natural curiosity in the way of an enormous bee-rock that has many colonies of bees. This rock was shown on the cover of our issue for November 1.

Besides this rock there are a number of bee-trees; but two or them had their bee-cavities so near the ground that the bees could be seen going in and out, without let or hindrance. Mr. Buchanan crawled up on a limb of one of the trees where there was one large knot-hole; and while stationed at that point I went up on a rise of ground, and caught him in the act of looking down into the bee-hole—see Fig. 1.

The other bee-tree is shown in Fig. 2. The entranceway is also within easy reach, and so near the ground, in fact, that Mr. Buchanan on the left and Mr. McNay on the right are looking down into the cavity, into which at the time the bees were going back and forth. Both men, as will be observed, are slightly baldheaded; and had the bees been disposed to be at all obstreperous they might have made the two who were "sticking their noses into other people's business" not a little trouble; but even though Mr. McNay put his hand into the opening there was no hostile demonstration.

Mr. Buchanan

FIG. 1. Mr. F. R. Buchanan inspecting the entrance of a bee tree in Griffith Park, California.

FIG. 2.—Sticking their noses in other people's business.

drove us all over this park, then up around and on top of the mountains, for there are beautiful automobile drives in all directions in the mountains near Pasadena. I shall not soon forget this ride up into the very clouds; for from these heights one can look down on the cities and towns of this beautiful southern California—a country that abounds in bees and beekeepers, for bees seem to be everywhere.

A HOME-MADE BUZZ-SAW.

In our last issue I stated that Mr. McNay had retired, having only one colony of bees with which he amused himself. He also finds pleasure and recreation in other ways. In his back yard he has a workshop with carpenter tools and a home-made buzz-saw made out of an old worn-out bicycle. In Fig. 3 we see the outfit just as Mr. McNay used it in his workshop. The bi-

cycle frame is mounted slightly in front of and beneath the saw-table proper. The rear wheel, minus its pneumatic tire, is mounted directly beneath the saw-table in such a way that the two sprockets are in exact alignment. The bicycle chain, slightly

FIG. 3.—Frank McNay's home-made buzz-saw table, using an old bicycle for the motive power.

lengthened out with more links, is made to drive the rear wheel now placed forward under the saw-table from the crank sprocket. Directly over this rear wheel is a little pulley that drives the mandrel of the buzz-saw. A suitable belt runs from the hollowed-out rim of the bicycle wheel to the mandrel above.

The operator places himself on the saddle of the bicycle, his feet on the cranks, when, presto! he can drive his buzz-saw at a high rate of speed.

Mr. McNay says that with this home-made outfit he has made different articles of furniture that decorate his home, and also parts of hives, for with this outfit he can make almost anything he desires, and at the

same time it affords him much pleasure.

It should be observed in this connection that Mr. Frank McNay tested out the first Cowan reversible extractor we ever made. Knowing him to be an extensive beekeeper, and capable of judging of the merits of a new device of this sort, we sent him our first model; and when he pronounced it good we went ahead and put the machine on the market—practically the same machine bearing today the name of the “Cowan two-frame rapid extractor.”

Mr. F. R. Buchanan, likewise retired, takes his playthings with his big powerful automobile and with the bees. He knows every beekeeper in the vicinity, for he has motored all over the country.

PUT A GUARD OVER YOUR SAW

BY MAJOR SHALLARD

I have an iron guard over mine now; but if I had only put it over earlier I would now have two hands (see p. 863, Oct. 15).

Possibly some particulars of my mishap may be of interest. I was ripping top-bars when my foot slipped on the sawdust, and my left hand came in contact with the saw, cutting the palm across and the thumb off at the bottom joint. As soon as I saw what the trouble was I grabbed the arteries, stopped the engine with my foot, and started off down the road for help. My object was to get away before my wife saw the hand, as she has heart trouble. After going about a mile I met a man in a sulky, and got a ligature around one wrist and a towel over the hand, which then did not look so bad. I sent the sulky for Mrs. Shallard; and when she came we went into Woodburn (two miles), and I tried to ring up the Coraki doctor, eleven miles away. Failing in this we got a car and started for the Coraki hospital. On the way “the necessary” got running away from me so fast that I asked my wife if she could tie her handkerchief around the wrist. She managed it all right, although she got her hands

covered with blood, and she usually faints if she sees a cut finger. She held up very bravely all through, and I say thank God for a good wife.

We reached the hospital at 1:10, or one and a half hours after the mishap, and I had to wait until 3:20 for another doctor from Lisinore, 20 miles away. They operated then, and I woke up at 1 o'clock next morning minus everything but the palm, but feeling good and happy. They were very kind in the hospital; and as my wife stayed and looked after me we had quite a jolly time. In fourteen days I left the hospital with nearly all the outside wounds healed, which shows I had very little poison in my system. Had I been a whisky-drinker I should probably have come out feet first.

It is five weeks today since the accident, and the hand is getting on nicely, although it will not be ready for work for some time to come. Meanwhile my son Phil is hustling the business wagon along, and I am occupying a box seat, looking out for stumps.

S. Woodburn, N. S. W., Sept. 19.

TURNING FRAMES

BY R. F. HOLTERRMANN

Dr. C. C. Miller gives me permission to go through “three motions in place of one in turning a frame over.” Probably he is like myself, and has never attended a moving-picture show. Let me ask Dr. Miller how he can turn a frame sidewise with *one* movement? What is *one* movement? Is a circle drawn out of one line? How many straight lines are there in a circle?

However, doctor, I was not addressing you. When people have kept bees as long as you and I have I suspect that combs can be held in any position with safety, especially when the combs are allowed to stay in the hives until the bees themselves chew down the walls and rebuild them. Even in our climate it is not safe to hold new comb

Harvee wrought by the great Louisiana hurricane and flood. Everything in the apiary destroyed and the bees drowned. The owner, J. D. Bailey, of New Orleans, to reach his ranch, went by boat a mile and a half over what would ordinarily have been dry ground.

filled with honey, pollen, and brood side-wise, and, after cheerfully allowing every one to do what he can do—any way, without my permission. I think the safe advice to give is, not to hold combs on their sides "in this locality."

What Dr. Miller writes on the same page

about good and bad qualities transmitted in breeding I quite agree with. Where good and bad traits are mixed, the fruit is mixed, uncertain, with probably a tendency to deterioration. Good fruit can be obtained in nature only by weeding out bad tendencies.

Brantford, Canada.

AN APIARY IN THE RECENT GULF HURRICANE

BY J. D. BAILEY

Our loss in the terrible storm that visited this section Sept. 29 has been complete, nothing being left out of a well-established apiary of sixty ten-frame colonies except two found floating. The roof of our honey-house was carried away, and some of the hives were found in the swamp a great way off. Nothing was left standing, as the water rose to a height of five feet within thirty minutes. The wind blew 85 miles an hour, and for the period of one minute attained a speed of 120 miles. The lowest barometric record ever taken by the Weather Bureau since its existence was recorded at 28.11.

It has been estimated that 350 persons lost their lives, and the damage runs up into the millions of dollars. I had a splendid

Wild bees from nearby trees cleaning up the job. No. 54 contains what is left of a strong colony found floating.

crop of honey in the hives, and was contemplating extracting last week. Two years

Rollers cleaning up after the flood.

of hard work has also been swept away; but I feel satisfied when I consider that our old keeper did not lose his life. The only thing that saved his house was the water, that rose to a depth of over two feet on his floor, keeping the wind from getting under the house. I am starting all over again: but the situation does look discouraging. I had a hive at home used for experimental purposes; but that, too, was lost. Not an orange or pecan remains to tell the tale. It will be a long time before the country regains its normal condition.

New Orleans, La.

WHERE THE QUEENS QUAHK

BY A. TSCHOEBERLE

Mr. Doolittle asks the question, page 750, Sept. 15, "Did any of the older heads ever hear a virgin queen pipe or quahk in any other place than the combs of the hives where there were rivals among these queens?" In answer I must say yes.

A year ago last June I had nine queen-cells and no nuclei for them; so I thought I would put them in cages for two or three days till I got time to make some nuclei. I caged and put them into the upper story of a strong hive, and two days later I could hear the young queens piping and quahking. The next day I opened the hive to see how many there were hatched. All nine were out. That evening I went over to listen, and I could hear the queens piping and

quahking. One would start piping and you would think all the rest would answer by quahking. The next day I took them out and looked through the lower part of the hive to see if there was any signs of queen-cells, but there were none.

Now as to the piping before the after-swarm, you can always go by that. This last summer I had two hives standing close together, and both of them swarmed the same day. Then I concluded I should let them go until they commenced piping. I went over every evening to listen, but I never could hear one piping or quahking. When I opened the hive there was only one young queen in each.

Marysville, Wash.

A NOVEL PEAR-BLIGHT REMEDY

BY J. C. GRAHAM

About two squares from my home there is an orchard of about 200 pear-trees belonging to a friend. In the opposite direction a friend has one pear-tree in his front yard. Two years ago the orchard and the single tree were badly affected with pear-blight. I told each friend of a remedy I had seen tried. The man with the single tree tried my remedy; but the other laughed at me. Last season the orchard was in a worse condition than the year before; but the single tree was in much better condition. This season the single tree is free from blight. The orchard is about a third dead, and the rest is in very bad order.

I suppose you too will be skeptical, but please try the remedy before you laugh. It

is nothing more than this: Drive 8 or 10 nails into the body of the tree; and, if not completely cured, as many more the next season. You will find that the nails will disappear and the head will drop off. The sap takes up the iron as it rusts, and the blight simply does not come back. I don't pretend to know why, but have seen it tried again and again, and find it will work.

One other thing: When my bees can fly in the spring, when the orchard referred to above is in bloom my friend has a nice crop of fruit. When it is too cold for the bees to fly when the trees bloom, he has no fruit. I have been living here eight years, and this has always been true.

Mayfield, Ky.

A motor cycle and side car are inexpensive to run.

THE MOTOR CYCLE FOR APIARIAN WORK

BY L. A. P. STONE

I use a motor cycle and side car instead of a light automobile. Recently I had an automobile, but the cost of upkeep more than overbalanced its usefulness. The cost of running the motor cycle and side car is slight, and there is very little trouble. The motorcycle will carry 200 pounds besides

the rider. I use it mostly in distributing honey.

There are only three tires to get punctured, and one cylinder to get out of order. Even this never does if overhauled once a year. Moreover, I can run sixty miles on one gallon of gasoline.

I do not believe very many one - cylinder motorcycles will pull as much as mine, as my make of machine is more powerful than the majority.

The side car was built to order, and has a platform 35 by 25 inches. The platform is mounted on light springs so that it is more comfortable to ride on than the saddle of the motorcycle. In fact, I prefer to ride on it instead of the saddle when the side car is not loaded, because I avoid all chances of tipping over when going around turns or along

The cycle will carry 200 pounds, exclusive of the driver.

slanting roads. The side car is very light (weighs about 75 lbs.), and its width is not quite that of the track in the road, which, however, makes little difference on an ordinary road.

My apiaries are scattered, and all away

from home, so I save a great deal of time by using a motor cycle, and also a lot of expense by using it instead of an automobile. Of course, if I have heavy hauling to do I hire a team; but this is not very often.

Erie Beach, Ont.

HOW TO OBVIATE ALL TWIST WHEN PUTTING HIVES TOGETHER

BY C. E. FOWLER

I bought a deep super for a sample; and after nailing it together I found it twisted 1-16 of an inch. Now, if I put it on top of another super that is twisted as badly in the opposite way, and three corners touch, there will be an $\frac{1}{8}$ -inch opening at the fourth corner. The twisted hive seems to me the great bugbear in home-made hives.

Of course you can use your eye; but I wanted something more accurate, and something that could be used by unskilled persons; so I studied the matter over, and found that if three straight boards form a triangle, every part of this triangle is in the same plane. I made my triangle three feet on a side, of $\frac{1}{2} \times 3$ -inch pieces. If you place this triangle on top of a hive, one side of the triangle on one side of the hive, the other two sides of the triangle will touch the two opposite corners of the hive. If all your edges of the triangle and hive are straight, and the triangle touches all four corners at once, your hive is absolutely true. You can use the same triangle on your bottom-boards, covers, frames, or any thing that has four sides to it.

If you are making many hives it would be better to have your triangle heavier (but of the same size—three feet), and resting on the bench, and to put your hives on top. You can use both sides of the triangle, and it makes no difference if the sides of the triangle are wider at one end than the other,

provided the edges are straight and meet at the corner. No matter how light it is you cannot strain the joints as would be possible if there were four sides.

If every hive is square and made the same size, half the battle is won.

If you make your own hives you can make them 1-16 or $\frac{1}{8}$ inch deeper than you need; and then, after they are thoroughly nailed, make the top true; then gauge each side and true up the bottom. Paint it before it gets wet.

Hammonton, N. J.

NET-WEIGHT REGULATIONS UNJUST TO BEEMEN

BY E. C. BIRD

The net-weight regulations, demanding that the net weight of each section of comb honey be stamped upon the top of each section, is manifestly unfair, onerous, and impossible to comply with. The basic principle is the same as though the farmer were required to stamp each ear of corn with the net weight, or the poultry-raiser to stamp the net weight of each egg placed on the market for interstate shipment; or that bananas be required to show net weight.

When a dealer has an order for eggs or

bananas he does not select for a dozen twelve of the smallest and least desirable ones, but with the nine or ten large and most acceptable ones adds a few of the smaller, so that on the whole he gives a proportionate share of the large and small. Now the section of honey, like the ear of corn and the eggs, is the product of nature over the thickness and extent of which the producer has no control. The bees may finish it in any conceivable variation of weight from 10 to 18 ounces.

Again, the demand for honey includes the neatness, delicacy, and attractiveness of the article more than the weight of a certain portion. The market demands that it be cased so that the white and well-finished sections shall be separate from those of darker or less presentable combs. Hence the combination of these two requirements, neatness and weight, makes so many varieties to case separately that it is impossible for the common workman to case honey

under this system. It causes the producer to procure expert and expensive assistants or to send his product by a circuitous route in order to have it properly graded at increased expense at some central grading-house.

These considerations should stir the comb-honey producers to combine for a more equitable market condition and to overthrow a system of grading which the public does not understand nor demand.

Boulder, Col.

NOTES FROM GERMANY

BY J. A. HEBERLE, B. S.

Honey, "the essence of all that is good," presents a great variation of color, aroma, and taste—mostly a combination of nectars from various flowers and blossoms. In America there are vast areas seeded to alfalfa, and at the time of bloom the bees will visit other flowers to such a small extent that we may properly speak of alfalfa honey. The same holds true for white clover, basswood, orange blossom, etc.

In Germany, with the exception of heather and the juice from a fir-tree, we harvest but small quantities of honey the nectar of which is chiefly from one plant—sainfoin, akazie, buckwheat, etc.

DANDELION HONEY.

Here in the extreme southern part of Germany, but a few miles from the Alps, we harvest a little honey from the dandelion, but all of it has some nectar from the fruit-trees and other flowers mixed with it. The color of dandelion honey is that of gold with a very decided aroma, and tastes rather strong, especially to those used only to mild honey. The taste is fine when mixed with the nectar of other flowers in such a proportion that the taste of the dandelion is not so very prominent that it has lost its pungency.

The honey is very viscous; and, if not extracted immediately, some of the combs will break—even old combs. I have seen it crystallize within 48 hours after extraction, although it had been only partly capped. By the way, this is the only variety of honey here that may be extracted before the combs are capped without losing quality. All the honey from other flowers, if extracted before capping, shows a decided inferiority in taste—something like a raw, unfinished product, and it does not keep well. However, uncapped honey may be extracted if no nectar has been coming in for some time when the surplus water has

been evaporated, and the bees have ripened the honey, but for lack of nectar have not capped it.

Dandelion grows here in great profusion, especially in fields that have a few years before been cultivated with the plow. The country appears during the second half of May like a chessboard in gold and green. It begins to bloom here between May 10 and 15, and lasts for two weeks. Some flowers are seen at the end of April, but they are not numerous enough to be of importance. The pollen, which it furnishes in great quantities is of orange-yellow color.

The great drawback is, that this early in spring most of the colonies are not at their best, and the weather is very unfavorable. It is cold, and much rain and wind prevail on account of the nearness of the Alps and the elevation of the country.

The country here is a natural pasture. The meadows are not excelled anywhere. The secretion of nectar from a great variety of plants from about the middle of May till the end of June would be good, and the quality of the honey excellent; but the weather does not favor the beekeepers. Usually in this immediate vicinity about July 1, the honey harvest is over. What the bees get afterward they need themselves, and usually a few pounds of sugar has to be fed in the fall to provision them amply till the following spring. Some years (the exception) bees may store surplus in July or the first of August, depending on the weather. Considerable difference may be noted of apiaries only a mile or two apart, depending on the configuration of the country—a protected valley, for instance—"locality." Oranges may do well on a hillside, but freeze on land only a few hundred feet further down.

THE HONEY CROP IN GERMANY.

From reports of different parts we may

say that Germany's honey crop this past season has been above the average. In some parts it is good, and even very good; in some, on account of drouth, it is but fair. However, a good crop in California differs greatly in the number of pounds per colony from what is called a good crop in Germany. Here we have places where an average of 20 lbs. per colony is considered very good. Only rare places may in an extra good season bring as much as 100 lbs. per colony by migrating with the bees.

TWO-STORY HIVES FOR WINTERING

BY J. M. DONALDSON.

Wintering over a set of empty combs has been my way of wintering in three widely different localities. In two of the locations I used winter cases, but here in central New Jersey the added protection does not make enough difference in wintering to justify the extra cost and labor.

Ten years' experience in this location has taught me that colonies with young queens and plenty of good stores if wintered in two-story hives will come out good and strong in the spring. Some who winter bees in the cellar or in well-packed winter cases may wonder what advantage there is in using two stories if the lower set of combs are empty. There are several advantages. Mr. Hill names two of them when he says that the lower set of combs acts as a windbreak, and that the bees are not so apt to fly out on bright cold days.

I do not consider a one-story hive deep enough for the bees to store enough honey to carry them safely through the winter and have enough left so that brood-rearing can go right along till honey and pollen are coming in, and at the same time keep up late brood-rearing, so there will be a large force of young bees to winter. With a two-story hive the bees can crowd the queen clear out of the upper story, but she will still have that lower set of combs for a brood-nest. Should the upper set be entirely filled and sealed down to the bottom-bar the lower set makes an ideal clustering-place until some of the honey is consumed and the winter nest formed in the top story. When the queen begins laying, the brood-nest will be in the upper story, and the first examination of the colony can easily be made without unsealing the cover by simply tipping up the top story. When the queen has expanded the brood-nest so that there are five or six frames of brood, the bodies should be shifted, the queen being used in the top story, as her brood-nest will soon

HONEY BY PARCEL POST.

Much honey is sent here by mail. Eleven pounds from one end of the empire to the other costs but 12 cents; and if the distance does not exceed 60 miles the charge is but 6 cents. I send only crystallized honey through the mail, so no damage has ever occurred by the roughest handling. The cans used differ from the common gallon can with screw cap. They are round, with a well-fitting cover that can be taken off.

Kempton, Bavaria, Germany.

occupy the empty combs if a frame of brood is put in when the shift is made.

The editor thinks there would be danger of mice getting in and destroying the lower set of comb. I did not think so; but when I had bottom-bars gnawed almost in two, and whole sets of combs destroyed, besides having the bees disturbed, then I knew for a fact that there was danger. I now use an entrance-contractor with frame-spacing staples driven in the opening.

Would honey left in the lower set of combs in the spring invite robbers to enter? I don't know, because honey is seldom found there, even if there was quite a little when winter set in. I have always had an idea that the set of empty combs discouraged robbing. It's a long way from the entrance to the honey; and if robbers should succeed in entering they have the same road to travel again before they can spread the news.

Moorestown, N. J.

THANKSGIVING

BY GRACE ALLEN

Across the land I hear a noble strain,
A mighty song, triumphant, of thanksgiving,
A proudly grateful hymn sung not in vain
So it but stir a chord of larger living.
And may my voice commingle, as I strive
A low, full-throated, yearning note to sing;
Give thanks, O hosts, for honey in the hive,
But let me lift my song
To celebrate the long
Courageous quest and uncomplaining wing!

Give thanks for harvests, aye, and join me then
In thanks for labor of undaunted men.
Rejoice for vict'ries won for truth and right,
And then rejoice in hearts that fight the fight.
Full thanks we yield for peaceful blessings streaming
Across our lives, with glimpse of dream come true;
But most of all I prize the very dreaming,
And some slight will to do.
Our thanks then, God, for dreams that dare to soar,
And faith that thrills to work. And grant us more!

Heads of Grain from Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

Now's the time of year when folks begin to think about buckwheat cakes and home-made sausage. Pass the honey, please.

Some York State Notes

Clover was scarce in the spring, but now I wish you could see it. The fields and woods are a bed of it—white, alsike, and crimson. Next year should be one of the greatest honey years we have ever had if the clover does not winter-kill. I still have the supers on the hives, and they are crowded with bees. The queen is laying to her full capacity.

I have thirty colonies, of which only four cast a swarm this year. To prevent swarming I divide by the Alexander plan. I place the queen in the lower part of the hive and set the old hive on top; and when the brood is all hatched I shake them in the hive with the queen. I find it almost wholly prevents swarming. This plan makes extra-strong colonies. I requeened all of my colonies in July and August, which accounts for my hives being full of brood and eggs at this time.

The crop of honey here has been only about half the average. This was owing to the late cold spring lasting until the middle of June. From that time until the present there have been very heavy rains. The bees were able to work about half time.

Introducing by the Smoke Method after Queen-cells are Built and Destroyed

I have learned some things about the smoke method of queen introduction that may be of interest to others. The first season I used it with good results, the second very poor; the third a little better; and

this year I have learned why the difference. Queens can be successfully introduced by the smoke method during a good honey flow, in a few hours after the old queen has been removed; but when no honey is coming in, the loss will be heavy; and as I do nearly all of my requeening after the main flow is over. I wait about eight or nine days after the old queen is removed. Then I tear down all queen-cells and run in my young queens with smoke, and get 100 per cent accepted. This is a little trouble, but not so much as giving two or more queens to one hive.

I have yet to lose my first queen given to a hive with laying workers when she is introduced by the Miller smoke method. I use three puffs of smoke to a single-story hive; six to a big two-story ten-frame hive, and nine if the hive is a three-story ten-frame.

I use planer-shavings in the smoker for this purpose, and find that they give better satisfaction than anything else I can get.

FINDING 35 QUEENS AN HOUR.

I should like to know how many queens a good operator can hunt up and clip in an hour in ordinary-sized hives. I have heard of one man who claimed to catch 35 in one hour. This is much better than I can do.

Montgomery, Ala.

J. M. CUTTS.

[Thirty-five queens an hour is "going some," even if the queens were in nuclei. We wish the one who has worked at that rate would tell us how he does it.—ED.]

Parcel-post Shipments Successful

We have made a successful attempt to ship extracted honey by parcel post. We sent a number of pails, and every one arrived all right. We shipped in friction-top five and ten pound pails, with the cover pressed down and solder run all the way round to hold it solid. The pail was then enclosed in a stout wooden case, so that, when nailed shut, it fit snugly.

We are going to try the small screw-top square can. If it will do as well (and we believe it will) it will save much tedious soldering.

The price realized for honey shipped in this way will be much more satisfactory than what we get from the wholesale buyer, and at the same time the housewife in the city gets it cheaper than she could at the grocery.

We shipped to Birmingham, which is in the second zone from us.

Folkland, Ala., Oct. 12.

SCHUG & DEWITT.

Wintering Bees Covered with Hay in a Barn

My barn has a light loft, and no battens on the siding around the loft, so it never gets damp or steamy. I put down about an eight or ten inch layer of hay, lay two boards on it, and set the hives on these boards close up to each other, having first put on supers and packed them with burlap and excelsior. Then I put queen-traps or pieces of queen-excluder over mouths of hives in a way to let in plenty of air and keep mice from getting in. I next set sticks, about eighteen inches long, slanting against the front of the hive, and cover with a layer of hay thick enough to keep out the light and drafts of wind, but not so thick but that air can go through.

Then I stack hay on the other side and each end and top of the row. It keeps out the noise, and keeps the temperature even. I live near the southern line of Minnesota, and put my bees in last fall about the last of October, in a part of the barn where the sun would not hit them. The last of March I took them up one fine morning and set

them in a new place where the sun comes in the hay-door in the morning and forenoon. I banked each end and back of the row of hives with hay and took off the queen-traps, and they had a good fly and clean-up, and were happy as a dusty traveler after a bath. Every day when it is warm enough I open the door and let in the sun; and when it is cold or windy I leave it shut. If they want to fly they go through the cracks.

Their hives were perfectly clean, and had very few dead bees in them. Our coldest weather last winter was 29 below zero one night, and 24° below two other nights. I am well satisfied with the way they wintered.

Sherburn, Minn.

D. M. REYNOLDS.

Remove the Snow from the Front of the Case during a Thaw

From my observations and a limited experience I am inclined to believe that, when there is an anticipated thaw, it is better to remove snow from the covers and ground near the hive or winter case. Any considerable bulk of snow allowed to melt undisturbed produces an excess of moisture about the hive. The slow melting by day and freezing by night tends to produce hard ice, which is very objectionable about the entrance and adjacent parts.

The direct rays of the sun upon the hive will, many times, bring the bees out while there is yet a depth of snow enveloping almost every available alighting-place, and the bees, not being fully adapted to outside conditions, fly about in a way not unlike Noah's dove, seeking some place whereon to rest her feet. Finding none, they drop, more or less exhausted, on the snow, soon chill, and never return to the hive. Had the snow been removed, the little that will remain is quickly melted and often out of the way before sufficient warmth reaches the bees to bring them out. Thus with a comfortable place on which to rest, the bees will be invigorated rather than chilled, and many more be able to make a safe return.

Barnesville, O.

THOMAS DEWEES.

Black Bees on Red Clover

We still have lots of alsike and white clover in bloom, and the bees are working on them when the weather will permit. Some one has said that bees work on red clover only in a dry season. I thought that might be the case, as my bees worked on it last season when we had a drouth, and this season has been very wet. Just once did I find the bees very thick on the red clover. Mine are not long-tongued red-clover bees, but just common blacks. How about this!

Decatur, Ind., Sept. 24.

W. W. HAWKINS.

Sealed Covers for Wintering

It does not always pay to experiment. When you have a sure thing it is well to stick to it. I found this out last winter. Having heard and read a great deal about giving ventilation to bees in winter quarters I resolved to give the thing a trial. I left on the hives the boards used with the bee-escapes. The latter were removed and a strip of screening tacked over the opening. On this I laid crosswise four sticks of wood and covered them with burlap. Then I put a heavy layer of straw over and around the hives, completing the job by placing a water-tight cover on top of the regular wintering box which I have been using for years.

Well, these bees wintered very poorly. Two colonies were dead outright, two others were queenless, and I did not take notice of it till May. Then they tore to pieces four good queens, which I introduced in the regulation way. By the time they had laying queens the season was well advanced. The remain-

ing colonies were of medium strength. But my whole apiary was queered by this experiment. It would have been a poor season anyway. This made it doubly so. Before this, with sealed covers, I had always wintered all of my colonies. They always came through in fine order, and gathered good crops, so I shall go back to the good old way.

One man's experience may not count for much; but the sealed cover has some doughty advocates—e. g., the editor of GLEANINGS. Even if this were not the case, I should say I care not what course others may take; but as for me—give me the sealed over every time.

Sees Laying Workers Lay

I have caught two laying workers in the very act of laying. The first time was about ten years ago. I had a case that baffled me. I finally went through the hive and selected the frame which had the most recently laid eggs. I held it in my hands for some time, and after a little I noticed a bee back into a cell.

I nabbed her, and there were the freshly laid eggs. I opened her and she had eggs in her body. I had tried to raise a queen in the hive by putting brood and eggs in the hive, but failed. After this I had no trouble in requeening the colony.

Just last year I had another case of the same kind. I tried finding the laying worker in the same way, but could not do so. At last I took the comb with the freshest-laid eggs and watched it for some time. Then I saw the bees clustering about one bee with their heads all pointed toward her. She was an old-looking bee, somewhat longer in the abdomen than the others. I killed her, with the same results as in the case above. I soon had a young queen in the hive.

In the fifty years of my beekeeping experience I have not always had such good fortune. I would suggest that the best way to oust the laying worker would be to open the hive, take out the frame with the freshest eggs, and put them in a separate hive. Nine times out of ten you will get rid of the laying worker. You can then raise or introduce a queen.

Leeton, Mo.

JOHN M. MOHLER.

Getting Ready for Winter in Arizona

I wintered fifteen colonies over a super of extracting-combs last winter. After the bees were done gathering honey in November I took off the supers and removed the brood-chambers from the bottom-boards. Then I set the supers that were almost empty on the bottom and set the brood-nest on top, so the bees could keep warmer during cold weather. Then I fixed the entrances with the entrance-blocks. The bees wintered finely. The mice never got inside of the hives. The moths damaged but one comb, which was in the side of the brood-chamber.

This fall I had twenty colonies—some three, some three and one-half, and some four stories high. Most of the combs are full of honey, pollen, and brood.

JOHN B. BUREAU.

The Amours of Apis Mellifica

A dog will look up in his master's face,

And knowingly wag his tail,

The man, answering back with a friendly smile—

At least it will seldom fail.

The way a *bee* has of making love

Is one of the strangest things;

It sits right down, gives its tail a tilt,

And gracefully wiggles its wings.

A. I. Root

OUR HOMES

Editor

Enter not into the path of the wicked, and go not in the way of evil men. Avoid it, pass not by it, turn from it, and pass away. For they sleep not, except they have done mischief; and their sleep is taken away unless they cause some to fall. But the path of the just is as the shining light, that shineth more and more unto the perfect day.—Prov. 4:14, 15, 16, 18.

I have always been busy. My mother said when I was but an infant I always found something to interest me and to be busy with. Almost sixty years ago, after I had become engaged to Mrs. Root I decided to start in business. I have told you there were two other jewelers in our little town of Medina, and the two at the time were almost "one too many." There was some merriment about my starting a *third* watch-repairing establishment. I borrowed a ladder, hung up my sign on a suitable post in front of the window of a vacant store; and before I got down from the ladder I had a job of cleaning a watch; and I do not believe I have ever been out of a job since that time. In fact, I tried so hard to keep up with my work I was soon obliged to work evenings as well as all day; and when I had been in the business barely ten years my health began to fail, in consequence of working so many hours indoors. A doctor in a nearby drugstore, with whom I was well acquainted, suggested that a glass of beer, say every day, or when I was worn out, might be a help. Now, this doctor was a good Christian man, and he was honest and sincere in thinking the *beer* would be a benefit. How many doctors are there at the present day who would give the same advice? If you know any such, try to persuade them that they are a relic of a former age.

Well, between my place of business and my home there was a saloon. They did not call it a saloon then—it was a grocery; but the grocer kept beer among other commodities. I finally got in the habit of having a glass of beer when I was tired and worn out, and needed rest and sleep. As the doctor said, it *did* seem to brace me up a little, for the time being. There was quite a stir in regard to temperance matters, however, even as long as fifty years ago; but as I always took my drink usually after nine or ten o'clock, nobody knew much about it.

Well, I remember one evening, when I came into the grocery, a man who just taken a drink looked at me in surprise and said, "Why, I didn't know that Mr. Root ever drank beer." I knew this was a sort of clip at me, and I felt a little guilty; but

the reply of the grocer was a still more *severe* clip. It was this:

"Oh! Mr. Root is one of my regular customers."

I went out and went home; but I kept hearing ringing in my ears, "Regular customer! regular customer!" My wife probably knew of my glass of beer; but as she was of English parentage she probably did not feel much worried, for people did not look at such things then as they do now. The claim that I was a "regular customer" was, of course, an exaggeration, and I hardly need say to the friends that the saloon-keepers have been for the *whole fifty years* that have elapsed since the incident mentioned, guilty of *exaggeration*. This matter of exaggeration reminds me that at one time, years ago, a statement came out in the papers that Mark Twain was *dead*. Finally one of the reporters of a daily paper called his attention to it; and with pencil and notebook in hand he said, "Mr. Twain, what have you to say to this? What shall we tell the people about it?"

I think Mark looked at his interlocutor a little while, and with a little smile on his face replied, "Just say for me that the statement is *greatly exaggerated*."

Before I take up the subject of exaggeration, however, I wish to say a word or two about the doctors of the present day who advise beer for men and women who are run down because they stay indoors so much, or eat three meals a day when two would be a great plenty, etc. The whole wide world now is ringing, as I have told you repeatedly, with the slogan of "efficiency;" and this whole wide world is also not only declaring but *insisting* that alcohol in *any form* and in *any quantity* is a foe to efficiency. Insurance companies, railroad companies, manufactories, and everybody else demand men and women, boys and girls, who do not drink *at all*. Any drink that contains alcohol in any quantity whatever is tabooed; and whisky and brandy are ruled out as medicines; and the time is soon coming when doctors are going to cure people without booze, without stimulants or dope, and without stuff that comes in bottles. Twenty years ago Dr. Dewey published a book that made quite a sensation at the time, declaring that drugs and medicines are not needed, even in cases of typhoid fever; and he gave a long list of typhoid patients who were cured quicker and were left in better shape where they had no medicine whatever. We may thank

God that a periodical of such authority and such wide circulation as the *Ladies' Home Journal* is giving us some "hot shot" along this line. Here is a clipping from their October issue:

THE PASSING OF THE MEDICINE BOTTLE.

We are certainly making long strides forward when we read such words as these, and they concern us all because they concern our health. And it must be well borne in mind that the writer, Sir William Osler, M.D., is unquestionably the foremost living American physician, and the highest authority on drugs in the medical world. He says what follows, in the *Encyclopædia Americana*:

"The new school does not feel itself under obligation to give any medicine whatever, while a generation ago not only could few physicians have held their practice unless they did, but few would have thought it safe or scientific.

"Of course there are still many cases where the patient or the patient's friends must be humored by administering medicine, or alleged medicine, where it is not really needed, and indeed often where the buoyancy of mind, which is the real curative agent, can be created only by making him wait hopefully for the expected action of medicine; and some physicians still cannot unlearn their old training.

"But the change is great. The modern treatment of disease relies very greatly on the so-called natural methods, diet and exercise, bathing and massage; in other words, giving the natural forces the fullest scope by easy and thorough nutrition, increased flow of blood, and removal of obstructions to the excretory systems or to circulation in the tissues.

"One notable example is typhoid fever. At the outset of the nineteenth century it was treated with 'remedies' of the extremest violence—bleeding and blistering, vomiting and purging, antimony and calomel, and other heroic remedies. Now the patient is bathed and nursed and carefully tended, but rarely given medicine.

"This is the result of the remarkable experiments of the Paris and Vienna schools into the action of drugs, which have shaken the stoutest faiths; and partly of the constant and reproachful object lesson of homeopathy. No regular physician would ever admit that the homeopathic 'infinitesimals' could do any good as direct curative agents; and yet it was perfectly certain that homeopaths lost no more of their patients than others. There was but one conclusion to draw, that most drugs had no effect whatever on the diseases for which they were administered."

Now let me go back a minute to give the Woman's Crusade, that started here in Ohio in the early spring of 1874, a little credit. If I remember correctly, Dr. Dio Lewis first made the suggestion that the mothers of our land should meet in a body together and invade the saloons. A lot of Ohio mothers did this. They went into the saloons here in our town of Medina, expostulated with the saloon-keeper, sang hymns, and finally knelt in prayer on the filthy sawdust floor. When I heard what was going on I hesitated about going into a saloon for any more drink. Even though I did not go to church at the time—at least not very much—I had a reverence and respect for those earnest, faithful, God-fearing women, and I broke off then and there, and soon decided that a little more outdoor work in the garden

would be a better tonic than booze. I think I used to get Kennet ale at the drugstore occasionally; but the way people stared at me to see me drinking something that looked like beer, even in a drugstore, made me feel I was not doing exactly the right thing. In fact, I one day overheard a small boy telling his mother something like this: "Mr. Root drinks beer. I saw him drink some in Dr. —'s drugstore." There was no use of explaining that I took it for medicine. Public opinion, even that many years ago, was fast climbing up on the right side. Now a word about exaggeration:

The Cleveland *Plain Dealer*, from which I have quoted so much, has now a couple of the opposite column against it. Well, I have been amused at the pleas on the wet side. It seems to me, to use a slang phrase, the writer is continually giving himself away. As an illustration:

The wet writer said if Ohio votes dry, 140 places of business now occupied by saloon-keepers would be vacant. He said there were already enough rooms in the city labeled "For Rent," and if 140 more were added, rents would go down all over the city, for two reasons—first, because there would be an oversupply of vacant rooms; second, because no one could afford to pay the *price* for rent that a saloon-keeper can. I presume the latter may be true; but is it not a rather *sad* truth? And then he goes on to tell the enormous amount of money that would be lost if the saloons were closed. Now, this writer was either purposely or ignorantly "lame" in ever so many directions, for towns and cities that have gone dry all over the United States are giving notice that the empty rooms are soon taken for better business and at better prices. And is it positively certain that it would be a calamity to have rents go down? The liquor people are continually declaring that the money that saloon-keepers do not get is *lost*. If rents go down, the owners of buildings, who are mostly wealthy men, lose a little. Now, wherever there is some loss there is generally a corresponding gain. The renters are usually poorer people, and to have their rents *reduced* would be a gain to those who most need it. Let me illustrate:

Every fall, when I go down to Florida, eggs are away up. A year ago, for a few days I got 60 cents a dozen; then after awhile, when the hens got over moulting, the price began to go down. One day last April, when I brought my eggs to the grocer he said, "Mr. Root, I hate to tell you, especially as you are such a good and reg-

ular customer, that we are overstocked with eggs. I do not see how we can allow you over 15 cents a dozen." But I laughingly replied, "Why, Mr. Burnett, you need not feel worried at all. I just enjoy the fun of selling eggs at 15 cents a dozen. You see, what is my loss is somebody else's gain; and poor people who have been finding it hard to meet the high cost of living now have a great plenty of the best and most healthful food in the world so cheap that the whole family can live on eggs if they wish to."

The whole plea about vacant stores, people out of employment, etc., is just what Mark Twain said about the report of his death—it is "greatly exaggerated."

On page 912 of GLEANINGS for October 1 I gave you a number of illustrations showing how the claims of the liquor party were "greatly exaggerated." Suppose, dear friends, I had kept on getting a glass of beer every night after dark, when I was tired out after a day's work. Suppose I had followed it up for fifty years. This is a ridiculous supposition, however, for I

probably should have been dead and gone (like the doctors) years ago. While I write these words on election day, Nov. 2, I feel so spry and so well I have been thinking I should like to take a foot race with some of my grandchildren—with Ralph, for instance, one of the Boy Scouts. He is about a dozen years old, and I rather think I could beat him now on a short run.

Now notice where the first one of my texts comes in, and the last one—"But the path of the just is as the shining light, that shineth more and more unto the perfect day." This illustrates why I thank God for having permitted me to live and be in touch with, and have a place with the best men and women of the present day. I am thanking God that he has enabled me to have a voice in pleading for temperance, righteousness, and purity as I have been doing for months past. And if I should be permitted to live long enough to see Ohio dry, I shall feel like saying with Zacharias of old, "Lord, now lettest thou thy servant depart in peace, for mine eyes have seen thy salvation."

TEMPERANCE

Today, Oct. 28,* while I dictate these lines before starting for Florida, and before election, nobody knows what the outcome of our voting here in Ohio will be; and of course the following clipping from the *American Issue*, when it comes before you, cannot affect the outcome of our Ohio election; but it *can* effect the elections that are to be held in the other states over the country. The clipping is headed, as you will notice, "A Startling Comparison." And indeed it is startling. As I read it over I pondered and wondered how it is possible, with these sights staring us in the face, we have put up with it, all these years since Lincoln's death. Read it, dear reader, over and over again. Read it to your wife and children, and explain its influence. Make

them understand that permitting the traffic to go on as it has been going on is worse than war, smallpox, bubonic plague, or any thing else in the whole wide world. May God help us. Here is the clipping:

A STARTLING COMPARISON.

The June, 1914, bulletin of the Ohio Board of Charities and Corrections gives a statistical report which shows a full year's experience of all Ohio counties with and without saloons. For that full year there were 45 dry and 43 wet counties. Separate the counties into two groups, the wet and dry, and tabulate the cases of crime, incorrigibility, and jail experience, and take into account that the wet counties have three times the population of the dry counties. This is the result:

The 45 dry counties sent to the Boys' Industrial School during the year.....	76
The 43 wet counties, entitled by population to send 228, actually sent.....	260
The 45 dry counties sent to the Girls' Industrial Home at Delaware.....	31
The 43 wet counties, entitled by population to send 93, actually sent.....	89
(With large unreported number from Cleveland to add to wet side.)	
The 45 dry counties sent to the Ohio Penitentiary	106
The 43 wet counties, entitled by population to send 318, actually sent.....	609
The 45 dry counties sent to the Mansfield Reformatory	83
The 43 wet counties, entitled by population to send 249, actually sent.....	582
The 45 dry counties sentenced to work-houses	118
The 43 wet counties, entitled by population to send 354, actually sent.....	967

* The outcome of the Ohio election, as probably every reader of GLEANINGS knows by this time, was a victory for the wets. The prohibition amendment lost by a majority of a little over 57,000. With all the votes counted, the dries found they had been defeated by a majority of 30,000 votes less than the majority which defeated the similar amendment last year. Fortunately for the cause of prohibition, the wets' proposed amendment entitled "Constitutional Stability" was overwhelmingly defeated. This provision, if it had been passed, would have made it impossible for the dries to bring a vote upon statewide prohibition within six years. It is not probable that this notorious measure will be heard of again. The majority which defeated prohibition this year came, as last, from Cincinnati.

The 45 dry counties sentenced to jail imprisonment	497
The 43 wet counties, entitled by population to send 1491, actually sent.....	2646
(With Cleveland not reported to add to wet side.)	
The 45 dry counties expended for maintenance of jail prisoners	\$21,316.06
The 43 wet counties, entitled by population to \$63,948.18, actually spent.....	\$139,750.07
(With Lucas and Clarke, cities of Toledo and Springfield, not reported, and yet to add to wet side.)	
Cost of jail prisoners in 45 dry counties one year	\$21,316.06
Same in <i>Hamilton County alone</i> , with only one-third the people.....	\$21,037.90

This shows that the presence of the saloon doubles and trebles the disorder and crime with its consequent expense to the taxpayer. It is to be noted that the cost of criminal prosecutions is much greater in wet counties.

Nothing is wanting to show the benefits enjoyed by the dry counties; but when you consider that Ohio dry counties have the disadvantage of wet neighbors, and that the wet counties have more than half their territory dry, the above contrast is not only startling, but it amounts to *absolute* demonstration.

OUR FARM PAPERS AND OUR CLASS JOURNALS; THE STAND THEY ARE TAKING AGAINST BOOZE.

For the past six months it has been my privilege to glance over hastily toward a hundred periodicals that come to our office in exchange for GLEANINGS; and it rejoices my heart to see that almost every periodical—in fact, I might say *every* one (except some of our great city dailies and a few others) comes out with bold editorials for prohibition. Let me give you a sample. This comes from the *Fruitman and Gardener*, Mt. Vernon, Iowa. See what the editor says:

CLOSING THE SALOONS.

It is interesting to note the gradual closing in on the saloon by the anti-saloon forces. A little here, a little there, once in a while a step backward, but almost always a step in advance. It is literally trench fighting—hand to hand conflict.

It is also interesting to note who is the most able assistant of the temperance forces. Their most able assistant is the saloon-keeper himself.

This is noticeable everywhere the fight is on—nowhere more than in Chicago just now. In that city Mayor Thompson issued an order that the state law should be enforced. This meant Sunday closing of saloons. With what result? Mass meetings were held, and the keepers of the saloons decided to disobey the law. They seemingly thought that in their numbers there would be sufficient influence to overcome the law.

The saloon-keeper seems to be a natural-born hog. He never seems to know when he is well off. He is always grasping for everything in sight. This is his undoing. It was his undoing here in Iowa, where his partisans attempted to block all legislation on the subject, although they were in a small minority. It has been his undoing everywhere. Here in Iowa the opponents of the saloon turned and closed all saloons in the state—something they would not have done for a number of years had they not been goaded into it. And the opponents of the saloon in

Chicago will eventually get a tighter hitch on the saloon because of the action of the saloon-keepers.

The italics in the above are my own. It is a little tough on the saloon-keeper, I know; but the point is that just now no man will go into the saloon business and pay for a license unless he is one of the lowest and most depraved specimens of humanity—one who is willing to brave the scorn of his fellow-men, including the women and children, just because he thinks here is an opportunity to "get rich quick."

The above clipping suggests that the saloon-keeper himself is going to be "the most able assistant of the temperance forces." The following, also from the *American Issue*, illustrates this point. To understand it you want to consider that after that dry Sunday in Chicago the saloon-keepers (7152) came out with a big wail, saying they had lost \$400,000. When I read it to Mrs. Root, she said, "Why, my dear husband, you are certainly making a mistake. You mean \$40,000." But I took another good look and found it was the same in all the papers.

Saloon-keepers in Chicago positively declare they lost \$400,000; and a *thousand or two* have declared they would go out of business if they could not have *their best day in the week* for trade. The poor fellows in this wail evidently expected to get sympathy; but that is where they put their foot in it. A lot of people in Chicago were like Mrs. Root—they could not believe it possible that toward half a million dollars went for booze every Sunday in Chicago, and perhaps it is not true—we hope so. They tried to make out, as usual, that this sum of \$400,000 was *lost*—that is, *they* lost it, and may God be praised that they did "*lose*" it. Yes, stupidly as usual, they forgot that what was *their* loss was a gain for *somebody else*. Now read the clipping I have been talking about:

DRY SUNDAY HELPS BUSINESS.

One incident in connection with Chicago's new experience of worrying along over Sunday without taking its nip, or a multiplication of nips, ought to be of particular interest to the merchant. We refer to the report from that marvelous department store, Marshall Field & Co. The management is reported to have said that they did the biggest Monday business in their history, following the second dry Sunday.

The saloonkeepers (7152) themselves say that they lost \$400,000 as a result of the dry Sunday. This wail, read in the light of Marshall Field's report, gives a hint as to how to divert into legitimate channels money that is now being worse than wasted.

Close the saloons.

Please notice that quite a part—perhaps a large part of that \$400,000—went to other great establishments for household sup-

plies as well as to the drygoods store of Marshall Field & Co. Thousands of families, perhaps greatly in need in a great city like Chicago, have now the necessities of life because of that closing on Sunday. Dear reader, can you not see and rejoice with me that God's kingdom is coming?

Just after I dictated the words above, there was handed me the following, clipped from the Akron *Beacon-Journal*:

PRICE OF DRINK VARIES FROM DIME UP TO DAMNATION; FORMER COUNSEL FOR WETS SCORES LIQUOR AT DRY MEETING.

Trenchant utterances against the liquor traffic were unloosed by Dan Morgan Smith, former general counsel for the National Model License League, but now aligned with the Anti-saloon League.

"The price of a drink ranges from a dime to damnation," said Smith. "The purchaser pays the dime when he gets the drink, and the damnation when the drink gets him."

"The price of drink ranges from ten cents to unpaid rent bills, unpaid grocery bills, unpaid doctor bills, foreclosed mortgages, protested notes, lost positions, hungry children, broken-hearted wives, and corrupt government.

WHY SALOON STAYS.

"The saloon has been tolerated in this country, not because it was a working man's club, not because of the taxes it pays, not because the public demands it be licensed, not because it fills a great need, but because some church members pray for their state to go dry while they vote for legislators whom they know will keep it wet."

Smith scored the moderate-drinking argument. "The moderate drinker of today is the drunkard of tomorrow," he declared.

Does not the above represent the opinions of all the advocates of the wet side?

We clip the following from the October issue of the *Independent*:

From 1860 to 1907 there was a very rapid increase in the consumption of alcoholic liquors, beginning with six and a half gallons per capita and reaching nearly twenty-three gallons per capita. Then for several years there was little change, and, indeed, a slight lessening of the per-capita rate. This, of course, was due to the increase of prohibition territory. Now, for the first time there has been a great downward swing, and a falling off in consumption of 15,000,000 gallons of distilled spirit and 6,358,744 barrels of beer in one year.

When somebody tells you that the consumption of liquors is now on the increase, just point him to the above.

DOES PROHIBITION KILL BUSINESS?

James R. Hanna, mayor of Des Moines, Iowa, furnishes an article as follows:

"I have to report that our first eight months' experience has in every way been immensely beneficial. The fear of many that business depression would follow the closing of saloons has not been realized. Practically all desirable places were almost immediately occupied by other lines of business. The money which went into the channels of the liquor trade has gone into the channels of legitimate business. Our expenditures last year for liquor were estimated at about \$2,000,000, and careful tabulation of shipments so far this year are estimated at about one-tenth of that amount. This \$1,800,-

000 difference is going to pay for groceries, fuel, clothing, lumber for home-building, payments on town lots, and a thousand other things making for the welfare of those who bore the burden of expense in this business.

"It is nonsense to argue that a city of 100,000 can throw away \$2,000,000 each year for something that in no way conduces to the actual needs or comforts of life without paying the penalty. Our police records, court records, inebriate records, pauper records, and charity records all show this clearly, thus early. The superintendent of our public schools reports a decided improvement in the dress, attendance, and the efficiency of the large class of pupils from families affected by the liquor business. —Ashland Times-Gazette.

JOHN L. SULLIVAN, THE CHAMPION PRIZE-FIGHTER—SEE PAGE 779, SEPT. 15.

In the *Outlook* for Oct. 27 we see a full-page illustration of John L. Sullivan "clothed and in his right mind." Underneath the picture we read as follows:

The one-time champion pugilist has just signed a five-year contract to speak against John Barleycorn and all of his works, in every part of the United States. From being an advocate and frequenter of the saloon Sullivan has become one of its most influential opponents.

The magazine also contains quite an editorial in regard to the emancipation and transformation of our good friend John L. Sullivan. Sometimes we hear it said that the day of miracles is past; but is there a greater miracle than a man like Sullivan, who stood the greater part of his life almost at the head of the bad element of this world, now transformed into an evangelist for righteousness? Take a look at his picture in the *Outlook* and thank God that, by the power of the gospel of Christ Jesus, even the leopard "may change his spots."

A KIND LETTER FROM A LADY BEEKEEPER AWAY OFF IN NEW ZEALAND.

Dear Mr Root:—I am a young lady beekeeper, and read GLANINGS regularly. I have about 80 colonies at present, and use a Ford car to get to and from the apiary, which is over 40 miles from home. I have used a four-frame hand extractor previously, but am getting a power one this season. I can do all the work of the apiary except heavy lifting, for which I get an assistant at the busy time.

Our young men are going in large numbers to the war, and being killed. Lists of killed and injured appear in every paper. One wonders what will be the end of it all.

We are holding a beekeepers' conference in Wellington, in the North Island, in June. We beekeepers away in this corner of the earth send you our kindest regards, and trust you will be spared many years to continue your good work in the Home papers.

MABEL SHEPHERD.

Christchurch, New Zealand, May 24.

[We are very glad to get a letter from a lady beekeeper, especially from one so far away; but it saddens me again to think that away off in New Zealand the war is taking its toll of death and destruction, and accomplishing nothing after all. May God help us.—A. I. R.]

HIGH-PRESSURE GARDENING

SPINELESS CACTUS IN FLORIDA; OUR SPINELESS CACTUS IN OHIO.

Fly comparing the picture below with the one on page 825, Oct. 1, it seems quite evident that spineless cactus makes a better growth here in Ohio than it does down in Florida, especially in Florida in summer time. I presume so much wetness in summer is bad for cactus in Florida, but I think the wetness here in Ohio during the past summer is pretty nearly equal to that of Florida, especially in the frequency. The Florida cactus was planted last March, while the Ohio cactus was not planted out till July. I told our good neighbor, Mr. Harrison, to place some object near the plant so our readers could judge correctly of its size. I presume I should have done so with our Ohio plant.

SOME OF THE SPINELESS CACTI, AND A GLIMPSE OF OUR FLORIDA GARDEN.

My good neighbor, Mr. Harrison, is a fair illustration of the wonderful results of our climate on old people. I believe Mr. Harrison is about 80 years of age. The picture also illustrates the way sweet potatoes and yams grow when they once get started. In the background, right back of Mr. Harrison, is a specimen of the dwarf poinsetta in full bloom.

SPINELESS CACTUS IN CALIFORNIA—A GOOD REPORT.

Mr. A. I. Root:—I have been reading all you have said about cactus in the last few issues of

GLEANINGS, and would say that I have been propagating between one and two acres for several years, and find it the most interesting plant I ever cultivated. Chickens eat it readily, and it is good cooked; and if it is raised on quite dry land it tastes very much like currants. It should be eaten with cream or milk, and honey on it.

I think the reason those rotted (see p. 826, Oct. 1) was because they were cut from the old stock a little too early, which caused them to turn to sugary sap and become yellow in color. In this condition flies will blow or lay eggs in them, and they will be eaten by the fly larvæ.

Cutworms also eat the chits when they first start to grow if grass and weeds are allowed to grow among them. The cutworms should be dug out of the earth the same as where they eat cabbage or tomato plants. Army worms also work on cactus sometimes.

The ground must be kept loose by cultivation, and cactus will do well on the driest mountain land; but if not cultivated they soon fail. They do quite well without irrigation anywhere. As food it seems to be very healthful. I have about twelve varieties of the spineless, and two kinds of that having spines. I paid from two to five dollars per slab, and these have increased to hundreds.

I see no reason why cactus could not be eaten as much as bread or potatoes; and two or three square rods would furnish a large amount of food. The small spines or bristles on the fruit can be quickly brushed off with a whisk-broom. I also eat the fruit with milk and honey, and it tastes like strawberries.

Cactus slabs should not be cut from the old stock until it is about ready to put out shoots for new growth. Then they should be placed in a partially shady and dry place until they begin to start roots. Then plant in the field. They do well laid on the top of the ground without burying in the soil in planting.

Owensmouth, Cal.

C. W. DAYTON.

I take it from the above that the cactus slabs when cooked are fit to eat as well as the cactus fruit. If this is true it is quite an important fact in favor of growing cactus.

CACTUS AT \$15.00 A TON INSTEAD OF \$2.00 OR \$3.00 A LEAF.

Your cactus writings are interesting when you tell of paying over one dollar for a slab down in Florida. We sell it here by the ton. I should like to send you a few carloads at \$15.00 a ton. Several of our neighbors here have fed it to cows in place of ensilage, and they gave as much milk. I have one plant eight feet high, and this is its second summer's growth.

Lakeside, Cal., Oct. 18.

G. E. PHILEBOOK.

Thanks for your report, my good friend. The price of \$1.75 per leaf or slab is the highest I have paid. The plant I have in my garden here in Medina was advertised, I think, at \$4.00 to \$5.00 a leaf; and in about 90 days here in the North it has produced eight new leaves pretty well approaching the size of the parent leaf. Just now, October 23, I am blanketing it to protect it from frost until I pull to pieces the whole plant to take it down to Florida.

SWEET CLOVER IN KANSAS.

I hold in my hand a very important bulletin just sent out from the State Board of Agriculture of Kansas. It contains 38 pages in regard to sweet clover, illustrated with numerous cuts. From it I make two extracts:

The first is in regard to sweet clover for honey, and the second contains the important fact that cattle will eat the straw after thrashing out the seed. I think it has been several times mentioned that after cattle and perhaps other stock acquire an *appetite* for sweet clover they will eat with avidity the dry stalks after the leaves and seed have fallen off.

KANSAS SWEET-CLOVER EXPERIENCE.

Sweet clover is the best plant for bees I ever saw. Two years ago I sold 940 pounds of honey from sixteen stands of bees, besides what we used in the family and gave away. It was as white as white-clover honey, and tasted just as well.

I have tried it for pasture for cows by sowing it on alfalfa ground and disking it in. It prevents bloat, as the bitter taste of it, called coumarin, prevents bloat. I have used it for hog pasture. Hogs are very fond of it.

I use the yellow sweet clover. It does not grow as rank as the white variety, and is earlier. It commenced to bloom the last week in April and bloomed continuously until July 10. It will grow in the shade, and in places where alfalfa will not grow. It is a biennial, and dies out the third year; but if allowed to do so it will reseed itself. It is quite difficult to secure the seed, as it shatters so, and requires a huller to get clean seed. It will bear cutting the same as alfalfa, but must be allowed to seed itself the second year. It does not require the ground to be plowed. Disking and harrowing is all that is necessary.—JOHN W. WILSON in *Kansas Farmer*.

STOCK DEVoured SHREDDed STEMS.

When the sweet clover is permitted to seed, the stems are very woody and hard. I concluded before I thrashed the stuff for seed, the seed was all I would get out of it, and that I would have to let the dry leafless stems rot. There is where I was surprised pleasantly. I not only made a good profit from the seed, but the live stock ate those shredded stalks ravenously. Of course, the thrashing-machine tore the dry stalks to pieces—shredded them. The cattle seemed to enjoy it as much as ensilage.

As a pasture I know it is hard to beat. It will grow on land where alfalfa and red clover won't do well. But after sweet clover has been there a few years and thoroughly inoculated and built up the soil, red clover and alfalfa will do well.—H. L. DAWSON, Osage City, Kan.

I presume this sweet-clover pamphlet may be had by applying to the Kansas State Board of Agriculture, Topeka, calling for circular 44.

FETERITA IN KANSAS.

This same bulletin contains 28 pages devoted to feterita. The matter is well illustrated with beautiful engravings showing both sweet clover and feterita, and these are very valuable documents. The statement in regard to feterita emphasizes

the fact that it will grow during a dry spell and produce a crop when corn and almost everything else was a failure. I am surprised, however, that nothing is said about it as a substitute for wheat in making bread, cakes, etc. Our own feterita here in Medina has been slowly maturing because of the cool weather and almost incessant rains all summer long. As I write, Sept. 30, just a few of the heads have sufficiently matured so that it will be just right to cook as a breakfast food; and I for one consider it a most delicious dish. The seed is very easily separated from the heads, and, in fact, it will drop off if it is not harvested at just about the right time; and I cannot imagine a much shorter cut from producer to consumer. Just lay the heads in the sun for a day or two, thrash out the grain, and boil it as you would boil rice or oatmeal. Put on some honey, and butter and cream; and if you do not like feterita I shall be surprised.

SWEET CLOVER NO LONGER A DESPISED WEED.

It has been toward forty years since I began to declare that sweet clover is *not* a weed, and that *no* clover should ever be classed with noxious weeds. Those of you who have read GLEANINGS for forty years know what a storm of abuse I have been receiving for the stand I have taken, up to the last three or four years. I have just looked back through the old numbers of GLEANINGS, and I find there letters from beekeepers who were feeding sweet clover to cows and other stock, and the stock ate it in preference to anything else, and did better on it. With such testimony as that, coming more or less for *forty years*, every little while somebody was stubborn and contrary, and declared it would be the ruination of farmers, like Canada thistles, if it once got a start. This whole matter was brought to mind just now by the receipt of a pamphlet of about 25 pages, sent out by the I. H. C. Agricultural Extension Department, Harvester Building, Chicago. It is sent to any address for 4 cts., or for 3 cts. each in quantities. I will give you just a glimpse of where sweet clover now stands by quoting one letter from the pamphlet mentioned:

THREE THOUSAND ACRES OF SWEET CLOVER; GARDEN CITY BANKER GIVES SOME REASONS WHY HE BELIEVES IN IT.

About eight years ago I started to feed this sweet clover, the white-blooming (*Melilotus alba*) variety, which is considered the best; and from watching my stock feeding on it I began to believe that they did better on sweet-clover hay than almost any other roughness, so I commenced to spread the fields and got to sowing it until now I have about 3000 acres—this, too, on good alfalfa land when clover seed is high and alfalfa seed is cheap; consequently I must

deem it of some value as compared to alfalfa, and also must have some reasons for sowing sweet clover. Here are my reasons:

Sweet clover has proven to be as good feed for all kinds of stock as alfalfa.

It makes a better early pasture, will not bloat stock, and is easier grown.

It grows without much preparation of the ground, will grow on ground too poor for any other crop, and is about the best fertilizer for worn-out soil of any of the clovers.

Last year, from 120 acres of ground I got a little over 900 bushels of seed, which sold for \$10 to \$15 per bushel.

Last year I sold a carload to one seed-house—the first carload lot known to have been sold by any one grower of sweet clover.

This year I harvested about 600 bushels off 200 acres, and it is selling at \$15 per bushel for the hulled, re-cleaned seed.

I attribute the reason for sweet-clover seed being so high and alfalfa seed so cheap to be because alfalfa will grow in only a few states profitably, while sweet clover will grow in nearly every state in the Union, if not in every one.

It produces the best blossom for bees of any of the clovers.

It is a help to orchards, keeping down weeds, making hay as well as fertilizing the land.

I cut my first crop for hay the latter part of May. The last of August the seed is ripe, then another short hay crop. You can allow the first crop to go for seed, but the stems get pretty thick and full, so that it is harder to handle. It is a biennial legume plant, so that the first year it does not go to seed, but will seed the next year. Enough seed falls off every fall to reseed the ground so that it is a continuous crop similar to alfalfa.

I thrash with a regular grain-separator, either out of the stack or shocks.

I think 10 lbs. of seed per acre is sufficient to sow in this section.

I prefer to sow in the fall and winter. The seed is of a hard nature, and seems to like some freezing weather. A good many have excellent success by sowing in February, March, April, May, and June.

I think a good deal depends on the season; in fact, almost all.

Prepare land about as for alfalfa. I have had good success, however, by sowing right on the sod and then harrowing or disking.

The yield is about the same as alfalfa, but it makes a larger tonnage than alfalfa under similar conditions.

It seems to stand all kinds of pasturing, both in the spring and fall.

I know of some fields that are pastured clear up into May, and then make a good crop of seed and a hay crop besides.

I do not think it lasts as long as alfalfa for pasture in the fall.

There is no bad effect on the milk of cows pasturing sweet clover or eating the hay. I refer to the white-blooming variety.

I am absolutely positive about its not bloating any kind of stock, and it will not give horses the heaves as alfalfa sometimes will.

A good crop of seed averages from about 4 to 15 bushels per acre. I have had it yield as much as 15 bushels per acre.

I consider it equal to alfalfa as a feed; that is the reason I am growing it in preference to alfalfa—one of the reasons, at least.

SWEET CLOVER SEED—GETTING THE HULLS OFF.

Could you tell me how to hull a small quantity of white-sweet-clover seed for experimental purposes? Can it be done without a special machine?

Conneaut, O., Aug. 15. D. B. PHILLIPS.

My good friend, I am sorry to say I know of no way to get off the hulls of sweet-clover seed without a special machine. Just now I am gathering seed from that special plant described in GLEANINGS, and I thought may be it would germinate better if I could get the hulls off; but as the seed was not yet dry, it seemed next to impossible, so I planted it with the hulls on, and I am glad to tell you it was up nicely in five days from the day of planting. I think seed taken direct from the plant before it is dried out will germinate quicker than the usual dry seed with the hulls on.

DRAINAGE, BOTH NORTH AND SOUTH—THE IMPORTANCE OF IT.

With the light sandy soil we have down in Florida, as a rule, one might think that drainage is of less importance than here in Ohio on our clay land; but the fact is, no first-class results are secured in Florida—at least in Manatee Co., without good thorough drainage. My neighbor Rood has put in hundreds of dollars' worth of tiles; and our experiments in tiling have shown such good results that where I have not got in tiles I have raised up the beds of soil perhaps a foot or more above the paths that carry off the water during our great rains. The question has often come up as to whether it will pay to put in tiles, and, furthermore, how deep to put them, how far apart, etc. The clipping below, from the Jacksonville *Times-Union*, answers it more directly than anything I have before come across:

DRAINAGE FIRST.

"My land is low, wet, and sour. What kind of lime should I get to sweeten it, and how much will be necessary?"

Answer.—Before applying any lime, establish good drainage. This means that the standing water in a hole dug the day before will not come nearer than 2½ feet to the surface of the soil, and we would much prefer to have the distance at least three feet. There is no surety in cultivating land with good results, whatever you may do in the way of liming, fertilizing, and tilling, unless you have good drainage. After you have made your water conditions right, apply about three tons per acre of ground limestone, which should be bought in car lots, minimum fifteen tons.

Dig a hole or several holes in your garden some time when it does not rain, and then come around and see if water is standing nearer the surface than 2½ feet. I suppose 2 feet would do pretty well, but no doubt 2½ feet or 3 feet would be better. Keeping watch on how high the water stands in the holes you have dug will aid you in deciding how deep and how far apart to put the tiles. If the work is well and properly done, you will have something that will pay you good interest year in and year out for the rest of your lifetime.

POTATOES AND POTATO-GROWING HERE IN THE NORTH.

About the first thing I did after I got back to Ohio last May was to plant some potatoes. I sent and got half a bushel of Early Ohio and a peck of Six Weeks. The latter are said to be a little earlier than the Early Ohio. I think both were planted about May 15; and as the weather was favorable both made a good growth. Now, our Medina garden has grown potatoes for a dozen years or more, and potatoes have been on the same ground year after year. The consequence is, they usually scab badly. There are grubs and worms also that seem to bite into them. It illustrates the folly of trying to grow the same crop year after year on the same ground. Mrs. Root finally declared that she did not want any more potatoes planted in that old garden. Well, the Six Weeks grew rather better than the Early Ohio, and they ripened up quicker. From the peck, I got about three bushels of nice potatoes of good quality, with very little scab. I have just now planned to ship them down to Florida to try them there. The half-bushel of Early Ohio gave also about a barrel, but was later in ripening, and therefore caught the blight, and were also fearfully scabby, and gnawed up by worms and grubs. Besides that, they were badly rotted, and kept on rotting after they were dug and put into a cold cellar.

It has been said that the Early Ohio has been grown for so many years that it is "worn out;" but because of its excellent quality a good many still hold on to it. Well, now, there is a good deal in getting the right variety of potatoes or a potato suited to your soil. A little later I planted a few Idaho Russets. These were not scabbed at all, but the blight stuck the vines before they were quite mature. I also planted a few Carman No. 3. These gave a nice crop of smooth potatoes with just a little rot; and my son-in-law, whose garden adjoins mine, had a dozen bushels or more of very nice smooth Carmans. But potatoes have not been grown on his ground as long as on mine. By the way, when you discover your potatoes are beginning to rot, especially if the season is wet like the one just past, the sooner you get them out of the ground and get them thoroughly dried out, the better. Of course they should be dried out in a cool dark place, for sunlight injures potatoes for table use, as any good housewife can tell you.

The complaint has been made that the general run of farm papers give only good reports—successes and *not* marked failures

—so I think I will give you a report of one of my failures.

About the first of June I saw a potato highly recommended in one of the catalogs. It was called the Commercial. One potato would be sent by mail for 15 cents. I accordingly sent for one; and as it was of good size I cut it so as to get 17 eyes. The weather was favorable, and they made a most astonishing growth. I gave each plant extra care, and each vine grew so it could be raised so as to reach as high as my head; and some of them were almost as large as a hoe-handle. I expected an enormous yield, and was planning to tell the readers of GLEANINGS how I got a *barrel of potatoes* from only one potato planted. Well, after the vines died down (I think they were cut short by blight) I proceeded to dig them. How many potatoes do you suppose I got from my 17 hills? Not enough to fill a quart basket—quite a difference between a quart and a *barrel*! I noticed that the ground was flat and not being heaved up as we generally see it where there are great growths in the potato-vines. I saw a *few* evidences of small potatoes that had rotted, but nothing to mention. In some hills where there was this great growth of vines there was *not a potato at all*. Now, it may be that this Commercial potato is very late and needs a long season to mature; and possibly the blight struck it before it had had a chance to set and grow tubers. It also illustrates the fact that certain varieties are adapted to certain soils or localities. I presume I have tested a hundred or more varieties of potatoes that have been highly recommended; but only a few seemed to be adapted to our Medina clay soil. Of course I might have warded off the blight by proper spraying; but we have so few potatoes here that I did not think it worth while; and I am inclined to think the unusual wetness had much to do with the prevailing blight in this region. In fact, there were times when the vines and foliage did not get sunshine enough to dry them out, for many days in succession. In our Florida home, pretty much all the varieties I have tested gave a fairly good yield.

REDBUGS, SO CALLED; ALSO SOMETHING ABOUT MULCHING POTATOES WITH PINE NEEDLES.

I have a patch of dewberries in my garden which are heavily mulched every spring with manure and straw (pine leaves). Last spring, before putting on the mulch, I took some potatoes about an inch in diameter, and planted them whole, down the middle of the rows, barely covering them. Then the mulch was put on and nothing else whatever done to them until digging time. The result was four bushels of potatoes, fine ones, from about ninety hills. Neither

bugs nor blight troubled them, and the vines remained green at least a month after those planted in the ordinary way and sprayed were dead.

I have just seen your note in GLEANINGS for Feb. 15, about the Florida redbug. Some fifteen or twenty years ago I saw published in some paper a preventive which has since given me untold benefit, and which has been worth many dollars to me, as I am very sensitive to redbug bites. Such bites will give me more trouble than forty beeings. I have been getting them ever since I can remember (when not using a preventive), and haven't become insensible to them yet. Take fresh oil of cloves (that which has turned dark with age is little good), and rub a few drops on the ankles every morning before putting on socks or before going where you are liable to get redbugs. I have gone into blackberry-patches, among old logs, etc., where redbugs are thickest, and not received any at all, or very few, while if I omit the oil of cloves I get dozens of them on me. When picking berries, it is well to put a little around the waist, on arms, etc. This is not quite as efficacious for women as for men, as their skirts catch them, I suppose.

May God bless you, and spare you many years to prove my remedy and to continue your fight for the right.

A saturated solution of kerosene oil and gum camphor is good after the bug gets on, and is picked out with a sharp-pointed knife.

Arcola, N. C., Feb. 25.

J. F. HUNTER.

My good friend, I fear from your concluding sentence that what you call redbugs in your locality are different things from the Florida redbugs. There are three insects that worry humanity down in Florida—first, the sticktight flea. This bothers the poultry by getting on their combs and wattles—especially the Leghorns and Spanish, which have large combs. These sticktight fleas are well described by their name, and you can pick them out with a pair of tweezers after they start to burrow in the chickens or on your ankles. The redbug, however, is almost microscopic—in fact, I have never been able to see one. They trouble us more or less every season without fail, while the sticktight fleas have not appeared on our premises for the last two winters. They live principally in dry sand, under buildings and such places. When there are abundant rains they are seldom found.

The third insect, I believe, troubles me most of all. It is the well-known common chicken mite. To make sure I was not mistaken I sent a sample to Washington. I do not remember that we ever had any on our premises until I bought a pair of guinea fowls of a party in Pennsylvania. I sent for them with the understanding that they would keep away hawks; but they did nothing of the kind, for they rambled all over our five acres, and might be up in the tops of the highest trees while the hawks were making a swoop for the chickens on the ground. The first season that we got guineas I found a sitting hen literally covered with mites—at least the nest-box was

swarming with mites. We burned up the straw that was in the nest and put the box on top of the fire until it was charred inside and out; then soaked it with moth-balls dissolved in kerosene; and this latter remedy is cheaper and more effective, according to my experience, than any of the much-advertised chicken-mite remedies.

Our worst trouble is with sitting hens. If you are not very careful you will find mites crawling on the eggs from the sitting hens. A galvanized-iron nest-box has been recommended; and I am inclined to think it would be a good thing. When I sent a sample of the mites to Washington they said it was quite unusual for the mites to be found on human beings. They do not seem to trouble Mrs. Root; but they get under my arms and under my knees—sometimes in my hair, and not only annoy me by their crawling about, but they sometimes bite excruciatingly. I hope it is true that only on rare occasions will they pester and annoy persons as they do myself.

In regard to mulching potatoes with pine needles I have often wondered whether pine needles were good for anything. I can readily understand that the strong odor from these turpentine pine needles should repel bugs, and they may also possibly repel blight, as you suggest in your letter. I expect to try it soon.

"LOOK OUT FOR PICKPOCKETS."

The following, clipped from the *American Poultry Journal*, illustrates a plan that is getting to be too much the fashion of late in the way of picking the pockets of good honest hard-working people:

Charged with using the United States mails to defraud, G. A. Davenport, aged 34, of Brookville, N. J., has been arrested at Apollo, Pa. According to Postoffice Inspector J. D. Wardle, of Trenton, N. J., Davenport operated under the name of the Cedar Ridge Poultry Company at Brookville, and advertised in the daily papers to sell baby chicks at seven cents each. Instead of filling the orders he received with the cash, he disappeared. Later he was located at Apollo, Pa., where he was operating under the name of the Kiski Poultry Farm. His Uncle Samuel will now take care of him.

I have given place to the above, principally to ask our friends if they know of anybody in the bee business who has been doing similar work in, say, advertising queens at a low price. If so, give us the information and we will give him free advertising. And this illustrates what I have mentioned before—be careful about sending money in answer to any advertisement that does not have some name signed to it in black and white instead of some high-sounding title like "Poultry Farm" or "Bee Farm," etc.

A GLIMPSE OF THE PICTORIAL REVIEW FOR 1916.

Pictorial Review has made a reputation for its worth-while fact articles, and special attention will be paid to this part of the magazine in 1916. Mabel Potter Dagget is at work on a series of articles entitled, "Phases of Feminine Unrest." There will be a series of articles by Anna Steese Richardson, author of "Better Babies and Their Care," on "A Nation-wide Clean-up Campaign."

Among other writers of special merit whose best work will appear in Pictorial Review in coming months are Dr. Orison Swett Marden; Helen Louise Johnson, Chairman of the Home Economics Department of General Federation of Women's Clubs; Dr. Frank Crane, and others.

STORIES.—With Pictorial Review you actually get four great \$1.50 novels worth \$6.00, which will appear in serial form in Pictorial Review during 1916. These four complete book-length novels from four of the most popular living authors will sell for \$1.50 each after they have appeared in Pictorial Review.

FASHION INFORMATION.—Pictorial Review is today recognized as one of the most reliable "fashion authorities" in over one million of the best American Homes. If you wish to see the newest, chic styles every month, you need PICTORIAL REVIEW.

The A. I. Root Company, Medina, Ohio

Gleanings in Bee Culture

Published by The A. I. Root Co., Medina, Ohio

VOL. XLIII.

DECEMBER 1, 1915

NO. 23

EDITORIALS

A REPORT of the Ohio State Beekeepers' convention will appear in our next issue.

THE double telescope covers do not blow off in a high wind like the single-board covers. We have had ample evidence of this at several of our outyards of late.

The Cover Picture—A Porto Rican Apiary

JUST as all landsmen love the sea, whether they have ever stood upon the shore or not, so every inhabitant of the temperate zone sometimes feels the call of the tropics. The land of palm and pepper has a strong fascination for us all whose homes are half-way up toward the pole.

The waving cocoanut of the cover picture stands sentinel over an apiary of some forty colonies, the property of Haydn Randall, of Garrochales, P. R. The low trees in the foreground are grapefruit, the remnant of an abandoned grove. Just back of them are almond trees.

Mr. Randall has built up his apiary of twenty colonies brought to the spot about a year before the picture was taken. The section is not an excellent one as bee pasture, since most of the land is devoted to the culture of sugar cane.

Dadant & Sons

In our issue for Oct. 15, page 850, after giving a general writup of the general field meet at the home of the Dadant & Sons, Hamilton, Ill., we promised later to introduce the members of that firm to our readers. We now have pleasure in doing this. See page 996 this issue.

Mr. L. G. Saugier is a son-in-law, who, together with the sons, makes up the personnel of Dadant & Sons. They all appear to be men who are willing to take off their

coats and work whenever necessary. As we have already explained, each has a department of his own, and the Dadant business, presided over by the father, C. P. Dadant, runs just like clockwork.

While they are direct competitors of the A. I. Root Co., they afford the kind of competition that boosts, not their own business alone, but others also. They are most emphatically not the kind of competitors who are jealous of another's success. That they have made a success of their business is shown by the general air of prosperity about the plant and about their homes.

Theirs is the kind of organization that is destined to continue, because it is bound by blood ties—the strongest kind of ties this world knows.

Is there a Disposition to "knock" Extra Yellow Bees?

WE have been accused by one of our advertisers of unfairly "knocking" yellow bees; and perhaps he would almost think that our correspondent, Mr. J. L. Byer, in his department, page 971, this issue, and the editor were working in collusion. The fact is, we did not know before his opinion on the subject. We have contended that not *all* yellow bees are inferior; but so many had proven such that we thought we were only doing our readers a real service by entering a word of caution. Some breeders of these bees breed, first, for honey production; second, for wintering qualities; third, for color. When extra-yellow color is secured with the other necessary qualifications, there is no objection, of course, to the bright yellow. Other things being equal, they should have the preference. But in some instances, at least, color seems to have been the only desideratum. Too many yellow bees have been first to die during winter, and too many of them have been cross—very cross; hence we have felt

it to be our duty to say to those who breed extra-yellow bees that these undesirable qualities should be eliminated. This does not mean that some have not done it.

The greatest complaint, however, against some of those who have bred extra-yellow bees was because they advertised five-banded stock, and furnish only the three and four banded. The terms "five banded" and "yellow all over" have been eliminated from our advertising columns, and now the term "golden" or "extra golden" has been substituted. This is better.

Not too much Packing, but too much Snow

IN our issue for November 1, page 905, Mr. A. J. Knox has an article on the subject of quadruple winter cases. Referring to this, one of our correspondents, under the non de plume of H. I. Bernation, thinks Mr. Knox must be mistaken. He writes:

The data in the article by A. J. Knox, November 1, pp. 905, 906, do not seem to be such as to warrant all of his conclusions. He says that the first year he leaned covers over the entrances, and when the bees were found dead outside he blames their death on too much packing. Now he omits these covers and gives less (insufficient) packing and gets better results. He deprecates bottom packing, but commends snow for that purpose. With a 40-mile breeze the scant (twelve bushels to the case) packing would probably be no better than single-walled hives were it not for the providentially provided snow. It would be interesting to learn how Mr. Knox found out that his bees got too warm when completely covered with snow, and why upward ventilation is needed in thoroughly packed hives. The loss of four per cent seems to be smaller than usual. Is this good wintering? Should not Mr. Knox try packing his bees thoroughly and see what happens? His creosote stain sounds good, but it is not clear why he prefers thin lumber unless it is on the ground of expense.

H. I. BERNATION.

Mr. H. I. B. is correct. Too much packing under and around each hive certainly can do no harm, and it may do a great deal of good. Putting a board in front of the entrance of a colony during winter as he did to shut out the cold wind looks very fine in theory, but it nearly always proves disastrous. The bees apparently become confused, lose track of their entrances, and die outside around the hives in thousands. We tried out that scheme years ago, at one of our outyards, and found it to be a failure. Mr. G. M. Doolittle, at the time, noticing that we were giving this thing a pretty thorough test, warned us of the results, and we got them all right, in that we had the biggest loss at that yard we ever had. Mr. Knox should not, therefore, attribute the loss of bees of one winter to *too much packing*, but rather to too much snow and to the boards in front of the entrances. Screen-

ing the wind from the entrances by a slanting board or cover is one of those pretty things in theory that do not work out well in practice. When hives are "completely covered with snow for several months" it is enough to kill any bees. If the entrance is closed with snow or ice the hive, whether packed or not, will develop too much heat, and, of course, the bees will soon die.

"Slightly Exaggerated" again; Pulling Stings in Lots of 10,000 to Cure Rheumatism

WE recently gave an address on bees, accompanied with a live-bee demonstration, before a Rotary Club in one of our big cities. These clubs are made up of live business men whose aim is to push business. At every session they call on an outside man to give an address, generally along his own line of work. It was on one of these occasions that we gave a talk on bees that we happened to mention incidentally that there was much ado in the newspapers about the wonderful properties of bee stings for the cure of rheumatism; and while we added that stings might be valuable in some kinds of rheumatism, we believed that, in most cases, the results were only negative. We also stated that the homeopathic school of medicine used bee stings in making up a medicine known as "Apis Mellifica;" that we had years ago filled two or three orders for ten thousand stings; but distinctly stated that we were not accepting such orders now. We did not offer any opinion as to the value of these stings in curing diseases.

We have learned by experience that it is best to be cautious in the presence of newspaper men, and so we were on the occasion mentioned; but imagine our astonishment on seeing in several papers for a week or so back some statement to the effect that the A. I. Root Co. was pulling stings in lots of 10,000 from bees, and then sending them out broadcast over the country to cure rheumatism! Wow!!! The story has appeared in so many forms, and so awfully exaggerated, we are wondering what our subscribers think we did say. As it was, we have got considerable free advertising. All we can say to one and all is that we have no bee stings for sale, either to the homeopathic schools of pharmacy nor to the thousands of sufferers all over who have rheumatism. When bee stings do "cure" it is our honest belief it is the outdoor air coupled with enthusiasm and exercise that does the business. A good garden and a good hoe will do the same.

Distance Bees Fly in Quest of Stores

WE desire to indorse what our correspondent, F. M. Baldwin, has to say on this subject in this issue, page 987. We have traveled quite extensively over this country; and while we have found occasional locations where bees would fly five miles and sometimes even further, we are satisfied that they seldom go over $1\frac{1}{2}$ miles, and usually not over a mile. A great many times our own bees at our outyards seem to go less than three-quarters of a mile; and yet many years ago we found our Italians, that we were just introducing, more than three miles from home. There were no other Italians in the locality, and so we knew they were our own bees. That they do this generally in this locality is not true.

It has been stated that bees have long-range vision. When the country is somewhat mountainous or hilly they are known to fly from one hill to another, the distance aggregating five miles. Similarly they will go across a body of water; but on ordinary level wooded country they will fly scarcely over three-fourths of a mile. It is our opinion that they seldom go more than three-fourths of a mile. Our bees, at one yard, at least, seem disinclined to fly over a piece of woods half a mile away. They will go up to it and into it, but will not fly over it.

The localities in and about Medina will not support, either for comb or extracted honey, much more than about 35 colonies in a place; but there are places that will support anywhere from 200 to 500 in one location. The late E. W. Alexander's location at Delanson, N. Y., was a case in point. From that apiary site buckwheat fields could be plainly seen three and five miles away. When this is the case the bees have an opportunity to see a long distance. If on an elevation they will fly far across a valley. If on a plain, as in the West, if no shrubbery or wooded country is in the way, they will go sometimes two or three miles, and sometimes even five. We have cases of this in some of the alfalfa country.

The conditions in and about Bradentown, Fla., are not such as to favor long-distance flights. The country in the wild state is covered with pines, swamp lands, and hammock land, and in the cultivated state with citrus groves. There is almost no territory about Bradentown that is free from growth of some kind, and that is the reason why the range of flight is so short.

If our theory is correct, that the flight of bees in quest of nectar is dependent on the distance they can see pasturage, it will help

us to determine the distance and location of our outyards, and the size and location of apiaries will make all the difference between success and failure. The question is a good one to discuss during the winter months, in order that we may arrive at some definite conclusion by next spring.

A \$30,000 Damage Suit against a Silver-smelting Company for Alleged Damages to the Beekeeping Interests in the Vicinity

FOR some time back there have been rumors to the effect that a silver-smelting concern in Canada was causing widespread damage to the beekeepers in the locality. Attorneys from both sides have approached us, asking for information concerning other cases of this kind. The only one to which we have been able to refer is the one recorded on page 616 of our May 1st issue for 1907. At that time it appears that the smelter people settled with the beekeepers in the sum of \$60,000. The case was long drawn out, and after a long and severe struggle the smelters in the Salt Lake Valley, Utah, settled on the basis above mentioned.

It was stated at the time that prior to the advent of the smelters the Salt Lake Valley was the banner bee country of the state; that there had been kept up to that time as many as ten thousand colonies of bees. At the time the statement was made, it was alleged that less than ten colonies were left. One beekeeper lost a thousand colonies. It appears that each of the smelting companies paid \$15,000 each, or \$60,000 in all, which amount was probably distributed among the beekeepers claiming damage.

In several trips we have made in various parts of the western country, we heard complaints of the destructive action of the smelter gases on bees and vegetation. It has been said also that the gases not only kill the bees but destroy the plants that furnish the nectar supply.

Within the last few years we have heard nothing about any further complaints except the one originating in Ontario, Canada. How the beekeepers of Salt Lake Valley came out at the time we do not know. We certainly have subscribers in the Valley now, and are under the impression that the smelters are still operating. Whether that settlement of \$60,000 was a settlement for all time we do not know.

Some time last year we wrote to Lewis Minor, one of the foremost beekeepers of Ontario, Canada, for particulars concern-

ing the suit against the smelting company. He writes as follows:

A movement was started in preparing this action by the beekeepers in 1912 against the silver-smelter which goes under the name of the Coniagas Reduction Co.; but the writ was not issued until June of this year. We expect it to be brought before the courts in November. Following are the names of the beekeepers bringing this action:

John Newhouse, Mansford Niles, Peter Warner, Henry Ackrigg, Wm. Selby, Mrs. Adelbert Clark, John R. Secord, Robt. T. Miller, Wm. Craft, Edward Willix. There were several others who claim loss, but did not go in with those trying to recover damages. All the bees were lost within 4½ miles of the plant—about 700 colonies—as soon as they began operating six years ago. The beekeepers interested in this suit are claiming \$30,000 for loss of their bees, appliances, and honey crops for six years. I understand there are many smelters in the northwestern and eastern states that did considerable damage to the livestock industry, and also killed bees.

I am acting as agent for the beekeepers; and if any one can give any information, please send it to me. This case will, no doubt, establish a precedent for others losing bees in this way.

Smithville, Ont., Sept. 4. LEWIS MINOR.

The attorneys representing the beekeepers are Bradford & Bradford, of Dunnville, Ontario. Any beekeepers in the West or elsewhere who can give any information would do well to consult the attorneys prosecuting the case. We will keep our subscribers advised of any further developments.

=====

The Embryology of the Honey Bee—A Review

BEEKEEPERS know that about three days after the egg is laid by the queen there hatches from it a small, white, worm-like larva. Where this larva comes from, how it was formed, and why it is as it is, are questions that perhaps have never occurred to many beekeepers. It may be asked, "What difference does it make to the practical beekeeper?" This question is hard to answer if a dollar-and-cent reply is expected; but if our interest in the honeybee is limited by the financial boundaries, then beekeeping becomes dull drudgery, and the fun of the thing is gone. A good beekeeper is a broader man than that. His interest is immediately aroused when a new investigation of the bee is announced, and he wants to know about it.

Dr. James Allen Nelson's book, "The Embryology of the Honeybee," is doubtless the most thorough discussion of the development of any insect yet published. It is the only publication in English to which we may go for information as to what happens in the bee's egg. The reader who is unfamiliar with such work will not follow all that is in the book; and even the person who has had some technical training may

have a little trouble in places. We must have something to put into a book before we can get everything out, and this is as true of a practical book as it is of a scientific one. However, every intelligent reader of this work will rise from a perusal of the book with a consciousness of a little less mystery about the development within the egg, and that is worth while. The book furthermore continues to give information when studied.

Each system of organs is traced from its earliest discernible stage to the form which it has in the young larva; in fact, the development is carried from the egg immediately following fertilization to the well-organized larva. To the student who desires information concerning the development of the honeybee as compared with that of other insects, full information is included. A comprehensive bibliography is included. The illustrations, all but two of which were drawn by the author, are remarkably clear in the reproductions.

Dr. Nelson is entitled to our thanks for giving one more important stone to the foundation of beekeeping. It may seem a long way from his contribution to apary practice; but the foundation of beekeeping can be learned only by scientific investigation, and an extended contribution such as this makes the superstructure all the firmer.

The book is issued from the Princeton University Press. It was too large to be included in the publications of the Department of Agriculture, and beekeepers are indebted to the Princeton Press for providing a permanent record for this investigation. The presswork is excellent. The management realizes that this work will not be one of the season's "best sellers," and their primary object in accepting it was not financial gain. Beekeepers who want everything published on bees, and who are curious about the things of the hive, will want to peruse the book.

James Allen Nelson, *The Embryology of the Honeybee*. Princeton University Press, 1915, 288 pages and 6 plates. Price \$2.00. If more convenient, this work may be ordered from GLEANINGS at the same price.

=====

A Correction

MR. F. R. BUCHANAN, of Glendale, Cal., the man who so kindly carried us in his machine up into the skies (see pages 875 and 943) begs leave to make a correction. We stated that he had about forty colonies. As a matter of fact, he has about 200 more in another yard, which fact we now recall, with apologies to Mr. Buchanan.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

At present there's a very carpet of white clover, although there's no telling what the winter may do to it. [It is the same everywhere we have been.—Ed.]

If you find more than one egg in a queen-cell it's a safe guess that laying workers are present. But there are exceptions. June 30 I found in No. 38, which had a laying queen, several cells containing 2 eggs each, and one with 4 eggs. July 26 much the same thing was repeated.

YEARS ago, when I was chorister in Moody's church, Chicago, a visitor sat beside me on the platform in Sunday-school, and quietly told me his business was trying to keep bad things out of the mail. I little thought then that he would do such a great lifework, for he was none other than Anthony Comstock.

A. I. ROOT, what you say about the liquor-traffic and counterfeiters, p. 18, ad. pages, set me to thinking. Suppose a community where counterfeiters abound should ask that a vote should be taken whether counterfeiting should be made legal. You'd scout the idea. Yet here in Marengo, where there are no saloons, the law allows a vote to be taken that may bring in saloons.

"WHO invented the quadruple winter-case?" p. 875. Looks like it might have been invented by more than one, each ignorant of what was done by others. About 30 years ago I saw these cases at Dundee, Ill., at Jesse Oatman's. Some were one-story, for four hives, and some two-story for eight. I have an idea that Oatman invented them, as well as others. [Now who can go Oatman one better?—Ed.]

PHILLIPS and Demuth, as quoted p. 878, say, "The ideal toward which the beekeeper should work is to keep his colonies during cold weather absolutely protected from wind." That explains why bees may be wintered outdoors in a still situation 200 miles north of here better than here, where the winds are severe and long continued. [Winter packing is not as important as seclusion from wind. Both are necessary, however.—Ed.]

SOMEWHERE about 9 o'clock each weekday morning is a time of special interest, when the daily paper comes. This is Nov. 1, and I can hardly wait for the paper day after tomorrow, for then I'll probably know whether you've downed the saloon in Ohio

or the saloon has lowned you—for a while. [We didn't do it; but there is gloom in the liquor camp. They know we have made such big gains that we are sure to win in 1917 if not in 1916. We are going to keep up the fight; and if we make as much gain this year as we did last, we shall make Ohio dry in 1916.—Ed.]

MR. EDITOR, you think, p. 879, that a queen just received by mail will be better accepted if her cage be put in center of brood-nest than if stuck in entrance. I wish we might know how that is. I use entrance because easier, but I've had a notion that a queen is more readily accepted there because she has a better chance to become acquainted with the fielders, and the fielders are the ones that raise a racket with a new queen. And I should expect it to work the same with a queen out of the mail as with another. [Possibly you are right. We should like to hear from others.—Ed.]

G. M. DOOLITTLE, in addition to the good reasons you give for using full sheets of foundation in sections, p. 886, there's a very important reason that you do not give, although Allen Latham alludes to it, p. 888. If there were no other reason for full sheets, I would use them for the sake of keeping the queen from laying in sections. With starters the bees will build drone-comb, and then if drone-comb is scarce in the brood-chamber the queen is sure to go up unless an excluder prevents. Even with an excluder the bees will sometimes hold the drone-cells open for the queen. [This is a point that has not been sufficiently emphasized. We know it is true from many reports received.—Ed.]

THAT case of chilled brood, p. 833. Dr. Phillips leans to the view that in the fall, at close of brood-rearing, bees not only cease to care for eggs the queen lays, but drag out brood that has been reared. Possibly that may account for the supposed chilled brood, and possibly chilling may account for the brood that Dr. Phillips thinks the bees ruthlessly destroy. I rather lean to Editor Root's view, but I've seen things that favor the other view. I wish we knew. [In the case referred to, the dead brood was found only in front of the colonies weakened by foul brood, and in those colonies on which upper stories of wet combs had been placed for the bees to clean up. In this case the colony was made relatively small for the size of the hive.—Ed.]

Grace Allen

THE DIXIE BEE

Nashville, Tenn.

A favorite question for discussion seems to be, "Do bees dislike black?" Well, just ask Uncle Milton, the old darkey who helped me one day recently. And then you might ask him how well blacks like bees.

Here is winter almost at hand, the long quiet evenings bringing their great opportunity for reading and study—an opportunity of measureless value to beginners, and seldom neglected by more experienced beemen who have found success lying always along the path of progress.

I am practically convinced that the dead brood I mentioned last month was chilled by that one sudden cold spell. A day or two after I discovered it I tried to show it to Mr. Allen; but the bees had cleaned up so thoroughly that there was little evidence left.

I believe I like Mr. Auten's watering-device, p. 583, July 15, the best yet, if it just won't prove a breeding-place for mosquitoes. It seems as though there would be scarcely enough movement of the water to prevent the wet sand and the grass, at the spot where the constant drip comes out, from being an ideal breeding-place for these pests. I should like to know how that has worked out in experience, for otherwise it looks like one of the simplest and most satisfactory plans of all.

Since mid-September our brood-chambers have been decidedly yellow, the top-bars of the frames showing a yellowish tinge, the cappings being a bright yellow. Does goldenrod produce that effect—assuming that they work it? I have never seen it so pronounced before. [Yes, we have seen comb honey produced from goldenrod that was yellow all over—honey, cappings, and section. In GLEANINGS for April, 1909, we showed a picture of some goldenrod

honey that was very yellow, in contrast with ordinary comb honey.—Ed.]

Though by this time the weather is gray and chill, that threatened early fall did not materialize, October and early November staunchly upholding all the traditions of golden autumn-time. "Fooled again," if I may quote Dr. Miller. And by the way, Dr. Miller, all of us will concede most heartily the inspiring possibilities of a beekeepers' meeting of three when that three happens to be the government entomologist, the editor of GLEANINGS, and the Sage of Marengo himself.

On page 491 Mr. Holtermann advises beginners to study the correct method of handling frames, and then to do it right. That may seem a little thing, but little things are very important. Tradition says that Michael Angelo answered a friend's protest over his painstaking attention to details, with the succinct remark, "Trifles make perfection, and perfection is no trifle." If big factories can pay out thousands of dollars to experts to install system and scientific management in their plants, to the profit of both owners and

DEATH

So many things I do not understand!
My neighbor's house today is strangely still,
Insufferably sweet with heaped-up flowers.
Friends enter softly, greeting hand to hand;
A silence never-ending seems to fill
With shadowed hush the long, reluctant hours.

(Though once across the aching air so tense,
Insistent in his love and ignorance,
A baby broke the breaking hearts again
With quivered "When she tummin back? Oh when?")

Beneath a cloud-veiled sky and shaken trees
My slow steps brought me home, and all around
The withered leaves lay dead on every hand.
I stood at last among my quiet bees,
Stood there and stood, nor made the slightest sound—
So many things I do not understand!

workmen, mightn't it be worth while for amateur beekeepers to pay out a little thought and attention to study the best ways to do things, and then a little persistence till the best ways become habits?

But I can not sit on that wiggly hive-cover! Not happily. It tires me immeasurably more to balance the unsteady cover than to kneel by the hive, which seems to be my favorite apiarian attitude.

An interesting letter from Mr. Bruce Anderson, Forsyth County, Agent in the Farmers' Co-operative Demonstration work of North Carolina, reports that the first year's work of the bee-club started in that locality last spring has been very encouraging, with a promising outlook for next year.

Mr. E. G. Carr, bee specialist from Washington, is working in North Carolina at present, and they are planning to hold several demonstrations with his assistance. This year's crop was almost a failure in that state, the average per colony very low, and the quality nothing to boast of. But the beekeepers' ever-saving "next year" looms big with promise, with indications of plenty of white and crimson clover.

Mr. Anderson in his letter backed up Dr. Phillips' statements, page 853, Oct. 15, about the general need of the South by remarking that the industry among farmers in his state is very backward—"the box hive is generally used, with the idea that bees ceased to be profitable many years ago." He adds that instruction is the one thing most needed.

In this connection I want to mention Dr. J. S. Ward's work in Tennessee. Dr. Phillips says it is the duty of a bee-inspector not only to treat bee-diseases but also to give instruction. That is what Dr. Ward is doing in Tennessee. During the summer of 1914, in addition to lectures (and regular inspection work), he accompanied the state agricultural train in its tour of the state, carrying samples of up-to-date supplies, explaining their use, and constantly by talk and printed literature spreading the gospel of modern apiculture.

We are all deeply interested in the matter of wintering, as handled in the government bulletin sketched by the editors, page 876, Nov. 1. If anybody in these parts winters otherwise than in single-walled hives on summer stands I don't happen to know it. That being the prevailing practice does not mean, however, that some other way, yet untried, might not be better. Yet in talking over Dr. Phillips' contention that packing is well worth while anywhere in the United States, Mr. Allen made a point that seems to me logical: As you come south, the profits resulting from winter packing probably continually lessen. If that is so, somewhere on the way you are likely to cross a line below which that profit may become less than the increased expense. Now I wonder just where that line might be. I judge the bulletin shoves it quite out of the country, while the wintering generally practiced throughout the Southeast might suggest that most beekeepers think it coincides with Mason and Dixon's famous line. But such authorities as the authors of this bulletin command the instant and respectful attention of all beekeepers, so we promise ourselves the satisfaction of experimenting with packing-cases down here—perhaps not this winter, as we haven't

yet a very definite idea of how we would handle it; but we are going to get (and study) Dr. Phillips' bulletin on the subject, and various other suggestions, and next winter we may put half the apiary in winter homes, charging the expense against them, and keeping strict account of the final results (dollars and cents results) as compared with the other half wintered the old way. (By the way, the "strict accounts" of this season are not pretty to look at.)

Another interesting question regarding wintering is in the value of supers in comparison to brood-chambers only. Several articles or letters in recent numbers of GLEANINGS (for instance, from Mr. Roebeling) page 863, Oct. 15) speak highly of the results from wintering with the supers on. At least one of the most successful beekeepers around here reports excellent results from that system. We are leaving on a few supers ourselves this year. Now Mr. Roebeling says his honey for wintering will be found scattered through the twenty frames. The editor, page 834, same issue, warns against too much hive room. If the supers give more space for the bees to keep warm, but no more honey, would they perhaps be more snug with all the honey packed into the brood-chamber, in just the ten frames? As a general proposition, are twenty frames, with a little honey in each, better than ten nearly full, in the smaller space of a single story? [Ten full frames are better.—ED.]

* * *

Now I want to ask another question—a hypothetical one, perhaps the lawyers would call it. You have decided you want your hives, with bees and stores, to weigh, we will say, sixty pounds. The first one you weigh pulls the scales to fifty. "Needs ten pounds," you say. Do you mean ten pounds of sealed honey? If so, how many pounds of syrup, two measures of sugar to one of water, will be required to make it?

Two quarts of sugar weigh about $3\frac{3}{4}$ pounds, and one quart of water about 2 pounds. The two combined make a scant $2\frac{1}{4}$ quarts of syrup, weighing practically $5\frac{3}{4}$ pounds (the combined weight of the sugar and water). By simple calculation from these data it is easy to know either the weight or the measure of both sugar and water required to make any desired weight or measure of syrup. But what weight of syrup is required to make a desired weight of "stores"? [We usually figure on 20 lbs. of sealed stores, including combs, as sufficient for northern wintering. Twenty-five or possibly thirty would be better for the South.—ED.]

NOTES FROM CANADA

J. L. Byer, Markham, Ontario

By the time this is in print, the Ontario convention will be a thing of the past. We are hoping for a good attendance, and feel quite sure that we shall have a profitable time. These annual meetings serve a good purpose in more than one way; as, aside from the possibility of gaining some useful information, the social side is often too little appreciated. "Man is a social animal," a certain writer has said; and when we meet any one without any semblance of this trait we are at once apt to think him abnormal. In our brushing side by side with one another in convention discussions we are pretty sure to get the conceit knocked out sooner or later.

As intimated in my last "Notes," the honey market has been good and is still brisk, at least in so far as I can learn locally. My own crop has all been sold for some time, and I have been forced to return money for orders sent me. While I tried to get honey to supply this demand, prices quoted did not warrant the handling, much as I should have liked to fill all orders that came to me. Of course we did not feel like doing the business at a loss, and at the same time I am pleased that all the beekeepers I wrote also seemed to be getting good prices, as the general market is much more important than any little business I might do in handling some of the honey.

Since Oct. 15 we have had very fine weather here in Ontario, with much less frost than usual at this date. On Nov. 8, and in a sheltered spot, I have just noticed some tender vines still untouched. There should be no excuse this fall in the matter of feeding the bees for winter when such care is necessary, in so far as the weather is concerned, anyway. Our own bees have all been packed for winter for some time now; and during this fine mild weather we have been wondering if it would not have been just as well to postpone this work for a week or two. On the other hand, if weather should have turned out cold and stormy, as it often does at this date, then we should have been sorry bees were not packed.

Mention is made in an editorial, page 688, that, owing to so much rain, a lot of clover is still in bloom, and this will likely

increase the yield per colony here in Ontario, as given in report the editor quotes from. Yes, we have had more or less clover in bloom; but in our locality, at least, "clover out of season," if I dare use the phrase, never yields much honey. Does it do so in other places as a rule? Some years the bees appear to work on clover quite freely during late August and early September; but I have yet to see any surplus stored from it; but, of course, other places may tell an entirely different story.

What would be the advantage if a process of filtering dark honey were to become a commercial success (page 829, Oct. 15)? As I see the matter, it would be better to leave things as they are. The dark honey has a place to fill, even if the price is lower than the white; and have we any assurance that the flavor would be changed by this process? If such is not the case, "filtered buckwheat honey" would still be buckwheat honey, even if white in color instead of amber; and such a condition would not be likely to help the sale of either the naturally white or the artificially colored article. There may be some good reasons for desiring to have the dark honeys made white; but as yet they do not seem to be much in evidence. A number of years ago I remember of this plan being mentioned; but so far as I know it did not prove a success. Perhaps the same thing may happen this time, and so comment may as well be postponed till we have something more definite. [See the statement by L. R. Casablanca, on same subject, page 993, this issue.—ED.]

The question of aster stores has been much in evidence during the past few years; and after all that has been written on the subject is studied, the matter seems to resolve itself into this: Aster honey in some parts of the country is altogether different from what it is in other sections, whether this fact is attributable to weather conditions, soil, kinds of asters, or what not. As stated on page 829, Oct. 15, that these stores are all right if sealed, we should be inclined to agree, judging by our limited experience; but, on the other hand, well-known authorities from the middle South have written me that in their locality even the sealed combs of honey in strong

colonies will, during cold spells, "weep" and break the cappings, and then the honey sours. Whether this is partly caused by the fact that most beekeepers in these localities give no protection to the bees in the winter is another matter; but I suspect this may have something to do with the question. As a matter of experience I can only repeat that at the Lovering yard, where the bees had little but aster honey for last winter's use, no bad effects showed; and in some queenless colonies that must have perished early in the winter solid combs of this honey were in the hives till early spring, and there were no signs of any of it turning sour, although it was quite thin in body when cells were opened.

On p. 793, P. C. Chadwick says, "There seems to be a disposition shown to 'knock' yellow bees." As one who has a few times given the goldens none too good a record, I want to hasten to explain that, if "the wish is father to the thought," I certainly would try to do otherwise, as some very close friends of mine happen to be breeding these bees. Goldens may be all right with Mr. Chadwick and others who have them—in fact, I am sure such is the case; but I want to say without fear or favor that, in our own personal experience, we have yet to get the first golden colony that would measure up to the standard of ordinary bees when all things were taken into consideration. The great majority of those I have tried have been very inferior honey-gatherers; and the few that were an exception to this rule were no use whatever in the matter of wintering outdoors. There is not the slightest doubt about it; that all golden bees I have had have been totally unfitted to stand the rigors of our winters when bees are left outside; and this fact alone condemns them for my use, as I practice that method exclusively. I happen to know that the great majority of the producers in Ontario have had a like experience, so it is not to be wondered at that this race of bees comes in for "knocking" in northern localities.

Any comment I might make on Bulletin No. 695, Washington, D. C., on the subject of outdoor wintering of bees will no doubt be much in line with the fable of the fly and the ox. The fly started to apologize for sitting on the ox's horn, and the latter informed the fly that he didn't even know he was there. But with all due respect for the opinions of the able authors of the work in question, I cannot help thinking that

some of their conclusions are a bit extreme, to say the least.

In regard to the question of stores, and the large mortality caused by said stores being "inadequate," any one who has been at all observant must agree with them fully. The word used is a very fitting one, for it covers the question of quality as well as the amount, even if I have been in the habit of thinking that it was more properly applied to the question of amounts. But to say that "excessive heat production" is such a great factor in causing winter losses appears to me to be "putting the cart before the horse." After all, in plain words it is simply a case of cause and effect. The prolonged cold spells, often accompanied by poor stores in the hive, is the *cause* of all the trouble. The activity, which, in other words, means increased heat production, is the *effect*; so there you are, free to form your own opinion as to whether cold or heat causes the trouble. For my own part I shall continue to believe that cold causes the bees to get dysentery; and when some one in the South proves that heat brought about a like effect, then I shall be ready to change my views.

"The beekeeper cannot apply too much insulating material to a hive" is another statement that many of us chaps in the North will question. The packing at the experiment apiary near Washington, as described in this bulletin, is 3 inches below, 5 inches on ends, 6 inches on sides, and 8 to 12 inches above; and the comment is made that, further north, more would be necessary. Personally I would consider the three-inch packing at the bottom entirely unnecessary, and in many ways a nuisance. Twelve inches of planer-shavings on top is abundant, and I should not want more than 6 inches around sides and ends—in fact, I should prefer less than that at the fronts of hives. Of course the foregoing remarks are only my own personal views; but I fully believe that a moderate amount of insulation along with an abundance of good stores will give results good enough to suit anybody, even in this cold latitude, where we have long winters with sometimes five months without a day warm enough for good bee-flight—at least that has been my experience. One thing the beginner can bank upon is this: Abundance of good stores are necessary; good protection is also necessary, but the stores question is many times more important than all else. This is at least true in our northern sections. Further south, where flights are more frequent, the quality of the stores may not be so important a matter.

BEEKEEPING AMONG THE ROCKIES

Wesley Foster, Boulder, Colorado.

Mr. W. B. Moore, of Illinois, has been in the West for five months looking up beekeeping prospects and a location. He wants (and probably will find) a good beekeeping location with good educational facilities for his children.

Mr. D. C. Polhemus, of Lamar, Colorado, our largest operating beekeeper, had almost a complete failure in honey this year; but to hold his honey trade he has already bought two cars of extracted and considerable comb honey. A very neat little story could be told of his persistence in building up his trade to where he has to buy in such quantities. It has been true for several years that his sales have increased more rapidly than his production, and he owns and operates more than two thousand colonies.

WINTERING BEES.

We have had a very open fall; and up to ten days ago, or well into November, the bees were storing honey from sweet clover.

This is not any too good for the bees, as they will not be able to ripen this honey fully, and it may cause trouble later. Little breeding has been going on except in those colonies with young queens that are not very populous. Most colonies are going into winter in good shape except that they are not up to the average in the number of bees.

THE HONEY MARKET.

Comb honey has moved in fair shape except in a few cases. There has been a slight slump in prices in some quarters for carload lots, but local orders hold up well in price. There has never been a year when it was so easy to get above \$3.00 a case for the better grades. One or two markets report a large supply on hand, and slow sale on account of the high prices.

Early in November several cars of comb honey were offered in the West at \$2.75 for fancy, \$2.50 for No. 1, and \$2.30 for No. 2, with no acceptances. This honey was packed in single-tier cases, and the freight rate is high from these points.

Extracted honey has been selling well, and, with the advent of cold weather, the trade will become brisk. Sales are made at from five cents a pound up, according to color and quality. White honey brings about 8 cents wholesale.

Sugar is now on the rise, and the way conditions are now, some beemen should be

able to sell honey for the same figure as sugar. Such a time is auspicious for extending the use of honey in cookery.

HONEY-LABELS.

Beekeepers should by all means use labels on their honey-packages. A neat label is a good advertisement. The label on a glass package should not cover up too much honey, neither should it be so small that it looks only like a sticker. In choosing a label I avoid white, for the reason that it will soil more quickly. A yellow stock of paper is good, or a blue stock with white letters. The words "Pure Honey" should be prominent, and there should be some directions as to the care of honey.

The gummed labels are much to be preferred for glass and I am using them on tin also; but there is some difficulty in making them stick on tin. I have used vinegar and ammonia to wash the can with before applying the label. Ammonia works the best, but is not very agreeable to handle on account of the odor.

Probably the ungummed label for tin is the best, as it is no more difficult to apply the paste than the ammonia to make the gummed label stick.

EUROPEAN FOUL BROOD.

I have received a letter from Mr. Grover Matthews, of Filer, Idaho, saying that caging the queen has worked better with him than transferring, and that the first outbreak of the disease is the worst, generally. This disease is so variable that the experience of one man may not be the same as that of another. I do not want to speak out too strongly against caging the queens in European-foul-brood colonies; but it has been my observation that transferring and requeening produces results while caging the queens has not. I would not advise any one to temporize with the disease. Generally it works so fast that one is given no chance for temporizing.

Another thing that might be mentioned is this: Do not read everything on European foul brood before you get busy with it if it is in your apiary. A little actual experience mixed with the reading helps wonderfully. Nothing will so confuse one as reading all the contradictory experiences of the beemen printed in the journals. You will not have all their problems in your apiary; and if you try to apply everything you read, European foul brood will likely get the best of you for quite a while.

CONVERSATIONS WITH DOOLITTLE

At Berodino, New York.

WHY THE DIFFERENCE?

"The past summer some of my colonies stored nearly twice the amount of honey that others did. Is this usual? Why the difference? If we can discover the reason we might find a remedy."

There are not many observing beekeepers who have not sooner or later noticed that some of their colonies not only stored enough honey for their own use but have given a surplus of from five to fifty pounds, while most of the others in the same apiary did little more than make a living. This condition is more noticeable in poor seasons than in seasons giving a rich flow of nectar. In a good season it has also been noticed that some colonies gave a surplus little less than marvelous in comparison with others, all having access to the same pasturage, and all coming out in the spring in apparently the same condition. I say "apparently," but it is not often that these conditions will hold good to the beginning of the honey harvest, for many colonies will out-strip others in the brood-rearing race during the first month after they commence active operations in the spring.

We are often told to keep all colonies strong, as it is only such colonies that yield a surplus; but this is not always possible, even were it desirable. With the uneven results obtained from the whole apiary, with colonies apparently of equal strength in the spring; combs, hives, and pasturage apparently the same, there must be other factors not easily discovered to cause such unequal yields.

From years of observation I believe that there exists a certain something which we call a "condition," under which a colony will gather the most honey, whether it be extra strong or not up to even an average. If such condition has not yet been reached, or if it has been passed, the storing of surplus will not be so vigorous as it would otherwise be.

What is this condition? The ideal colony must have a perfect queen; be sound in body, in her prime, vigorous, hardy, and prolific, her progeny active and diligent. But such a queen alone will not make an ideal colony. At the right time—that is, when clover, basswood, or fall flowers are in their prime for nectar secretion—there must be the maximum number of field laborers and plenty of empty comb so that

no time or nectar be lost in the secretion of wax and building of a place in which to store it. The ideal colony must swarm at the right time or not at all—that is, so early that the young queen in the parent colony becomes fertile, and the prime swarm has its combs completed during the first quarter of the blooming of the flowers which give us the main flow of nectar of the season.

The ideal colony must not be over-populous too early in the season. A colony is over-populous when the working force is so great a week before the honey harvest begins that the bees contract the swarming fever because the hive is too small in comparison, and the wax-secreting bees too few. Such a condition seems intolerable to the bees, and they try to help themselves by loafing. Their instinct seems to teach them to begin this loafing even before the hive is over-populous. A colony in such a condition will never perform the wonders in gathering nectar that we may expect from one less populous at the very commencement of such nectar flow. The over-populous colony realizes instinctively that its abode will soon be too small, and the swarming fever sets in; and even a novice knows that such a colony is of little value as a honey-gatherer.

The ideal colony is not kept at home during the best nectar-flow by nursing too much brood. If there is too much brood in proportion to the working force, most of the honey will be consumed by the brood. With bees which rear a large amount of brood during the main nectar-flow, or near its close, although they are strong in bees and the queen faultless, the combs will be mostly empty, and will stay so, unless there is to be another nectar-flow of good proportion from ten days to two weeks later.

One of the great points of superiority with the Italian bee is that, when the big harvests of nectar from the clover and basswood come on, the main energy of the bees seems to be bent in the direction of securing the harvest, brood-rearing becoming a secondary consideration. If, through our management, and with a race of bees which will yield to our control, can be found something that will make all colonies give a yield equal to the very best in the past, so that all colonies will come up to the "high-water mark," a great stride will be made.

GENERAL CORRESPONDENCE

BIBLICAL REFERENCES TO HONEY

BY W. P. ROOT

The first mention of honey in the Bible is in Genesis 43:11. Jacob sends some to the unknown Egyptian ruler who is afterward revealed as his lost son Joseph. Egypt then, as now, was practically destitute of honey flora, while Palestine abounded in it as well as in countless places in the rocks where bees could find excellent shelter all the year. "A land flowing with milk and honey" is a frequent description of Palestine as recorded in the Bible.

In Exodus 16:31 we find the oldest reference to honey as an integral part of human food. The passage would imply the use of honey as a staple article of food in conjunction with other things.

In Leviticus 2:11 is an injunction against the use of honey in burnt offerings. This arises from the difficulty of burning it in the first place, and also from the disagreeable smoke that would necessarily arise from honey on hot coals. The passage indicates a peculiar regard which the Jews had for honey in connection with religious rites.

In Deuteronomy 8:8 honey is referred to as one of the great staples of the promised land. The same idea is repeated in II. Kings 18:32, but in connection with or relation to Assyria, the blasphemous Rab-Shakeh tempting the Jews to submit to the king of Assyria, saying his country had honey as well as Palestine.

In Deuteronomy 32:13, among the blessings conferred on Jacob as a nation he is said to be caused to suck or derive honey from the rock—a graphic reference to the habits of bees in that respect. John the Baptist doubtless obtained his "wild honey" in the same way, as recorded in Matthew 3:4.

In Judges 14 we find the remarkable account of Samson finding a colony of bees in the desiccated carcass of a lion—an indication of the great number of bees then to be found in Palestine. As Samson had killed the lion but a few days before, it might be deemed an unsuitable place for bees; but as many carnivorous animals and insects abound there, it is no uncommon thing to find a dead animal entirely removed in a few hours, all but the bones. This work would be greatly hastened by the intensely warm and dry air of that climate. Later on at a social gathering Samson chal-

lenges the company to mention anything sweeter than honey.

In I. Samuel we read that Saul's army was distressed by hunger, as he had forbidden his men under penalty of death to eat before sundown. They came to a place where honey was found "on the ground," or, as some might understand it, within easy reach. Jonathan, a son of Saul, not knowing of his father's inhibition on food, stuck a rod in some comb honey, and, eating it, was greatly strengthened and revived. When told of what his father had said, he said he wished they had all eaten of the honey so that they might have punished the Philistines more severely. Later, when Saul insisted on his inhuman order being carried out, the people arose and prevented it. The incident shows the salutary effect of honey, even when eaten in large quantities on an empty stomach, as was doubtless the case with Jonathan.

In II. Samuel 17:29 we read that Shobi, an Ammonite, one of a nation very unfriendly to Israel, with others brought to David, when he was fleeing from his son Absalom, a large quantity of delicacies, among which is mentioned honey. This indicates a more general use of honey than we now witness.

In I. Kings 14:3 we learn that the wife of Jeroboam the king was directed to take with her a cruse of honey when she went to confer with the prophet Ahijah. This would imply that honey was a fit gift even for royalty itself to offer; and the prophets then were held in greater esteem than kings.

During a great religious revival under Hezekiah, as recorded in II. Chronicles 31, a prodigious quantity of the best of the land was brought to Jerusalem to make a national holiday, and honey is mentioned as being one of the food supplies; and even to this day the Jews make much use of honey in their numerous festivals, all of which are of a religious nature.

In Job 20, Zophar, in replying to Job, says the wicked shall not see the brooks (streams) of honey, this indicating, probably as long ago as the time of Abraham, that honey was a staple article of food.

In Psalm 19 David compares the judgments of God to honey as if that were the highest form of praise for what he consid-

ered delectable. In Psalm 119 the same writer uses the same metaphor in speaking of God's words. Probably honey reminded him of how near it came to costing his friend Jonathan his life.

In Psalm 81:16 David says honey is one of the good things God would have given to the wicked had it not been for their perverseness. Here, again, honey is spoken of as being found in the clefts of the rocks.

In Proverbs 24:13 the writer advises his son (pupil) to "eat honey, for it is good." In chapter 25:16 the same pupil is warned not to overeat honey, but to stop when he has enough. The warning shows the liking the young people had for honey in those ancient times.

In Isaiah 7:15 is a remarkable passage predicting that the Messiah, Christ, would eat honey, which prophecy was fulfilled in Luke 24:42, where Jesus was regaled with honey after his resurrection from the dead.

In Jeremiah 41:8 the treacherous Ishmael is persuaded not to kill ten certain men whom he had captured, as they had treasures of honey and other things hidden in a field. Probably he cared more for their honey than for their lives.

In Ezekiel 3:3 the prophet is commanded to eat a roll of manuscript, which he did—probably figuratively. To give an idea of its agreeable effects he says it was like honey for sweetness. In chapter 16 honey is spoken of as one of the great blessings God had conferred on the rebellious city of Jerusalem. In chapter 27 of the same book, honey is spoken of as being sold to the merchants of Tyre—another indication of the abundance of honey among the Jews.

In Matthew and Mark honey is said to have been a part of the food of John the Baptist.

In Revelation 10:9 John was commanded to eat the book. This was bitter in taste, but as sweet as honey afterward. This was possibly in vision as in the case of Ezekiel.

In several places in Proverbs honey is spoken of as a standard of sweetness. Where honey-comb is spoken of in the Bible as being eaten, we should always understand comb honey; but the Hebrew word "dabash" indicates what we used to call strained honey, the same word being called "debs" by the Arabs of today when speaking of crushed comb honey.

Medina, Ohio.

ONE WOMAN'S WAY OF LIFTING SUPERS

BY FLORA M'INTYRE

Grace Allen is puzzled over the lifting problem. My mother does considerable work alone in the apiary, and she manages the lifting of heavy supers thus: Carrying along an empty super when she goes into the apiary, she places it on the ground at the back of the hive to be opened. After prying the super free and applying a little smoke she half slides, half swings the super along on the empty one in the rear. When she is ready to close the hive she swings the super back on to the brood-chamber in the same manner. In this way the heavy super does not have to be lifted or lowered from the level at which it rests, and that eliminates what is usually the very hardest part of the lift. Not long ago my mother wished to put a super

of empty combs under one that was full of honey. She lifted the full one off in the manner described, and found that it was very heavy. After putting on the super filled with empty combs the problem was

Swing the heavy super on to the empty one.

how to raise the heavy one up to the third-story level. It seemed about impossible until the inspiration came to place an empty super on top of the hive and transfer the heavy combs one by one. This method is slow, but perhaps not as much so as waiting for some one to come and help. It could be used in moving the second story if necessary; but the mother is small, and not at all muscular, and she has found that an empty super to swing it on to is all that is

needed. However, she says that, if she were starting in business with a new equipment she would try the shallow supers because of the greater ease in handling, and in spite of the fact that the brood and super combs would not be interchangeable.

Ventura, Cal.

[The plan here outlined is perfectly feasible, as we have tried it on numerous occasions.—Ed.]

BEE-NOTES FROM HOLLAND; OUR BEEKEEPERS' ASSOCIATION

BY J. H. J. HAMELBERG

We have only one association of beekeepers in this country. Considering, however, that the whole of Holland has only about six million inhabitants, this one association may be said to be all that is wanted. At the beginning of this year it counted 6574 members (which means one member to every 100 inhabitants), divided over 121 districts, each of which has at least 25 members. Each district has its own officers, and can make its own by-laws and regulations when these do not conflict with the statutes of the association or with the resolutions of the annual conventions.

The yearly contributions of the members is one guilder (40 cents), each district having control over the contributions of its members, under the obligation, however, of holding three-fifths of these at the disposal of the General Board of Directors. Persons wishing to become members, but not desiring to reside under the district board of their places of residence, can do so; but the contribution is then doubled. Voting for membership is not required. To become a member one has only to send in his name.

Every year, in April, a general meeting of the members takes place. Each district can send a delegate to this annual convention, who then represents the entire district, and has to vote in accordance with the opinions expressed by a meeting of the district members, previously held, or according to the instructions the district board may have given him. He may bring out one vote for every twenty-five members of his district, but is never entitled to more than six votes. Once a district is represented by a delegate, its other members, although having the right to assist in the meeting, and there have their say, are not entitled to vote, neither have the members not belonging to any district such right (which seems rather hard on them).

It is to be regretted that this annual convention lasts only one day. The reading of

the yearly report of the secretary, the discussions about the budget, the election of commissions, and other official business, take up so much of the meeting's time that there hardly remains an opportunity for the discussion of the pros and contras of different matters recently brought forward in bee-management, nor for the exchange of experiences of the practical beekeepers present at the meeting.

As evening approaches, one may notice every now and then a member or district delegate who has to catch the last train to reach home that night, leave the assembly, and, as a rule, the latter part of the program has to be hurried through. No wonder that, except the district delegates, so very few members assist in these annual conventions where they seldom hear anything of practical use to them.

This year two papers were read at the convention, one treating on the rights on stray swarms, the other discussing the desirability of introducing a species of red clover accessible to bees, and of the same value for feeding purposes as the red clovers cultivated in this country. Both lecturers proved to be well posted in the matters treated by them; but their practical value to an audience of beekeepers seems rather doubtful. We have no legislation on the rights of ownership of stray swarms, and it is, in fact, of little value to the practical beekeeper to hear what should be, but what is not. And as for the desired species of red clover (the benefits of which will hardly need to be demonstrated to beekeepers) this is a subject for the researches of our agricultural experiment stations, while the introduction of such a species, whenever found, would surely be in better hands by the farmer than by the beekeeper.

Although one can appreciate the attempt of the General Board of Directors to make the annual conventions more attractive to the members, it cannot be doubted that such

Apiary of W. van Os, Leerseem, Holland. Mr. van Os is secretary of the Holland Association of Beekeepers.

purpose would be realized sooner by giving the members an opportunity of hearing at these conventions something of practical value to them than by asking them to listen to the reading of treatises, however learned and thorough, on subjects like those treated this year—the one being more appropriate in a meeting of jurists and legislators, the other being a matter to be submitted to our Agricultural Department. Once the conviction gained ground with our beekeepers, especially with the “small fry” among them (who are most in want of instruction), that their attending the conventions would lead to their better knowledge of profitable beekeeping, the meetings would surely be better attended, and our practical beemen would not consider having done their duty by delegating one of their district members to these conventions. And as will be shown in following articles, it cannot be said that our beekeepers are not in want of some better ideas about modern beekeeping.

The association issues a monthly periodical, usually containing twenty pages of reading matter in small octavo. It contains the official communications of the General Board of Directors and of the district boards, articles by the editor and of the members, and, occasionally, extracts from *GLEANINGS* and other foreign bee-papers. There can be no question that the editor tries his best to give his readers something in good style and form; but he is rather handicapped by the small amount (\$800 a

year) put at his disposal for the paper, the printing, and the gratis distribution of the periodical among the members. Considering his salary of \$100 a year, the editor's work cannot be considered otherwise than one of love; and to expect more of him would simply be presumptuous.

For many years the association has been presided over by G. Baron de Senarels de Grancy, a courteous aristocrat of the old French school, and at the same time an influential man who felt warmly for beekeeping and beekeepers. Advanced age and want of time obliged him last year to request not to be re-elected, and, although with great regret, the annual convention had to respect this desire. During his long term of presidency, the association has brought about some very good measures; *e. g.*, a government grant for the appointment and salary of an official to instruct and advise our beekeepers by visiting their apiaries and by holding lectures all over the country. I don't doubt that Mr. van Giersbergen, who holds this position at present, and who, we beekeepers hope, will be continued in it for many years to come, will often meet with the same distrust our first professors in agriculture met with on the part of such people as believe practice to be all and science nothing. It is manifest, however, that this want of confidence is gradually disappearing, and it has often been demonstrated how his lectures take.

Another good thing obtained during the presidency of Baron de Graney has been the freedom of duties on sugar (which are high in this country) used for feeding up bees for wintering. Before distribution among beekeepers this sugar is mixed with some ingredients to unfit it for housekeeping purposes, usually with "paprika" (red pepper, ground very fine). Besides, every beekeeper is entitled to only a certain quantity per colony (usually fixed at 16½ pounds), and our customhouse officers have the right to visit all apiaries to ascertain that not more sugar is applied for than the amount to which the owners are entitled. This adulteration does not seem to injure the bees. They take up the syrup readily and winter well on it. Until recently only white granulated beet-root sugar had been distributed; but last year the General Board of Directors decided to purchase unrefined sugar, which has not been a success, and won't be repeated. It seems to have been done for economy's sake, the sugar having gone up in price considerably on account of the war. But, as I have been told, some beekeepers have, unfortunately, suffered severely on account of this economy.

Our association has also introduced a diploma for beekeepers. Any one desiring to obtain it has to pass an examination before a commission appointed by the General Board of Directors, and of which the bee-expert, before mentioned, always is a member, the other members being chosen among well-known beekeepers and officers of the association. The institution, however, does not seem to be very popular, as very few practical beekeepers submit themselves to this examination. Neither is this to be wondered at. One may be thoroughly well acquainted with the methods of profitable beekeeping without being able to expound the anatomy of bees and flowers, or without knowing the construction of different makes of hives, as is asked by the examiners. The practical demonstration that candidates have to give of their ability to handle bees is necessarily limited for want of time, only two hours being put aside for it.

When wanting help, most beekeepers will rather judge a man's ability after having had him at work for a day than by his holding the association's diploma. Still, the possession of it proves the holder not to be a stranger to bees. As such it has some value; and the fact of its existence will help to convince the outsider that there is something more in beekeeping than putting down a hive in spring and gathering the honey in autumn. And it does not appear

superfluous to combat this idea, for even our government seems to hold it.

We have government experiment stations galore for the promotion of the interests of the farmer and stock-breeder; but in the matters of beekeeping and poultry-keeping, very little is done by our government, which mainly contents itself by giving a grant to our beekeepers' and poultry-keepers' associations. Having done this, it seems to think that it can leave the development of these two branches of agriculture to private and individual initiative. It has not awakened out of its lethargy I mentioned seven years ago, and, as yet, it does not seem to have the least idea of the scientific problems attached to the full development of beekeeping and poultry-keeping; for if it had, it surely would not believe that the solution of these problems will ever be reached by giving the respective associations grants of between \$1000 and \$2000 a year, which amounts would not constitute even a reasonable salary for one scientist to devote his time and knowledge to these problems, not to speak of the cost of buildings, grounds, and other supplies indispensable for thorough scientific researches.

It must be said that the association with its limited means does what it can do in this matter. A few observation stations have been erected, the managers of which regularly send in the data of the temperature and rainfall at their apiaries, and of the increase or decrease in weight of their colonies, which data are published in the monthly periodical of the association. Valuable as these observations may be, they won't bring us much nearer to rousing our government into action.

For this reason it was very wise on the part of one of our members to move at our last convention that the General Board of Directors take the initiative for the erection of an experiment station for the promotion of beekeeping, and the board has already taken steps in this direction. But at the same time it would be but right, I think, for our beekeepers to point out their interests to their representatives in Parliament, and refuse their support to such candidates for election as are not prepared to further these interests. At present, hardly a voice is ever raised in our House of Commons for the promotion of the interests of beekeeping and poultry-keeping.

But this state of things would surely become otherwise if all beekeepers and all poultry-keepers in the country would club together and give their support to only such men as are well convinced of the absolute

necessity of improvement of the present conditions by the government.

Last, but not least, the association tries to come to a more uniform packing and grading of honey, and to a better co-operation among beekeepers in the matter of disposing of their crops and the purchase of their supplies. To further this purpose, a chamber of commerce (as it is called) has been instituted; but whether or not it will prove a success remains to be seen. The

interests of many beekeepers would certainly be greatly advanced by a general office, as instituted. But opposition from the trade is surely to be reckoned on, and the great difficulty will always be to find the right man to head such an office, while it won't prove such an easy matter either, to convince the smaller fry that co-operation in these matters must necessarily result to their profit.

Soest, Holland.

ANOTHER WAY TO GET A START

BY DR. G. R. RICHARDSON

In the fall of 1912 I happened to remember an old-time beekeeper who had died several years before, and I wondered if there were any of his old hives still left. I investigated, and found that out of an original 700 there were 240 still holding together.

I interviewed the widow, and she asked 20 cents apiece for them just as they were. I finally offered her \$25.00 for the lot for kindling-wood; and after properly demurring she accepted my offer, and I am sure that she at the same time smiled in her sleeve. I did not at that time tell my wife how much I really did pay for them, nor did I tell her that it cost me a dollar a load for ten platform hayrack loads to have them hauled a mile. The teamster agreeing to take a load of broken covers for one of

the dollars somewhat quieted my conscience, and I started in to clean up the immense pile of hives. By the next spring I had them sufficiently cleared away to be able to find the barn, and furthermore had sold the old worm-eaten combs for \$10.00.

These hives (Fig. 1) were 26 inches long, 16 deep, and 41 from the ground to the

Each hive rested on four legs.

The hives were each over twenty-six inches long.

middle of the cover when the super was on. Each hive stood on four legs nailed to the ends of the brood-chamber, which was 18 inches high in front and 12 in the back, and held 14 frames, with the bottom-board nailed on, and sloping from back to front (so that the worms would fall off the combs and roll out the entrance!) which extended clear across the front, and was hinged so it could be opened fully three inches.

The frames (see illustration) had thirteen inch top-bars with a three-cornered piece to fasten the foundation on, and with closed ends. The bottom-bar was at an angle to follow the bottom-board, and rested on a

cleat at the front; and the back lower corner rested on the bottom-board. Two follower boards were used, one in each end, and they were held in place with two wedges to each board.

The bee-space between the top-bar of the brood-frames and the bottom-bar of the section-holders was all the way from an inch to two inches, according to whether they

The bottom-bars of the frames were at an angle to follow the bottom-board.

stayed on the cleat or dropped off. And the supers—such supers! Twenty-seven inches from end to end, 12 inches from top to bottom, and 18 from front to back, with 12 section-holders, each of which would hold six sections. I know that they would hold the sections, because I tried to get some of the old ones out. Each had two three-inch strips of tin nailed on one side, presumably for separators; but I may have been mistaken as to their use. It may have been to keep the sections from coming out; and if that was what they were for they were a grand success. I do not wonder that this old-time beekeeper was of an irascible nature.

The lumber in these old hives was soft white pine, light in weight, a full inch in thickness, straight-grained, and all nailed with cut nails, mostly ten-penny casing. Just imagine pieces of pine 24 x 26 inches without a knot, and so soft that a ten-penny nail would not split one when driven half an inch from the end! I certainly did get my \$25.00 worth in working them over during the winter evenings in my shop in the furnace-room. I made fifty good hives

of another and better pattern, of which I have never seen a description in any book or paper, although it may have been described before my time. It was not an invention of mine, but of a very successful beekeeper of my acquaintance. With his permission I should like to tell about the hive at a later date, as it embodies some features that I think excellent, especially in the super. This has no T tins nor other support, but is so made that the frames are self-supporting.

Besides these fifty hives that I could not buy for less than \$4.00 apiece, I have kindling enough to last several years, all cut and resined, and have so far sold nineteen old hives, just as I got them, for a dollar apiece, and have four more yet to sell.

With the best of the lumber that was left after building my fifty hives I then built a house, or shack, ten by twenty, with a porch of the same dimensions, in which I live with my family of four during the summer.

I did not buy a stick of lumber, not even a two-by-four which I also made by nailing pieces 26 x 11 together, breaking joints, and then ripping. These gave me two-by-fives that I used for joist and studding.

In the new hive the super is so made that the frames are self-supporting.

The roof and sides are made by nailing the end boards and follower boards, which are 12 x 14 (of which I had over a thousand) to strips of the 26-inch pieces, and then to the studding. The roof is sheathed with these small pieces, and then covered with regular roofing-paper, which is painted with powder paint. The cost of the

With what was left I built a summer cottage for my family.

whole building did not exceed \$20.00, the largest part of which was for the roofing. Even the nails were, for the most part, the old nails, of which I picked up and straightened out over 67 pounds. I did the work all myself with the help of a friend who is also a little-red-hatchet carpenter, and did not lose a single day from the office.

The shack is located on a hill overlooking a beautiful valley, fifteen minutes from town on the interurban line, and is surrounded by fine oak-trees of several species; and, besides being a delightful place to spend the summer, it is a good location for bees. We have plenty of white clover some years, acres of sweet clover every year; willow, some basswood, dandelion by the acre, and plenty of catnip. Hound's-tongue (*Cynoglossum officinale*) is simply taking the pastures in this section. My wife is my partner; and what I do not think of she certainly does; and when I become discouraged she enthuses, and *vice versa*.

The first year we started with two colonies of bees. One of them we moved from town, and the other was a swarm from a neighboring farm. Something happened to the queen we took from town, and the other colony we evidently managed to death—any way, we started over again the next spring, this time with two queens and two half-pounds of bees. One of these queens went the way of the first, and we bought another,

which we succeeded in introducing successfully. The next spring we again started all over again, this time with two full colonies, which we tried to divide by removing the queens and waiting for queen-cells. One queen we killed outright while trying to clip, and the other took a swarm out while we were looking over the frames. They did not even take time to settle, but evidently knew where they were going, as we chased them nearly a mile through the fields without finding them.

We succeeded in making them queenless, and then some, as there were no eggs in either hive. After waiting in vain for queen-cells we bought six virgins which we introduced. We were successful with four, and in the mean time caught a fine swarm in a decoy hive. So we now have the best start that we have ever had, and are once more enthusiastic. We have learned a few things about bees in our three years' experience, and comfort ourselves with the thought of Dr. Miller's eleven years at beekeeping with only two colonies to show for it. We think that we may yet win out.

We certainly have the love of the pursuit all right, and are long on theory but short on experience. We are acquainted with them all, from Dr. Miller to Doolittle, and from Miss Emma Wilson to Frank C. Pellett—also Dr. Bonney.

Princeton, Ill.

A NEBRASKAN'S HONEY-HOUSE

BY LOUIS MACEY

When I first began keeping bees I used a spare upstairs room in the house to store the honey and odds of equipment, together with such supplies as would be damaged by the weather. I also used the kitchen as a workshop for putting up sections and repairing hives; and as honey tasted mighty good those days, the "missus" was very indulgent of the "muss;" but when it came to scraping sections (even with plenty of papers spread around), that was a different kind of "muss." As I got close to 70 or 75 colonies, and the taste of honey grew old, and the stored honey and junk overflowed into the attic over the shed room and filled it up, I saw I had to have a special building.

As I had done well with my bees, liked the work, and felt that I was in for keeps, and as I also gained some experience of what a mouse can do in the way of damage, I decided on cement. We made the blocks ourselves, using a fifteen-dollar mail-order-house machine, and a rich mixture of one part cement to $4\frac{1}{2}$ parts of river sand and gravel.

Let me say there is a big difference in concrete, and especially in concrete blocks. Turning the mixture over two or three times with a shovel is not mixing as concrete should be mixed. We have found that, by slinging and scattering each shovelful we could make the dry mix quite uniform by four times over, no less.

We made only about 100 blocks a day; but they were all thoroughly tamped. A fellow came by who boasted that he had made 200 a day, right along, and done his own mixing. We let him show us how quickly he could make one. He certainly did not take one-third the time we did, and the block looked all right; but an hour after he was gone I tried the blocks with my finger. Ours were firm and solid; but in the one he made I could easily make dents a quarter of an

inch without causing any bulge around them. It is porous blocks of this kind, barely hanging together, that let so much water through and stay wet so long. It certainly is a mistake to build a permanent structure out of a lean mixture, half mixed and half tamped. It pays to do it right.

The house we put up is 16 x 20 ft., $1\frac{1}{2}$ -story. The lower floor is cement, with a very hard smooth finish, and there is also a cemented pit, 6 x 6 and 3 feet deep, in one corner, so we can set a can under the extractor.

There is a deck above this pit, which is 3 feet lower than the main upper floor, and serves as a landing for the turn of the stairs.

We used a total of 106 sacks of cement, costing us here \$68.90; and the rest of the

The house cost \$121.60, not including our own labor.

material—lumber, door, windows, shingles, hardware, etc., came to \$52.70, or a total of \$121.60 for the house as it stands, not including our labor, of which I kept no account. We did all the work ourselves, mostly at odd times. It is as near dust-proof as we could make it, the plates and end rafters being cemented on, and paper laid under the shingles.

There is just one thing to be desired: It is hard work lugging the honey up out of

the pit around up the stairs. I shall soon have to have a larger extractor, and should like a honey-pump and a big tank upstairs with a pipe and faucet to draw off from below; and here's the problem: Contrary to Mr. Wilder, our early-gathered sweet-clover honey granulates (if anything) worse than the late-gathered crop. The first is generally aggranulated solid before I finish the last.

If I let it go till I get a "big tank" full I shall certainly have to heat it some way.

I have thought of a steam coil or a double tank with space for circulating hot water between, but these would be expensive, and even then would not clear the draw-off pipe.

I shall appreciate any suggestions from those who have had experience in this line. "I've got to do sumpun."

BEE STINGING BEE LOSES STING

BY C. E. BARTHOLOMEW

This photograph will no doubt settle all controversy as to whether a bee loses its sting when used against another bee. While the writer, in company with Mr. Frank C. Pellett, State Bee Inspector of Iowa, was visiting the apiary of Mr. Tinsley, of Ames, Iowa, a swarm was observed leaving the hive. The three of us placed ourselves in front of the hive near the entrance to observe if possible the queen as she left the hive to go with the swarm. She came out on the alighting-board, but, frightened by our presence, no doubt, returned to the hive.

The swarm, not being accompanied by the queen, began returning; but before we had noticed the movement many of the bees, probably because we were standing there, began entering two adjacent hives. A small war ensued in which many of the bees lost their lives. A large number of the dead bees contained the sting of their opponents; and as Mr. Pellett had his camera with him we fortunately obtained this photograph.

Ames, Iowa.

Many of the dead bees contained the sting of their opponents.

THE NEW EXTRACTING APPARATUS

BY R. F. HOLTERMANN

We have had another season's experience with the twelve-frame honey-extractor, the honey-pump, the steam-heated honey-knife, and the wire-cloth bee-escape board.

Last year we had a very poor honey crop; but this year the crop was good enough to give everything a fair test. I am thoroughly satisfied with all. The steam-heated knives are a great help in uncapping. We have not lifted a pound of honey into our six-foot-high honey-tanks, and the twelve-frame honey-extractors with their friction pulleys are doing their work quickly and well. My son Glen removes a portion of the honey in one side of the comb, then reverses the reel and cleans that side,

turning again and emptying the first side. The saving resulting from thorough extracting is no small item. So much for the inside work.

OUTSIDE.

When it comes to the outside the wire-cloth bee-escape board has simply revolutionized the work here. We carry one bee-brush for cases where there is brood in the supers; and this year in extracting four apiaries we came across one case where there was no brood in the super, and yet the bees did not pass out of it. These wire-cloth bee-escape boards are an unqualified success, and I say this without a moment's hesitation, knowing that there have been

some adverse reports. They will work wherever the solid bee-escape board will work. In speaking with Mr. James Armstrong, Cheapside, recently, a man who is well and favorably known as thorough in what he does, he said, "One must remember that, unless the bees are doing some work, they may remain contented in the super, and the escape be of no avail." People who report

unfavorably on these escape-boards have certainly not been thorough in their work or are not conversant with the conditions under which bee-escape boards work, or else the bee-escapes themselves are not made right. This might easily be the case. If that were true, they would not work on any other board.

Brantford, Canada.

FEEDING SUGAR TO INDUCE QUEENS TO LAY LATE IN THE FALL

BY G. T. WHITTEN

By feeding two or three tablespoonfuls of sugar syrup or cheap honey a day to a colony after the honey-flow is over, or between the main and fall flow, I have found that the queen will continue to lay until late in the fall. This will keep the hive full of young bees at all times so they will be able to cover a large amount of brood and save it all. Double-walled hives should be used if possible. If single-walled hives are used they must be packed early.

A queen at any time of the year will regulate her laying to correspond with the amount of food which comes in. The amount of stores already in the hive has little if any effect on the queen's laying. I found that the egg-production depended on this in-coming food. This feeding should be regular, steady, and in small quantities, rather than in large quantities at one time.

I discovered that, by careful study of general conditions concerning the honey-flows, I could have all colonies strong at the right time. To have them well supplied with young bees late in fall gives strong colonies in spring.

When feeding bees in early spring or late fall, care must be taken, because they use up the food as soon as it is given them. Becoming excited they rush out to seek more food. It is often too cold for them to

return, hence the danger is great in thus feeding, because many bees are lost. I close the entrance of the hive with a wire screen until the bees have settled down again.

The best way to do this feeding is to cover the top of the hive with a wire screen, then place an empty super on the hive, and feed over the cluster.

Take a glass jelly-tumbler. Punch four or five very small holes in the metal cover, and invert it over the frames on top of the screen. The cover of the hive may be removed, and the food may be placed in the super at any time without disturbing the bees or attracting robbers. After many experiments I have found this to be the safest and best method of stimulative feeding. If this method is followed carefully, each colony should be in condition to divide in spring early enough to build up to two, at least, for the honey-flow when it comes.

After a careful examination in the spring, those that are not building up in a satisfactory manner should be fed as suggested in this article.

Each colony should have not only sufficient stores of food for the winter, but "some more," for one cannot have too much food therein. The bees use the surplus to good advantage in the spring.

Hartford, Ct.

APPLES, CHERRIES, PEACHES, AND BEES

BY C. A. OLDMAN

My apiary of 56 colonies is situated in a rather ideal spot, being located on the end of a 16½-acre farm owned by my brother. He has 8½ acres in orchard, consisting of 775 apple, 175 cherry, and 50 peach trees.

The board fence shelters the northwest side, fir-trees the north, and a high hill (from which the photograph was taken) about 150 yards from the hives shelters the east side. The south side is somewhat ex-

posed; but I have planted a hedge of flowering currants to provide shelter from this quarter.

This location is about three-quarters of a mile from my home, and I moved my apiary here at my brother's request. He wanted my bees to fertilize his fruit-bloom, and I wanted his fruit-bloom honey. Although, occasionally, when my brother is cultivating his farm near the bees, and my

A New Zealand apiary in an ideal spot.

hybrids get too fond of him, the air gets a bit blue, yet we are both well satisfied with the arrangement.

My hives are arranged in groups of four (similar to the plan in the A B C, but omitting the center hive. I prefer this arrangement to many others I have tried. The photograph was taken with the orchard for its objective; and, being taken from the end of the rows, it does not show the apiary to the best advantage.

My honey-house is 10 x 10 ft., made of corrugated iron, and is used only for extracting. All combs, honey, etc., are taken home after extracting. On the left a portion of my vegetable-garden is shown, and

a creek runs right around the garden and in front of the apiary, but does not show in the picture. Between the apiary and the hill from which the photograph was taken there is about three acres of lucerne (sweet clover); just past the board fence is a crop of partridge peas; next mangolds; then oats in stack, and then the apple-orchard, with the peach-trees up next the house, and the cherry-orchard on the left side of the house. Another orchard of about three acres adjoins my brother's on the left of his cherries.

In the background are the Waiau River and distant mountains.

Waiau, N. Z.

EUROPEAN FOUL BROOD NOT FORMIDABLE TO THE EFFICIENT

BY J. E. CRANE

Mr. R. F. Holtermann says that for years he has promised that when European foul brood struck his bees he would throw up the sponge and walk out, leaving the outfit behind him. Well, if I am not surprised! One of our most prominent beekeepers ready to haul down his flag and run! He says further he may do it yet. I hope not. Most

of our troubles seem greater at a distance than close at hand, and this is most certainly true of European foul brood.

The shiftless beekeeper may well regard this disease as a serious matter, if not an actual calamity, for it is almost sure to wipe out his "bee-ness" before he knows what is the matter; but for Mr. Holtermann

to run is unthinkable. Leave that for the careless.

I called on one such this very week. He had twenty-five colonies left, but I would not give a cent apiece for them to keep. The wax-worms had already destroyed the combs in a large number, and those left were fast reaching the stage when the worms will come into full possession. I advised him to treat the whole to the fumes of burning sulphur, strain out the honey in the old-fashioned way, and make the rest into beeswax.

There are others who have no trouble, although this disease is on every side of them. One extensive beekeeper even told me that it was a blessing in disguise, as it cleans out the small slipshod beekeepers and leaves the field all to himself.

If we are to fight this disease we must know its strong points as well as its weak ones, that we may fight intelligently. To begin with, European and American foul brood are as distinct from each other as two diseases well can be. I have had a better opportunity to study European foul brood this season than ever before. I find one of the most striking differences in the two diseases is in the rapidity with which it spreads. American foul brood may be in a hive for years, and yet the colony do a fair business, while with European foul brood it very quickly runs down. Not only does a colony run down quickly, but it spreads from hive to hive with great rapidity; hence the necessity that the beekeeper, where this disease exists, be able to recognize it at once and apply the remedy. If the colony is small it should, if badly infected, be broken up or disturbed at once. If of fair strength the queen should be removed, which will stop the spread of the disease in the hive, and after two or three weeks a

young Italian queen introduced, or a virgin in a week or ten days.

Some time in June I called on a lad, perhaps thirteen years of age, who had the care of ten or twelve hives. I found two of them had European foul brood. I gave him the above directions, and when I called on him in August those colonies were as vigorous and healthy as one would care to see. I have seen other colonies this season clean up in the same way.

Now, here is a very curious thing: If we were to take a colony with American foul brood and cut out every cell of diseased brood it would be about as sure to come down again with disease as it is to live. That has been my experience, while with the other disease the hive may be half full of honey. If you give the bees a chance they will clean up and remain free from disease, with a new vigorous queen, provided the colony is of sufficient strength.

I am inclined to doubt Mr. Holtermann's theory that bees from diseased colonies carry the disease germs to flowers, and these bees from healthy colonies take the germs to their own hives, although I have no way to prove he is wrong. The past season a number of colonies were brought from a yard where there was some European foul brood last year. Several of these came down during the spring with European foul brood, and the disease spread in this home yard; but in nearly every case it spread to those nearest the diseased colony. Now, if the disease had spread by way of the flowers it would be as likely to appear in hives furthest from the ones that were diseased as those nearest; so I have come to think that the disease spreads largely or often by bees drifting from a diseased colony and entering, by mistake, a healthy hive.

Middlebury, Vt.

THE CURIOUS SEASON IN CENTRAL WISCONSIN

BY E. E. COLIEN

The beekeepers of central Wisconsin rejoice because of the realization of a bountiful crop of honey this past season, and the very promising prospect for another good harvest the coming year. The season just closed was most emphatically one replete with quick and striking changes of weather conditions that brought hope and almost despair in quick succession.

The heavy fruit-bloom of this section presaging a fine start in brood-rearing was cut short by a long spell of cool cloudy weather and heavy rains. This long-con-

tinued cool moist weather, however, started up the white clover, and oceans of bloom raised the beekeepers' spirits. But the spread of beautiful white had no nectar in it with its first appearance, when, presto! almost in the twinkling of an eye, with the coming of a spell of normal warm weather the floral kingdom seemed suddenly, as if by magic, filled with sweets. One of Wisconsin's best honey harvests was on.

The beekeeper who was ready, and supplied his colonies with supers, surely had "no kick coming" on account of a short

A. J. Knox's apiary in winter quarters. See page 905, Nov. 1.

crop this year. I took off over a ton of choice white-clover comb honey from forty colonies of bees, spring count, besides securing thirty colonies of increase.

Basswood, strange to say, had absolutely no nectar in its bloom here this year. But white clover, alsike, and sweet clover made up the deficiency. White clover was everywhere in evidence the entire summer, the bloom continuing all through September.

Besides a bountiful crop of surplus, the late clover bloom and other nectar-filled flora, coupled with desirable nectar-gathering weather, enabled the bees to fill the hives to their capacity with the best of wintering stores.

The late warm seasonable rains have put white clover in the best possible condition for wintering.

Manawa, Wis.

HOW FAR DO BEES FLY?

BY F. M. BALDWIN

This much-mooted question is often discussed by Mr. Clute and the writer. We are inclined to believe that the distance a bee will work from the hive is over-estimated. We were much interested by the light Mr. Clute's observations threw on the Florida bee. In other climes the bee may travel further afield; but down here she is not much given to long flights. But before I set down the observations let me say that it is not wise to deduce from this anything as to what bees will or will not do in other sections. These observations give light, if at all, on the Florida bee alone.

Reference was made above to the thirty colonies that stored mint honey. They are in the midst of square miles of mint, and seem to care only for mint. Less than a mile north of them is a vast stretch of smartweed. It comes in after mint is out

of bloom. A flight of less than a mile would have put this yard to work on it, but no trace of that nectar is in the supers.

The fields of mint run south from this yard nearly three miles, and then give place to a vast area of smartweed. Three-fourths of a mile inside the line where this last plant begins and the mint ends is yard No. 2 of 142 hives. Here the supers were filled with smartweed honey but no trace of mint—only three-fourths of a mile, but no nectar gathered at that distance.

The third yard is south of Lake Jessup half a mile. Perhaps the lake is three-fourths of a mile wide here. That would make bees fly a mile and a quarter for the smartweed that abounds on its north bank. This yard is in an orange and tupelo section. There is plenty of honey from these in the hives, but none from smartweed.

A word to back this up from our experience in this county (Manatee). When I came to the county I stayed at Parish, a village set among orange-groves. I bought a few bees and transferred them from old box hives. I cut bee-trees in the woods, and transferred to the hives. I expected these bees to fill up on wild sunflower in

October. There was a vast field of it a mile northeast of my yard. In the early fall it burst out into acres of gold, a thing of beauty and a joy to all. The flowers were full of nectar, thousands of pounds of it, but none got to my hives. So far as I was concerned these flowers were born to waste their sweetness on the desert air—dollars upon dollars' worth of honey, but I got none of it. So much for thinking that the Florida bee would

gather sweets and bring them home if they were within a mile or two of the hive. Money was lost because of an error in judgment based upon the old belief that bees work a long way from home.

One more experience because it seems to bear upon this matter. Mr. Clute and I have bees in town, Palmetto. A mile north is the 450-acre grove of the Manatee Fruit Co. They keep bees to pollinate their fruit. It adds largely to their yield, but they are busy with other things and don't care to bother with the bees. They have turned them over to Mr. Clute who works them for half the profit. The big grove is full of

Spanish needle, which last fall secreted lots of nectar. The hives in the grove were filled with honey. Our bees a mile away got very little of it. What little they got came, in my belief, from the weeds that are scattered here and there in small patches in the back yards of the town.

Please don't misunderstand. It is not the

Winter case made of clapboard, siding, as used by A. J. Knox, Orono, Ont.
See page 905, Nov. 1.

intention to show that bees never go a mile or more for nectar. But it is probable that they do not often do that. If my Florida observation is worth anything to me I must figure on the bees working over a radius of less than a mile; and that if I want my bees to get a full season I must be prepared to move them to stores that are a mile or more away. They will be just playing at gathering honey from scattered blooms here and there to no profit. If I'd move them a mile to where some plant is in full flower, play would quickly become work, and I'd greatly profit.

Bradentown, Fla.

THE COLORS OF WESTERN HONEY

BY M. H. TWEED

A little carelessness in heating honey, changing it from water-white sage to a dark tasteless article, set me thinking about the question of dark and white honey from alfalfa. I talked with a man who is an inspector in one of the counties of southern California, many years in the business, and who, I noticed, took a leading part in the convention at Los Angeles. His idea is that the muddy condition of the Colorado River water used for irrigating is the cause of the dark alfalfa in the Imperial Valley,

and other points where water is taken from that river. I think he is mistaken, for I have seen at Rocky Ford, Col., the whitest of honey from alfalfa, and the water from the Arkansas flowing through the town in the irrigation ditches is almost thick with silt and vegetable matter.

Alfalfa honey from Utah or Colorado is invariably white. Now, why is it that honey from the same blossom in the great alfalfa valleys, Imperial, San Joaquin, and valleys of southern Arizona, is always

dark? I think it is the great heat, the continual sunshine, and the fact that no moisture either as rain or dew reaches the stalk of the growing alfalfa during its whole life; with the thermometer ranging from 90 to 120, without a cloud in sight all day and every day, is it not reasonable to suppose that the heat affects the color?

When I think of white honey my mind wanders over the northern and central states; but when I think of dark honey the scene changes; my mind's eye is on the southern states and the West India islands. There may be something in the soil. When

a man tells me his cantaloupes are from Rocky Ford seed it means nothing to me; but when he says they are grown in Rocky Ford I become interested.

However, I suppose this question is about as hard to settle as the why and wherefore of granulated honey. The man who has had little experience with granulated honey is sure to know all about it; but the man with large experience reaches a point when he feels with a great sense of weariness that he is not sure he knows anything at all about it.

Pittsburg, Pa.

BEES AT THE PANAMA-CALIFORNIA EXPOSITION

BY JOHN W. LOVE

Here were the orchards of Valencia oranges, the lemons, grapefruit, and the other citrus fruits, and rows of persimmons, nectarines, figs, olives—almost everything that could grow in southern California. On an afternoon at the San Diego Exposition I had strolled out under an archway through a formal garden, and suddenly found myself on the model farm, part of the exhibit of the southern California counties. Every agricultural industry of importance seemed to have been recognized, even to the English-walnut business. Surely there ought to be some bees, I thought.

Imperial, Los Angeles, Orange, Riverside, San Bernardino, San Diego, and Ventura counties together occupy the Southern California Building, and united to make one of the most popular features of the Exposition, the out-of-doors exhibit. On this model farm were the model poultry-yards, the model vineyard, and the model garage. I remember with what delight I lounged on the cool cushions in the bungalow and looked out of the open windows to the citrus groves. Indeed, it would be delightful to live in southern California.

Finally I found the bees. Ten hives of them, each with ten frames, made a row of white between the trellises of the vineyard. "Do they attract much attention! Why, so many people walked across this lawn just to get to the bees that we had to put up the fence, but any one who is interested can just step over it." The attendant let me step over.

Bees used for exhibition purposes never gather much honey, of course, and the output of this miniature apiary was not likely to rival the harvest over in Imperial Valley. They pasture mostly on sage on the slopes of the Cabrillo Canyon, the attendant ex-

plained, and on some of the flowers in the gardens of the Exposition.

One of the most popular of the exhibits at the model ranch.

I have had the fever for twenty-five years.

A SMALL BUT PROSPEROUS APIARY

BY JOHN J. LENERT

Twenty-five years ago, while I was looking at some bees owned by a friend, one of the pesky things stung me under the eye. From that time I had the bee fever. A short while after that my father purchased a colony for me, and I have been a small beekeeper ever since.

I have had as many as twenty colonies

and as few as two. My best yield was 300 lbs. of comb honey from eight colonies. My best crop of extracted honey was 750 lbs. from seven colonies. One colony gave me twenty-seven full Langstroth frames in 1913. Last year I took off 200 lbs., but had to feed it all back again in the fall.

Elmwood Place, Ohio.

"WHAT IS IT—NOSEMA APIS, BEE PARALYSIS, OR WHAT?"

BY M. Y. CALCUTT

It is *Nosema apis*. There can be no doubt that the disease that has scourged the bees in this section of the country is nothing else than *Nosema apis*, otherwise known as the Isle of Wight disease. On August 28 I sent samples of both brood and bees to Dr. E. F. Phillips, in charge bee culture investigations, Washington, D. C., and received the following in response:

No disease has been found in any of it. The comb consists of advanced pupae and bees ready to emerge, and these do not seem to be at all affected. No cause for trouble has been found in the adult bees.

E. F. PHILLIPS.

Before I received the above letter from Dr. Phillips I had a long talk with Prof. Trevoe Kincaid, and he informed me that he had discovered the germ that was caus-

ing all the trouble with our bees. After a careful examination with the microscope he had discovered and identified it as *Nosema apis*. The first few bees examined by him did not show the disease, or, to be more exact, he did not discover *Nosema apis*, because he was not looking in the right place. Once he had discovered the bacillus (in the alimentary canal) he had no trouble whatever in finding it thereafter. It would seem from this that Dr. Phillips in some manner must have overlooked *Nosema apis* in the sample that I had forwarded to him.

The sample adult bees were caged from those crawling in front of the hive, and placed in a queen-cage over night. Next morning all were dead.

At the time of writing you I had made up my mind that it was the dreaded Isle of Wight disease. The bees did not act as they do when afflicted with the so-called paralysis. I cannot agree with some that the two diseases are identical. The bees are not swollen and elongated as in paralysis, except in very rare cases. Another strange feature of the disease with us is that it was not followed with dysentery—at least none of the hives examined by us showed it in any degree, although we had cases reported to us.

Now I sincerely trust that Mr. Herrod is wrong in his broad and sweeping statement (page 57, 1914), "Now, any one with the slightest experience of Isle of Wight disease knows that, once stock is attacked, it is doomed." If that statement is true then we shall not have a hive of bees that will survive the winter, for every hive in this section has been more or less afflicted. It is true they are still dying, but very slowly as

compared to what they were in August and September.

In an article the editor says, "The presumption is that the peculiar season—cold, rainy, and wet—has had something to do with it." Let me say that this is the warmest season that we have experienced in the twenty-seven years that we have lived on the Sound. You further say, "We have never heard of *Nosema apis* in this country." Well, let it be hoped that it will never reach you.

It is my belief that we have a couple of hives that are immune to this disease—that is, very few bees have died in these hives. If that is so, then we can restock from them.

What you say regarding the brood as only neglected and starved brood may be so; but scales are left in the cells as in American foul brood. No odor arises, though, from the dead brood.

Seattle, Wash.

WAS IT REAL HONEY-DEW? AN INTERESTING INCIDENT

BY JAMES S. JOHNSON

On the 6th of September I was attracted to my apiary by an unusual roaring of the bees before sunrise. I found them storing honey very rapidly. There were handfuls of bees in front of each entrance; and as the sun came up they worked all the harder. As this was something unusual, there being no flora sufficient for such a flow, I began to wonder what the nectar could be coming from. I made a search, but could not find the source, so I decided that they were getting honey-dew, as I noticed some wasps, flies, and hornets on poplar.

The next morning the same thing occurred again, though even more pronounced than the day before. The bees were coming out of the hives just as though some one had kicked the side of the hive with his foot. I could still see a good many stars, and there was some fog, which made the bees act queerly; but as the light was better and the sun came up they became natural and went about their business with a rush.

In a short time the grass in front of the entrances was covered with laden bees. I caught one of them and pressed its side to make the bee disgorge itself, and the honey was water-white. I decided then that they were not getting honey-dew, and at once began another search. I finally found that they were working on what I call spotted-oak trees. These trees are the rough and scrubby oaks that grow high up on the hills. The bees were getting the nectar from

the base of the buds. They did not work on all the buds, but on certain ones that were on stems about a quarter of an inch in length. I am not even sure that they were buds, but there is a small opening in the end that continuously secretes a clear sweet liquid. I don't know whether to call it nectar or sap, or what. Unless this could be called a blossom I suppose the liquid would hardly be nectar.

My bees are filling their combs full of this stuff; all the queens are laying, and brood-rearing is in rapid progress.

I am undecided as to whether this will make suitable winter stores. If they don't stop storing it the bees will soon have their hives full.

Langnau, Ky., Sept. 13.

[We sent the above very interesting letter to Dr. Phillips, who, in turn, handed it to the Forest Entomologist for attention. Mr. Hopkins' reply follows:

We have referred the specimens to our Specialist in Forest Hymenoptera, Mr. S. A. Rohwer, who states that on certain of the buds of the oaks sent there were galls of one of the gall-making Cynipids, probably referable to *Neuroterus versiculus* (Basset). It is very probable that the sweet liquid that the bees collected is a secretion from this gall as there are a number of Cynipid galls of similar construction which are known to secrete a sweet liquid which attracts insects, especially ants, in great abundance. This is an extremely interesting and unusual record.

A. D. HOPKINS,
Forest Entomologist,

Washington, D. C., Oct. 8.

THE MILKWEED OF BRITISH COLUMBIA

BY W. J. SHEPPARD

One of the best nectar-yielding wild flowers of British Columbia is milkwort, or, as it is locally termed, milkweed, on account of the milklike sap exuded when a portion of the plant is broken or injured. It is not an *Asclepias*, however, but belongs to the periwinkle family, its botanical name being *Apocynum hypericifolium*, so called owing to the similarity of foliage to the hypericum, or rose of Sharon.

The foliage is similar to that of the Rose of Sharon.

It grows from a foot and a half to two feet six inches high, and bears umbels of small bell-shaped flowers, white tinged with pink, which have a strong but fragrant perfume. It commences to bloom about the

It bears umbels of small, bell-shaped flowers.

end of June, and stays in flower for several weeks, being continually visited by the bees. It is a perennial, and grows luxuriantly over nearly all this section of the province.

It seeds freely, the thin hanging pods when fully grown being about three inches long in clusters, reminding one somewhat of miniature dwarf beans. The pods when ripe burst and set free the white-bearded seeds similarly to the fireweed, which is also very abundant here. The honey is light in color, with a pleasant flavor, reminding one of the aroma of the flowers.

Nelson, B. C.

SUNDRY APHORISMS

BY ARTHUR C. MILLER

Don't have any weak colonies. Avoid them or eliminate them. The first is the better and the cheaper way.

So now it is aster honey which is to receive the blame for killing the bees in winter. Guess again. In this locality bees winter well on aster honey, but may die on sugar-syrup stores. That is not a fable. What is the answer? Worn-out bees. "Handling" a lot of sugar syrup or a lot of thin nectar late in the season ("late" means when clusters are contracting) puts

too much labor on the bees, and "ages" them, and that late, particularly with old queens, there are no youngsters coming along to take their place. The solution here is young queens put in about August 20. Mr. Crane, please take notice.

If you must keep bees among the fruit-growers, do not put your hives in the orchards, but only near them—say horse-distance off. There are some two-legged horses which work in orchards who also object to bees at close quarters.

If fruit-growers practice spraying while trees or cover crops are in bloom they should know what will happen. No bees will be kept near them, and the wild bees will be killed off, and I guess it will be a good thing for beekeepers. Oh for sundry reasons! [See article on page 994 by F. R. Beuhne in this issue. The only conclusion we can come to is that sometimes spraying with arsenate of lead while the trees are in bloom kills bees and sometimes it does not. The fact that it does sometimes, always makes the practice dangerous.—Ed.]

Large black ants in this region live in hollow trees, decayed wood, walls of buildings (including chaff hives); and poison which they will take home and eat is the only way to reach them.

No, sir; this is not an easy place to winter bees—averages about as cold as central Ohio, and the changes and extremes are worse.

In considering winter cases, just remember that Quinby said a first-class colony will winter under almost any condition; but it is the second and third grade ones which call for care. Be a "first-class" beekeeper. It pays, and is a lot more fun. I've met some, and ought to know.

If you do not keep record of your apiary you should, and there are just two vital things worth noting—the queen, what she is, and the product of the stock. If you are doing up-to-the-minute, economical beekeeping there will be no other things to note. Isn't possible? Well, it just is. Have three hours to do ten hours' work, one mind to keep track of several important lines, and you will be forced to economical methods.

Piping antics of queens were described long ago, and the attitude and action is the same in the cell as out of it; that is, body flat, chin in, and muscles tense. "Piping" and "quahking" are one and of the same

origin. Avoid it in your honey-producing stocks. [Dr. C. C. Miller will please note that the other Miller agrees with us; but say, you other Miller, why avoid queens that pipe and quahk?—Ed.]

What a relief it is to have an Uncle Sam, leastwise when he turns a Phillips loose on a job! They are tackling the science of bee culture with the best of recording apparatus. I tried it with imperfect tools; and, though I learned much, I also learned that much of my work only suggested what was wanted. Go it, E. F. P.; you'll bust some of our pet notions, and put crimps in the apicultural reputations of some of us, but it will be worth while.

Many farmers do a losing business all their life. They live, but their farms grow steadily poorer. They do not show up so often in the mercantile reports, but they do a losing business nevertheless, and only because the soil cannot demand a settlement do they avoid a "failure." Beekeeping is a rather remarkable branch of agriculture, and has paid some fine profits; but it is fast getting down to brass tacks, and the men who do not run the business economically and far-sightedly will go under as surely and in the same ratio as in the rest of the business world.

When you are planning honey exhibits study color combinations. Patriotism is all right; but the flag is not the best combination of color to put beside honey. The blue against yellow (golden honey) is apt in some lighting to give a very unattractive green cast.

Producing is less than half of the problem, selling is the rest. Just study that.

Interesting, the difference in the size of stocks in warm forenoons and afternoons of April and early May. The forenoons then are a fine time to hunt up and clip queens. This for the novice particularly.

Providence, R. I.

FILTERING HONEY; NO NEED FOR WORRY

BY LUIS RAMIREZ CASABLANCA

In the last issue of *GLEANINGS*, and under the same heading it is said that the workers in the Federal Carbohydrate Laboratory in Washington have passed dark-colored honey through bone char, securing a product as clear as crystal, and that the only drawback to a general employment of this method of filtering is that the cost of bone char is about \$60 a ton. This would not be the real drawback of the method, as the revivification of the bone char would

solve the economic problem, as was long ago shown in the sugar-refineries. The real drawback of the process is that the bone char will absorb both the color and the delicate fragrance of the honey. It is well known that the very strong and offensive smell of the impure alcohol can be entirely eliminated by means of the absorbent bone char or of a good absorbent charcoal. Think what would become of the delicate fragrance of the honey under such energetic

treatment! We should certainly have "a product as clear as crystal," but as insipid, as unsavory as the simple syrup of our drugstores.

The workers in the Federal Carbohydrate Laboratory "looking now for a cheap wood charcoal which will take out the color" must look afterward for a cheap decolorizing charcoal which will not take out the sweet

flavor of that substance collected by the bees from the flowers. But those who know the matter do not believe with the experimenters that they will soon find it. So, Mr. Editor, such honeys as the inferior tropical grades will never compete with the best white clover, sage, and alfalfa now in the market.

Toa Alta, Porto Rico.

AUSTRALIAN NOTES

BY F. R. BEUHNE

DENATURED SUGAR.

When I read GLEANINGS for April 15 I was forcibly reminded of the saying that you must go abroad to get news from home. I have been a beekeeper for thirty years, read all Australian bee-journals that were ever printed, have been connected with beekeepers' associations all along, yet I have never seen denatured sugar or heard or read anything about it or about a request to the general government.

As a matter of fact, there is very little sugar imported, the production of cane sugar being nearly sufficient for Australian consumption. Further, very little sugar indeed is used for bees, and as a rule only at the end of very abnormal seasons for the purpose of supplementing winter stores. In my own experience this has occurred only twice in thirty years.

That in some instances sugar might with advantage be employed for stimulative spring feeding is proved by experiments made during the past three seasons. Our sugar is from cane grown in the northern state of Queensland. There is but one beet-sugar factory (and that in Victoria), and its output is small—about 1000 tons per season. The enterprise is by no means a commercial success.

THE HONEY SEASON IN AUSTRALIA.

Owing to the almost unprecedented drouth experienced over the larger part of this continent during the season of 1914-'15, the total yield of honey is probably less than one-third of a normal crop, while the number of colonies has already declined considerably. The loss of stocks may amount to two-thirds by spring unless the winter, which is now on, proves exceptionally favorable.

The loss of stock is due less to a shortage of nectar than to an entire absence of pollen during the summer months. Breeding entirely ceased during long periods; and as a result colonies dwindled away, even where nectar was available in the blossoms or

combs of honey in the hives. Many beekeepers were unaware of the total stoppage of brood-rearing till it was too late to apply the remedy of a pollen substitute; and some colonies gave out, even after some of the pollen-bearing eucalypts flowered in autumn, the old bees wearing out before enough young ones hatched from newly raised brood. Happily the drouth is now at an end, splendid rains having fallen lately.

In consequence of the small yield and the great demand for Australian honey for army contracts, prices have reached record heights, with 15 cents for extracted in bulk, and 40 cents for beeswax.

BEES AND THE SPRAYING OF FRUIT TREES.

Observations as to the effect on bees of the spraying of fruit-trees with poisonous compounds have now been made during four seasons at the experiment apiary connected with the Government School of Horticulture at Burnley, Victoria, and no harm whatever resulted to the bees or the brood. It is, therefore, very interesting to read, p. 306, April 15, that at least one other institution has arrived at the conclusion that spraying does not necessarily injure bees, even while done when the blossoms are open.

From the report on the Burnley observations, which was published in the *Journal of the Victorian Department of Agriculture*, May, 1914, I extract the following:

At the Burnley apiary the hives are right under the fruit-trees, and at the time of spraying with Bordeaux mixture the ground had not yet been plowed so that the spray fell not only on any fruit-blossoms which were open, but also on the capeweed (a profuse pollen and nectar yielder), then abundantly in bloom. Neither the spraying with Bordeaux mixture nor the subsequent one with arsenate of lead had any effect whatever upon the bees. The colonies developed normally and without any check. There was not at any time dead brood in the hives.

Further, in response to repeatedly published requests, only two cases of alleged poisoning by spraying were reported in four years. One of these the writer investigated on the spot, and found that the bees

had died from starvation—not a drop of honey being present in the combs of the three colonies. In the other case the dead bees sent to the Department for analysis consisted of drones (without a worker bee among them), which had evidently been expelled from the hives owing to a dearth of nectar.

BEE PARALYSIS.

During my work as inspector I am frequently asked what paralysis is. The answer I give is: It is a name given to certain symptoms of distress. Major Shallard's article in *GLEANINGS*, Dec. 15, and your reply, Jan. 15, page 46, show that we have got no further than that yet. What I would call paralysis is the condition described by the editor in his reply to Mr. Shallard; but like symptoms are ascribed to the Isle of Wight disease, otherwise *Microsporidiosis* or *Nosema apis*. But you can find hundreds of colonies with the nosema parasite, and no symptoms; and any number of others with all the symptoms of paralysis but no nosema parasite in the bees. Then there is the petering-out of colo-

nies through a cessation of brood-rearing in summer or autumn, or through shortlivedness caused by a deficiency of the nitrogenous food of the larvæ. This is called the disappearing disease, because as a rule you see few or no dead bees. They die normally. In the one instance the long break in the generations is the cause of extinction; in the other, the failure to live the allotted span of life; and quite often there is a combination of both.

Quite apart from the above there may be colonies in the same apiary that do have paralysis symptoms so the beekeeper calls the whole loss paralysis. If it happens in spring, and the bees show dysentery as a result of bad winter stores, that is also paralysis; and if losses occur without any symptoms it is still paralysis, only the symptoms have changed. It is a convenient name to cover a multitude of shortcomings of nature, and, occasionally, of man. All the same, rabbits and poison are not in it, for it occurs when there is no rabbit-poisoning, and often does not occur where there is. Tooberac, Australia, May 31.

SOME FAMOUS HONEYS OF THE OLD WORLD

BY N. TOURNEUR

That delicious, fragrant, and nutritive matter—honey—is estimated according to the flowers from which the bees extract the sugar existing in the nectaries of the flowers. As certain flowers are more prevalent in particular countries the honey is designated by the name of the country in which it is produced.

The honey from the southern parts of France has held its reputation for generations. That from Narbonne is the most esteemed. It is produced from the flowers of the order of plants termed *Labiatae*, such as rosemary, sage, clary, lavender, mint, pennyroyal, basil, savory, thyme, marjoram, dittany, germander, and many others. All the labiate herbs are very aromatic, which accounts for the peculiar fragrance and flavor of Narbonne honey; and they are free from the principle which imparts to many other honeys an acrid and slightly pungent character. So particular are the Narbonne beekeepers in their choice of the flowers from which their bees collect the rich juices that not only have they the custom of growing choice plants, such as jessamine and mignonnette, around the hives, but at particular seasons the bees are carried in search of the labiate blossoms, the hives being transported by easy jour-

neys from one part of the department to another, and made to rest several days, sometimes weeks, at the bases best calculated to improve the fragrance and quality of the honey.

Narbonne honey is celebrated over all Europe, and the French government gives every facility to foster bee culture throughout the department. Those who have once tasted Narbonne "virgin" honey, the real product, not that which unscrupulous traders sell as such, can never mistake it for any other. There is nothing to be found with the same peculiar fragrance. It is the sublimation of sweet odors and winey sunshine. Perfectly colorless when in its purest state, in warm weather it is like a clear syrup, limpid as the crystal stream. It is quite free from wax, and the common honey expressed from the comb contains very little.

The honey of Spain and Minorca is fine and fragrant, but inferior to that of Narbonne. In Italy there are several fine honeys, but they are not plentiful, though of the coarser kinds there is great abundance. One kind that is gathered by the Milanese, and in Switzerland and throughout the Apennines, is made great use of by Italians. It is produced from the fir, the pine, birch,

L. G. Saugier

C. P. Dadant

H. C. Dadant

L. C. Dadant

DADANT & SONS. SEE EDITORIAL.

and other like trees, and consequently, in addition to being of a dark color, almost black, its taste is almost disagreeably rank and strong; yet with this honey the Italian cook prepares many very delicious dainties.

The honey of England as a whole is inferior to that of the south of Europe, both in hue and taste, and contains much more wax, though in districts where buckwheat is cultivated it is much better, the improvement arising from the flowers of that plant. One does not include in this, of course, certain noted tracts where certain flowers flourish especially.

But the honey of all honeys is found far a-sea. It is not the much-boasted and very inferior honey of Hymettus in Greece, but that obtained in the island of Bourbon, a dependency belonging to France, north of the Mauritius, in the Indian Ocean.

It as far surpasses Narbonne as Narbonne surpasses the other honeys of Europe. Its color is a light green; and owing to the heat of the climate it must be kept, owing to its liquidity, in black wine-bottles or in stone jars. It is not obtained from the domestic bee, but is found in the woods, in hollow trees, where it is deposited in such quantities that from three to four hundred pounds are often taken from the same

trunk. Its extraordinary rare flavor arises from the great variety of aromatic flowers which fill the forests and sparse woodlands of Bourbon. The Mauritius, Rodrigues, and Reunion Islands, though also growing many varied nectars for the bee, do not produce this particular kind of honey—the green honey of Bourbon.

In flavor, a beautiful kind of honey found in Georgia, Asia Minor, comes close to the Bourbon, but it is of a different substance wholly. Deposited by the bees in the clefts of rock, it crystallizes and becomes hard. This honey is not viscid, but is like the white sugar-candy exported from China in its very finest and purest crystalline condition. If kept a long time, it takes on a yellow tinge. It is rich in saccharine, but contains no mucilage, and will, therefore, not ferment spontaneously. In Constantinople it is considered a great rarity, and by the natives of Persia it is considered to be the true nectar, giving sweetness and roundness of flavor to their favorite honeyed sherbet.

At the present time it is worthy of note that one of the finest honeys in Turkey is that produced by the bees from the aromatic labiates so abundant on the now blood-drenched peninsula of Gallipoli.

Rayleigh, Essex, England.

GIVE US SOME LIGHT

BY F. J. LEE

A year ago my daughter had thirteen colonies. When it came time to put the bees in the cellar (concrete walls and floor) for winter her husband wanted to darken the windows; but this being inconvenient, he took a half-depth super, bored a two-inch hole through both sides, and tacked some wire cloth over these holes, put it on a bottom-board, and with a piece of lath stopped the beeway entrance and set the hive on this and put them in the cellar—covers all on.

I was in the cellar several times during the winter, and once in February I could not detect a sound from them. I tapped the side of a hive, and the bees at once "telephoned" "We are all here." I could tell the time on a watch every day without artificial light.

About the first of April the bees began to buzz and try to get out; then the windows were darkened for a couple of weeks before the hives were taken from the cellar.

Every colony was alive and in fine order—very few dead bees on the bottom-boards. Just across the street I had six dead colonies out of eighty-five in a perfectly dark cellar. The young people have twenty hives this fall; and if they winter better than mine this winter I will turn on the light.

Lee Valley, Ont.

[The plan described above is very similar to the Hershiser method of wintering, described in these columns a few years ago. Mr. Hershiser, however, goes further, and has a much larger opening covered with wire cloth below the hive.

We tried the plan in our own cellar, but with rather disastrous results. With the bees in ideal condition, and the temperature and ventilation all that can be desired, the plan gives good success; but if conditions are not just exactly right the few bees that begin buzzing around on the wire cloth trying to get out raise such an uproar that the whole colony is likely to become uneasy. Is it not better to allow any old uneasy bees to get clear away from the hive rather than to have them confined where they can stir up the other bees?

Our correspondent had 85 colonies in his cellar, while the cellar described held only 13. Other things being equal, it is a more difficult matter to maintain an even temperature and quiet wintering when there are, say, 85 colonies in a room than when there are less than 20. Is it not probable that the 13 colonies wintered successfully in spite of the light and confinement rather than *because* of these conditions?—ED.]

MY FIRST YEAR'S EXPERIENCE IN BEE CULTURE

BY D. S. HUNT

First I want to mention a few incidents of my early childhood. When I was a small boy my father was a keeper of bees, but he kept them in box hives, and they were of the hybrid strain. They were very vicious, and possessed of an inclination to attack and sting any object that came too near them. It was hardly possible for me to come within ten feet of their hive without being chased away. During the severe winter of 1894 father lost every colony that he had with the exception of two or three, and he became so discouraged over the loss of the bees that he sold the remaining colonies to a neighbor the following spring for \$1.50 per colony.

Now for my experience:

Last May I purchased a three-frame nucleus and tested golden Italian queen. As soon as they were placed in their new home they immediately began to work very vigorously, and up to July 15 they had increased

so enormously in numbers that I decided I would do some artificial swarming. This was accomplished very nicely by placing four frames of the best brood that the mother hive contained in the newly made hive, together with the mother queen, leaving the original hive the duty of producing them a queen. This they did in due course of time. But a few days after I had divided my bees it began to rain, and kept it up for about two weeks, slowing up brood-rearing and honey-gathering. However, both colonies succeeded in obtaining some honey. In the meantime I placed a super with comb foundation in frames on top of the old colony, and they stored about fifteen pounds of honey in the super.

On August 28 I made an inspection of the two colonies, and, to my astonishment, found that there was no honey in either colony. So I got busy and supplied them with syrup made by dissolving granulated

sugar in water, the ratio being one part sugar to one of water; and I have been giving each colony half a gallon every other day by the Boardman-feeder process. At

present, Sept. 10, they seem to be doing finely in rearing brood, pulling comb, and laying up stores.

Hiawatha, W. Va.

WINTERING ABOVE EMPTY COMBS

BY H. E. CROWTHER

The plan of wintering bees over extra combs of honey or empty combs has been practiced with good results by Messrs. Atwater, Coffin, and others for many years. The main consideration is to have the brood-nest heavy above, and the combs with some honey in them, underneath. This should be done when the bees are not hunting honey too strongly, for in large yards it has been known to start robbing. Also it should be done early enough to prevent loss of any bees in the fall.

A winter like that of 1914 in Idaho emphasizes the necessity of a solidly filled brood-nest, as the continued cold makes it impossible for the bees to move sidewise or downward to the honey. Many colonies starved outright with plenty of honey at the sides of the brood-nest, but out of reach of the cluster. The bees seem to be able to move down the length of the combs well enough; but when the back end of the hive is reached, it is quite a different proposition for them to get around the ends of the frames.

Wintering over empty or partly filled combs applies mostly to colonies run for extracted honey. In case of comb-honey production there are but few extra bodies of honey to be set under; but anyway, the plan is not as badly needed as with colonies run for extracted honey, for the reason that the comb-honey colonies are much heavier, due to the extra crowding that was necessary.

Great care should be used to keep the mice from eating the combs. We reduce the entrance to 5/16 of an inch. We are now using a great many unwired, shallow (six-inch) frames which are not so much of a loss if chewed a little, and are more easily replaced. We have been using them successfully in connection with eight-frame Langstroth bodies for comb honey. The idea is to winter with two of them for each brood-nest—one of them if full enough on top, and the other below. We leave the colony so arranged until stimulation is necessary in the spring. Then the two shallow supers are reversed, the honey going below and the empty combs above. This puts the

bees up to the work of moving and working over the honey, and stimulates brood-rearing equal to or better than any other way I know. If any of the honey is candied, it is worked over, and there is no bother at extracting time, if any happens to be left in the combs. When comb-honey supers are needed, the shallows can be assembled on a few colonies to be extracted later, or used on others for wintering.

This plan was more fully explained by E. F. Atwater, p. 411, May 15, but it did not get the attention it deserved.

The longer we use these shallow extracting-frames the better we like them. In the extracting-yards we have gradually worked into them for several years back, and find them very nicely taking the place of the old deep supers. With them we need but few excluders, and that is an advantage, for I have come more and more to consider excluders quite a hindrance. (I refer to the old-style zinc and wood excluders.) The new wire excluders which we have been trying in yards where we still have a great many of the deep "queen-attracting" combs, seem to be a great improvement. I should think there would be no more demand for the old zinc pattern

Parma, Idaho.

Feeding Coal-oil Flavored Honey

I notice in GLEANINGS a query in regard to feeding bees honey tainted with coal-oil flavor. In 1867 my grocer had some coal-oil-flavored sugar. As I had bought sugar from him at times to feed my bees, he offered me this injured lot cheap. I fed some to a colony with no bad results. Then I took one of my Italian colonies, and put it in an empty hive full of frames. One frame was partly filled for bees to cluster on. I fed the bees about thirty-five pounds of sugar, 2 to 1, and then found the hive nearly full of nice white comb sealed over. The combs were full of syrup, and a good bit of brood was in the hive. This was late in the fall after all honeyflows had stopped. In the following winter this was the only colony I had that did not have dysentery. A good many others died.

The next spring, to satisfy my curiosity, I took a little of the comb left over and tasted it. It had the same coal-oil flavor. After fifty years of experience I would not hesitate a minute to use such coal-oil-flavored syrup.

Heads of Grain from Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

Uncle Raspberry Flow, who lives up in Michigan, and who is always getting into arguments with his wife, says if his queen don't quit quakking all the time he's going to leave the old hive.

The Uniting of Weak Colonies; Why Does the Combination Dwindle?

It is pretty well known and admitted that the uniting of two or more weak colonies for the purpose of making a strong colony is practically useless, and results in no lasting benefit. In a few days the combination colony is left with no larger population than before.

After diligent search of modern authorities I have been surprised to find but slight mention and no explanation of this great loss of bees. It would appear that knowledge of the fact is deemed sufficient, and a knowledge of the reason as of little importance.

Is it not a fact, that a weak colony is always composed of mostly old bees—that is to say, a colony which is weak from natural causes and not from accident or human agency? If such is the case we need not look much further for the cause of rapid dwindling after uniting. A large family of old bees becoming enthused by their sudden increase of force loses many from the excitement, but goes to work vigorously and beyond its strength and age, the effect being to exhaust quickly the vitality of the oldest of the old bees, which then fall by the wayside in greater numbers; whereas, if no uniting had been done the weak colonies would have dragged along quietly for a longer period, only to succumb finally.

As suggested, if "old bees" is the reason (as appears to me entirely logical) then the condition is such that there is no remedy when the uniting is done solely for the purpose of utilizing weak colonies

with the idea of making one good one in place of several poor ones, and the futility of the plan is self-evident. There is, however, some satisfaction in knowing why a thing succeeds or fails.

New Jersey.

B. KEEP.

[It sometimes happens that, when it seems desirable to unite, the bees of the weak colony are old, weak, worn-out ones, just as you say. This condition may apply in the spring as well as in the fall. Uniting in either case will not result in much good, and therefore your explanation is quite plausible, and possibly may be the true one.]

Very often, however, colonies are united in the same apiary, made up of young and vigorous bees; but the loss is occasioned by these young bees going back to their old stands and becoming lost, or else they find their way in near-by hives. Uniting, however, can generally be practiced to very good advantage, if the bees are not too old, by uniting two colonies side by side, or taking the nuclei from an outyard and uniting them after they are brought home, as explained in the reply to Mr. Stratton, in this department. In either case, if the bees are not too old, a fairly good colony will be formed, in good shape for winter. We have been doing considerable of this outyard uniting and neighbor-hive uniting, and the results have been very satisfactory this fall. Moreover, there has been no diminution of the strength of the united colony as there has been sometimes.—Ed.]

Uniting and Feeding; Is It Too Late?

I should be glad to have your advice as to the relative advantages of uniting or feeding weak colonies at this season in this section. Owing to a cold spell when the asters were in bloom, or from some other cause, brood-rearing stopped early, and bees are short of winter stores. Many beekeepers are facing the alternative of feeding or doubling up, and, no doubt, will be interested in your answer.

I will say that the aster is our main dependence for winter supplies, and we have no trouble in wintering on summer stands.

C. L. STRATTON.

East Chattanooga, Tenn., Nov. 12.

[You speak of the alternative of uniting or feeding. We know of no reason why you should not do both. If the colony is weak it ought to be united; and then if it has insufficient stores the combination should be fed. Of course there are various ways of uniting. To pick up weak nuclei from several different places in an apiary, and combine them together in one place, is not satisfactory, on account of the many returning bees. The usual plan is to take two colonies side by side. Remove one hive, and then place the other hive in the space between the other two. Put the two colonies together, preferably on a cool morning or evening, and then let them gradually unite when it warms up the next day. If there is no choice of queens, let the bees make their own. Of course if one queen is better than another the operator should kill the inferior one and unite.]

It sometimes happens that there will be a medium-sized colony and a weak one side by side. Remove the hive containing the weak one entirely, and put the weak one with the strong one or the medium-sized one, and the uniting will be accomplished very satisfactorily. When colonies are at outyards, and it is expected to move the outyard to the home yard for wintering, the uniting can be very easily accomplished by placing two, three, or four weak nuclei together and uniting at the new location.

In the matter of feeding, if the weather has turned so that it is cool during the day, especially cool nights, the syrup should be given hot—about two

parts sugar to one of water by measure or weight. But the syrup should be thoroughly stirred so that it will be all dissolved before giving to the bees. The aster stores would do no harm in any case, providing the syrup were stored on top of the aster. Of course it is always desirable to do the uniting early in the season and feeding early if possible. But even when early feeding is practiced, a final feed sometimes becomes necessary if brood-rearing sets in between the time of feeding and the final packing in the fall.—ED.]

Compensation on a Contingent Basis; Number of Colonies Needed per Acre in Citrus-groves to Pollinate the Blossoms

Mr. Root:—I should be grateful for your opinion on the following. Mr. A owns some hundreds of acres of citrus and deciduous orchards in two groups sixty miles apart. He wishes to develop apiaries for the primary purpose of pollination, but with a view to having them profitable in themselves. These are to be developed from a beginning of thirty colonies to take care of pollination as the young trees come into bearing. B has been secured to take complete charge of this apiary development, and control policies and methods of development. A pays B \$1.00 a year per colony (spring count) for management, \$1.00 per colony increase, and 50 cts. per hour for actual labor in apiary and office. A, of course, pays all expenses of labor, equipment, etc. If this arrangement is unfair to either party, please state what changes you would suggest, and also any better basis for agreement.

Please inform me as to the ratio of colonies of bees to acres of deciduous orchards to secure thorough pollination to secure the maximum honey yield.
Glenn, Cal., Oct. 19. PAUL J. DAVIS.

[It is rather difficult to give a detailed answer to a proposition of this sort. Perhaps the plan proposed of compensating B is fair; but a surer and a better way would be to pay him so much a day for the time actually employed. These contingent schemes of compensating an employee sometimes work out well, but more often they cause dissatisfaction, not to say quarrels, between the parties.]

We usually estimate about one colony to the acre for apple-orchards as being sufficient to pollinate when weather conditions are at all favorable. When the weather is bad during the time of bloom, more colonies are needed, as practically all the work of mingling the pollen may have to be done inside of an hour. In citrus groves, one-fifth or perhaps one-tenth of the number of bees required in an apple-orchard would be sufficient. The reason of this is, because the weather conditions are more favorable in orange, lemon, and grapefruit groves, and because, further, the blossoms do not all come out at one time. This enables a smaller number of bees to do the work because the time for doing the work is greatly extended.—ED.]

How to Get in the Game

A correspondent says that he is investigating the bee business with a view of starting an apiary, and he asks how much land is needed for five or six hundred colonies, and what would be most suitable.

I have written him that unless he is experienced in the bee business it would be a great mistake to start with as many colonies as he suggests. One must "grow" into the business, so to speak, so that the errors made while learning will not be so expensive. I began with four colonies, and was five years building up to one hundred stands. The mismanagement and mistakes made with those four colonies would cost me a pile of money if I should do now what I did in the beginning, and would utterly discourage a beginner.

One acre of land would be sufficient for yarding 600 or more colonies; but in the Mississippi Valley states it is seldom that more than 100 colonies are kept in any one place. An apiarist running a great number of colonies, has them scattered through several yards so as not to overstock any one locality. In selecting a site for an apiary I should prefer it near some habitation on a bluff or hill land overlooking a wide area of river bottom or swamp. Such a location has an abundance of honey-yielding flora, and does not suffer from drouth.

Washington, Ind.

S. H. BURTON.

How Fast Does It Go?

How many revolutions per minute should a honey-extractor make?

Nelson, B. C.

GEORGE FLEMING.

[There is no definite speed that can be given as proper for a honey-extractor, for it depends upon the condition of the comb. The reel should turn as fast as it is possible to turn it without having some of the combs broken by the centrifugal force. The older the combs and the tougher they are by reason of the layer of cocoons in case of combs used for brood-rearing, the faster the reel can turn without danger of comb-breakage.]

New combs which are much more fragile must be turned very slowly until the bulk of the honey is out of one side, then the pockets reversed and the reel again turned slowly until the bulk of the honey is out of the other side. There is little danger, then, in speeding up to throw out the rest of the honey on the second side. The pockets should finally be reversed to the first side, and the reel again speeded up to throw out the rest of the honey on that side. With the older, tougher combs, this added precaution is not necessary.

An eight-frame power extractor should have a reel speed of 250 revolutions per minute on the average. The smaller extractors require a greater speed.—ED.]

Virginia Bees Almost Down and Out

My bees gathered more honey in the spring than for five years before. They filled up the supers from locust bloom and white clover, and until the middle of July did very well. Since that time they have not made their own living.

We had so much rainy weather the latter part of August and early September that the bees got no benefit from the fall flowers. There were only two or three days in September that they worked on aster—our only fall flow here. As soon as the weather cleared, a frost killed everything.

I took two supers of honey off some of my hives, and found some of the colonies on the point of starvation. I have not a single colony with enough stores to carry it through the winter without feeding.

Ninety per cent of the bees in this section will die if they are not fed. June and July swarms made no honey at all, and it is the first time in several years that I failed to see some brood-rearing. If they can be wintered at all, bees will be very weak in spring. Several have lost colonies already.

Roanoke, Va., Nov. 12.

HENRY S. BOHON.

Jackknife for Scraping Sections

I use a large-sized jack-knife kept very sharp for scraping sections. I have tried caseknives and butcher-knives, both dull and sharp, but like the jack-knife best. I have never tried sandpaper.

Aitkin, Minn.

WILLIAM CRAIG.

A Correction

In the Nov. 1st issue, page 894, the description of my wheelbarrow should have given the length as 6 feet instead of 6 inches.

OUR HOMES

Editor

And God said, Let there be light: and there was light.—GEN. 1:3.

And God saw the light, that it was good; and God divided the light from the darkness.—GEN. 1:4.

And God made two great lights; the greater light to rule the day, and the lesser light to rule the night: he made the stars also.—GEN. 1:16.

And God set them in the firmament of the heaven to give light upon the earth.—GEN. 1:17.

A few days ago a man who has been for many years editor of our *Medina Gazette*, and a man much loved and respected in quite a region round about Medina, said to me something like this:

"Mr. Root, some day I am coming down to see you to learn, if I can, why it is that you, a man of *seventy-five*, should seem to be right in the prime of life, when I at *forty-five* seem to be just about played out."

I knew he had sold his publication and given up the splendid work he had been doing for years; and I had also been told that it was on account of ill health; and I have been planning to see what helpful advice I can give him. By the way, it occurs to me he said something about my "secret" of deferring old age. God knows I have no secret in regard to health or any thing else in this whole wide world, that I am not willing to give freely to any or all.

I think I have lately been showing briefly, not only here on these pages, but by word of mouth, that the great secret, if there is any, is outdoor air and God's bright sunshine. Before going further let me give you one of the kind letters that keep coming day by day. I suspect it was written by a woman; but as the writer does not want name given we cannot very well find out, and it does not matter much, any way. Now listen and be ready for a big hearty amen when you get through.

"SUNSHINE" AS WELL AS "FRESH AIR"—A NEW (?) DISCOVERY.

I have been reading your Home talks for several years with great interest; and after reading your Home talk on fresh air to breathe, for both humans and the little chicks, I was moved to write to you and tell you of my discovery, and that is—sunshine for the babies. We have a little one in our home, just three months old; and since the time he was about two weeks old he has had his sun bath daily—not with the sun shining on his clothing, but on his bare skin. He has never been sick, and has made a steady gain of 2½ lbs. a month, which is extraordinary so far as I can find out.

Well, you ought to see how happy the little fellow is when lying naked in the sunshine. He laughs and crows and kicks, and shows in every way he can his extreme delight. His skin is as brown as a Mexican, and his flesh as firm as a working-man's. He sleeps all night, and has never given us any trouble in the way babies usually do, and we think the sunshine does it.

I am not writing this for publication. I want to ask you just to take up the subject of sunshine, and give us a talk on that, as you have so well done on the subject of pure air. Think of it! all the little calves, colts, lambs, and pigs can enjoy the sunshine while the poor babies are deprived of it. You have, no doubt, noticed how the little animals enjoy the sunshine; and do you believe one of them could be raised without it, or, when exposed to it, be covered up with blankets? They would be as worthless as plants raised in the shade. I could also mention that sunshine is the best mold and germ killer, and many other points. Sunshine for the babies, and grown folks too—not on the clothing but on the bare skin.

Fillmore, Cal., March 22.

W. C. G.

God bless the babies. (See "The right to be born sober," p. 867, Oct. 15.) If they have not a right to everything good in this world, who has a right? It rejoices my heart to see that, day by day, we are giving babies more thought and time than ever before. By the way, I wish my good friend would send us a picture of that "sunshine baby." The letter only emphasizes and calls attention again to what I have long had in mind. Outdoor air and sunshine are God's two great remedies. I would add, also, plenty of pure water—the purest that can be had. As for myself, I am quite sure that boiled rain water is best for me. Of course, I want it moderately cold. Next I would say good wholesome food—not too great a variety; nothing at all later than, say, four or five in the afternoon.* I think the above advice is needed, especially by elderly people; and after the things mentioned we want plenty of good sleep† uninterrupted

* In reading over the above after it was in type, it occurs to me I have not put sufficient emphasis on sleep, especially if I preach what I practice instead of "practicing what I preach." When I am doing severe office work, say several hours in the forenoon, or even hard work in the garden, I often find myself "used up." Then I go and take a nap. When things are crowding I have two naps a day, and in extreme cases as many as three. Just of late I have been called a good deal to give talks at Sunday-school conventions, etc.; and I have tried to get over home and get down into my "sun parlor" and get twenty or thirty minutes of sleep before I give my talk. I often tell Mrs. Root something like this: "Sue, I am to talk before a convention at two o'clock. I am now going to take a nap, and you must be sure to call me at ten minutes before two." With my little electric I can easily get up to the church in ten minutes. Then I will be ready to do my best.

Yesterday, Oct. 17, I was called to address a Sunday-school convention; but there was a crowded church, and several speakers were before me. So I had to sit and wait an hour and a half before I was called to speak. The consequence was, I was so tired of sitting still that I lost about half of my vim and enthusiasm. Perhaps it is not possible for every person to recuperate as I do by a little sleep; but to me the sleep is like recharging a "storage battery."

† Of course the above refers to grown-up or elderly people. Nobody would think of advising that a baby, or even children or young people, should conform to the habits of full-grown people. Babies must be fed like little chickens, at short

by disturbance in the digestive apparatus. Let the last meal of the day be early in the afternoon, and let it be something easy of digestion—fruit, for instance. Nice luscious peaches have been my last meal for several weeks past; and with the fruit, as I have several times mentioned, I have a little nice cheese, which I prefer to be old and well ripened. But unless I eat this sparingly there is a cheesy taste left in my mouth when I wake up in the morning. I have also mentioned cottage cheese. The “sanatogen” which we see advertised has, perhaps, done *some* good in calling our attention to the wholesomeness of cottage cheese. Well, the cottage cheese digests perfectly, and leaves no bad taste in my mouth, and is, I feel sure, one of the best and most wholesome foods in the world for babies when they are old enough to eat it, and for old people, and for anybody, in fact. Cottage cheese is now on the market for only 10 cts. per lb., or less than half the price of the regular cheese.

There is one thing more to be added to the sunshine, fresh air, and food and drink, and that is *exercise*. Children will, as a rule, take the proper amount of exercise if they have a chance; and let us each and all, *for Heaven's sake*, provide a place where they can have good air and sunshine. A few days ago Mrs. Root asked me if I heard the shouting and laughing over on the hillside back of our house. What do you suppose I saw when I went out there? Four little girls—Helen, Jean, Katherine, and Elizabeth, were riding downhill in two little wagons. As they have not learned to steer very well, the wagon was usually upset by the time they reached the bottom of the little hill; and then there was a scrambling and kicking of legs and arms (pretty much bare) in the sunshine on that south hillside. As it is covered with soft grass they did not seem to get hurt.

One reason why I so much enjoy going down to Florida is because down there I can dispense with a large part of my clothing and take vigorous exercise right out in the sun. A few years ago a lot of my friends laughed at me because of my fur cap. I have not only dispensed with that fur cap, but I have been getting lighter and lighter caps for the past two years; and when the weather is warm, and most people are complaining of the hot day, I just feel real happy without any cap at all;

intervals. I think Mrs. Root used to give her babies some warm milk one or two times during the night. Of course they had less as they grew older, and the five little Roots are all alive—yes, very much alive and kicking around, even if some of them are over fifty.

and I work in the garden bareheaded hour after hour. I have found it an excellent plan, also, to get off my coat and vest; and with the ventilated shoes that I have described I just feel fine; and when off alone I can sing praises to God for having given me 76 years of life already. Much has been said about the health of the colored children. Many of them would go next to naked if nobody complained. Down in Cuba I saw children *going to school* without a rag of any sort on them—bare hands, bare head, and everything bare from head to foot, both boys and girls. I think there was a protest being made at the time I was there. Just think of the indignity the northern-raised schoolma'am would suffer on being obliged to teach school where boys and girls are sent to learn their A B C's, without clothing! Very likely all of that is done away with by this time; but is it not true, dear friends, that the tough and hardy endurance of the colored race is largely due to the abundance of outdoor air and sunshine on almost every portion of their bodies?

When I spent a part of one *summer* in Florida one of the things I greatly enjoyed was working in the garden in my night-dress. If you have never tried it you can scarcely imagine the delightful sensation of a cooling breeze right on the naked body when you have had exercise enough to feel a little hot and sweaty. The modern style of dress for young girls and women, even though it is objectionable, and may sometimes have been carried to extremes, is, I honestly believe, going to give better health to the young mothers or to the growing girls who expect to be mothers in due time. May God help us to hold fast to the sensible, reasonable freaks of fashion, and to reject and protest against everything that is unhealthful and unreasonable.

I have not said very much about physical exercise in the above, although I have several times alluded to the big advertisements in the line of athletic schools. There are many such schools being started just now which ought to teach people by experience, and sometimes *sad* experience, to beware of some of these pickpockets. Beware of anything or of anybody who first wants \$50 or \$25 for a course of athletics; and if you do not “bite” the first time, as the weeks go by they keep coming down a little. When you are finally offered the same thing for \$5 or even \$3, you may think you are in luck; but you will find what you have paid for is something already taught in our schools or in our health publications. If it is true, however, that

you go through with your athletics just because the course has cost you \$5 or \$10 when you would not otherwise, it may not be so *very* bad an investment after all. Now, then, whether I am here in Medina with a comfortably fitted-up bathroom, or down in Florida in our comparatively cheap cottage, I bathe all over every day of my life; but before taking my bath I swing my arms and exercise my legs and rub my body all over until I am so well warmed up that I can take a bath without wanting it warmed, even if the temperature of the room should be down to 60 or lower. When the weather is cool I prefer to have the water warmed by some means up to 60 or 70. After bathing I use for a towel a good large piece of cheap cotton cloth, something perhaps half the size of a bed sheet. I take hold of the opposite corners and draw it back and forth across my back, and "see-saw" across my chest, around my legs, over my head, until every part of my body is warmed up by the friction, and by rubbing around my neck, my head, and about my ears, as I have explained before. If I were going to have another bath-room I would have a bay-window toward the south or southeast or both; and when we have long days I could take my bath and get a sun bath at the same time; for I feel perfectly sure that there is *nothing better in the world*, for an ailing person, than to let the sun strike directly on every portion of the body.

You know I am studying and enjoying seeing plants grow, perhaps as I never did before; and before I got this letter I was coming to the conclusion that sunlight is one of the greatest and most important things for plant growth. We have a row of evergreens for a windbreak on one side of our garden. I thought at first the roots of the evergreens had spoiled that side of our garden. No matter how much manure or fertilizer I applied, the plants would not grow there. Melons will not thrive and ripen, because they do not get the afternoon sunshine. All kinds of plants and flowers up near a high fence or building turn their heads away from the building. Sunflowers especially follow the sun. They turn around in the night so they can see the sun when it comes up. Then they look at him, as a rule, in the face all day long, and at night they are peeping and stretching their necks to get the last glimpse of his declining face. Nothing grows around a big thrifty tree. It is not alone a lack of moisture because the roots of the tree take it, for this year there was moisture to spare from spring till fall; but nothing thrives in the shade of a

tree—that is, almost nothing. We have a few plants, it is true, like the ferns and mosses, that cannot bear the full light of the noonday sun, but they are an exception. The same thing applies to animals. See the chickens, how they flop their wings and run in pure enjoyment and delight when they are let loose in the sunshine. Every little while I see somebody trying to raise chickens indoors, sometimes by artificial heat, when the chicks would be a *thousand times* better off right outdoors; and the same thing is true with humanity. Babies and old people must have sunlight as well as fresh air. I suspect one reason why so many people get well by going to Florida is because there is more sunshine there than almost anywhere else. Some years ago the editor of a paper in Tampa said his periodical would be sent free of charge every day the sun did not shine there. Last winter, however, was such an exception that, if he keeps it up, he will have a tough job on his hands. People have mistaken notions about sunshine. Nobody supposes you can stand it to sit right down in the hot sun. Get out and work at something. Stir around and "do good" until the sweat drops from the end of your nose; then you will forget all about its being a hot day, and throw off your useless under-clothing and get a sun bath, as our good friend expressed it about the babies. Then you can thank God for fresh air and for the sunshine, even if the mercury is up to 100 in the shade.

May God bless this message; and may it be the means of giving health and happiness to a crowd of people; and when you have gotten both health and happiness, do not forget to thank God who gives us the sunlight, and—"God saw the light, that *it was good*."

BEE CULTURE IN SOUTHWEST FLORIDA.

On page 685, August 1, our good friend F. M. Baldwin gives us an article which I feared was giving almost too bright a prospect for starting bee culture in Florida, after taking into consideration seasons in general. Below is a report for 1915 from our good friend Ault, who last season managed to get pretty close to 200 lbs. per colony. You will notice by reading the article carefully that while some locations give a fair yield, another apiary only a few miles away furnished almost no surplus.

THE HONEY CROP IN SOUTH FLORIDA.

While I am not in position to give definite statistics of the honey crop in this section of Florida I do not think it will reach above 20 per cent normal. As is common in "off" seasons, the honey flow has varied greatly in different localities. Mr.

Felts, of Palmo Sola, reports a much better yield than last year. With this exception all the reports reaching me have been unfavorable, and I do not think the average yield will reach over 40 per cent of last season.

Some of my apiaries have yielded an average of 40 lbs. per colony; and one apiary averaged 75 lbs. One gave an average of 10 lbs., and my home apiary of 40 colonies has yielded no surplus. In most of my apiaries the bees are well provisioned and strong; and I hope, after the fall flow, to make a better report.

People often remark to me that the bees must be "making" a lot of honey, and then they will tell of seeing bees working on some flower. At the same time, the bees were probably consuming more honey than they were gathering.

The honey-flow from black mangrove was short, though the bloom was profuse.

Coming in an unusually dry time the quality of the mangrove honey was the finest I have yet taken.

June 30 I visited my bees on Anna Maria Key, going by launch from the town of Cortez.

For some reason unknown to me the mangrove on Anna Maria was just coming into bloom, while across the channel to the east on the mainland, and also on the island of Pereka, it was in full bloom.

Coming home in the afternoon I was surprised to see large numbers of honey-laden bees crossing the channel in the direction of my apiary. Some of the bees were crossing diagonally, where the distance across the water was not less than $1\frac{1}{2}$ miles. We saw only the laden bees flying toward the hives. I suppose the outgoing bees flew higher and more swiftly, and so we did not see them.

FETERITA IN FLORIDA.

The first heads of my feterita were heavy with seed, but the heads that put out later had but little grain. The plant produces a quantity of good feed; and where I cut the old growth the sprouts from the roots are four feet high, and growing fast. The worst drawback to its cultivation here are the birds, which come by the hundreds and devour it. The blackbirds and quail are the worst.

My feterita has attracted a great deal of attention, and many have expressed a desire for seed. We have recently been blessed with some showers, and farmers are getting busy.

LATER.—HOW FAR MAY BEES FLY ACROSS THE WATER?

A few days ago I wrote you enclosing a brief statement of conditions here, and told of the flight of bees across the channel separating Anna Maria Key on the one side and Palma Sola peninsula and Cortez Point on the other side, with the island of Pereka between. To make sure I was well within bounds I stated that some of the bees flew $1\frac{1}{2}$ miles across the channel. Yesterday we again made the trip from Cortez to my apiary on Anna Maria, $3\frac{1}{2}$ miles distant. On inquiry I found that the distance across the channel to the main land was about two miles. Diagonally across the channel to the island of Pereka and to Cortez Point, from which, at the time stated, large numbers of home-coming bees were crossing, the distance is all of $2\frac{1}{2}$ miles. The bees were flying slowly, and close to the water.

This was of interest to me as showing the distance bees fly across water when conditions are favorable.

ARTHUR E. AULT.

Bradentown, Fla., Sept. 19.

HIGH-PRESSURE GARDENING

THE HELIANTHUS AND THE JERUSALEM ARTICHOKE.

The friends may recall that last year I grew four or five hills of the helianthus, and pronounced it excellent food. I supposed, however, that I had dug up all the tubers before going away; and I mentioned that one of the objections was that they were so small it was troublesome to harvest them, especially in clay soil. Well, when we got back to our Medina home, about the first of May, there was a wilderness of helianti a foot high or more, right where I dug them last year. I let them grow, and now we have a great crop. At one end of the helianthus-patch there were some stalks that looked a little different from the others. In fact, they grew six or eight feet high. I did not know any artichokes were planted there; but these grew three or four great big stalks, and produced regular old-fashioned artichokes. Now, we have cooked both the helianthus and the artichokes. We just boiled and served them as we would serve creamed potatoes, and, once more, I cannot see any difference in taste; but the artichokes are so much less trouble to prepare for the table we greatly prefer them. Just one thing more:

Both artichokes and the helianti produce a great lot of green tops before anything else. Both winter over, and are ready to start the first thing in the spring. If this young and tender foliage will be eaten by stock, why is it not profitable to grow for feed? I am sorry I did not think to offer it to the cows, pigs, and chickens. If the tops prove valuable, the helianthus might be preferable, because the small tubers will go so much further in planting. If artichokes are really a substitute for potatoes, or I might almost say *better* than potatoes, I do not see why they have been so long neglected as an article of food.

The letter below touches on the whole thing. Very likely locality *will* have something to do with it.

Mr. A. I. Root:—I wonder if the old Jerusalem artichoke and helianti are not one and the same vegetable. When I was a boy, 60 years ago, we lived in the south part of Erie County, Pa. One of our neighbors grew artichokes quite extensively, and cooked and ate them as we did Irish potatoes. They grew as large as other potatoes, and yielded fully as well. In the 80's I lived on a city lot in St. Joseph, Mo., and planted artichokes in my back yard, and they grew fine, being very productive, and made a splendid salad; but I did not like them cooked. In 1904 I moved to Madison County, Mo. There I got some artichokes from a neighbor. They

did not grow larger than peanuts, and were no good. Was it location or a different variety?

Boicourt, Kan. D. C. ANDERSON.

SWEET CLOVER IN NORTH DAKOTA.

In looking over the agricultural journals of late I have several times said to the men of our firm, "Here is something about sweet clover that breaks the record of anything heretofore." Well, just now from that new monthly, *The National Alfalfa Journal*, I clip the following. Read it and see what you think of it.

A NORTH DAKOTA SWEET CLOVER SUCCESS; HOW SWEET CLOVER HAS BEEN MADE TO CHANGE THE VIRGIN SOIL INTO BIG AMERICAN DOLLARS—FEEDING AND MARKETING THE CROP.

In the first place, this sweet-clover plant is not a new plant to the old timers in this county. We have seen it grow in yards around buildings, on the roadsides and railroad grades for the last twenty years. All we know is what people from the middle states told us, and they condemned it as a pestiferous weed that eventually ruins the farms. Many cut it while in blossom on the roadsides and burned it in order to destroy the horrible stuff, and still there would be sweet clover the following year.

Stock would not or could not eat the "stuff," hence absolutely worthless, so these Illinois farmers told us, and they certainly knew. Many of us contended that inasmuch as it looked like alfalfa it might contain the same fertilizing properties, and perhaps stock would eat it if they once got the taste of it.

Personally I felt that if the plant prospered so well along the roadside and wherever it could get a foothold in a gravel bank, if it could be utilized as a forage crop the question of diversified farming in North Dakota would be solved forever. I cut some of the green weed and took it with me to my farm to see if the cattle or hogs would eat it. That was in the summer of 1913. I found that, as a matter of fact, both hogs and cattle did eat it after being locked up for half a day without anything else to eat. I tried several times and concluded that the hogs at least would take to it like a duck to water.

I had wondered to myself where I could obtain some seed for a trial. I asked the agricultural experts, but none seemed to know just where. One day, Mr. Burns, the Eddy County man, informed me that he had learned that sweet-clover seed could be obtained in Kansas, and that he would arrange with the agricultural station in that state. However, before his answer came I learned from an article in *Successful Farming*, one of the best agricultural papers in the West, published at Des Moines, Iowa, where I could obtain seed, and further learned from this paper that many had raised the sweet clover for a number of years, and all praised it, both as a fertilizer and for pasture and hay for all kinds of stock, being almost equal to alfalfa. I also learned that the Agricultural Department at Washington has issued bulletin No. 485—which can be had for the asking—and I sent for it and read it several times until I knew all the instructions by heart.

After being fully convinced that sweet clover is just the very plant that we need on our fertility-depleted fields, I purchased white-blossom sweet-clover seed to sow twenty acres, prepared the soil according to directions as sent out in Bulletin 485, and seeded twenty acres at the rate of fifteen pounds to the acre, May 10, 1914.

In order to outline the results fairly I feel it necessary to mention more particularly the result as a hog pasture than for any other purpose. We

had two small hog pastures containing one and one-half acres each, or three acres in all, that had been seeded to oats and barley for several years previous and hogged down. Everything had been eaten to the ground—grain, straw, and all. We disked these patches twice, and seeded 15 pounds of hulled seed to the acre, and left the hogs on it from the day it was seeded.

In spite of the fact that some fifty large hogs and as many or more pigs tramped over this ground, picking what young plants had started to grow, they failed to destroy the roots, as it kept on growing all summer. I seeded fifteen pounds to the acre on the rest, or seventeen acres. Seven acres of this was seeded on alfalfa ground that was seeded too thin to make a crop of value. On two acres I seeded barley as a nurse crop. Nine acres of the plat was on corn stubble. We disked it two times, and seeded as before. Two acres were spring-plowed and packed with a Dunham packer. Both the corn stubble and spring plowing were seeded without a nurse crop.

On June 27 we had this plat of 17 acres fenced in and turned the hogs on it—over 50 full grown and about one hundred pigs. The sweet clover was then eight to ten inches high. On July 8 we concluded that the hogs could not eat it down fast enough, and we cut all but the spring plowing and barley for hay. We gathered fourteen loads; but there was some pigeon grass and some alfalfa along with the sweet-clover hay.

The hogs continued to eat it, but could not keep it down altogether. We fed them not to exceed a pound of barley a day. About the middle of July we turned in nine calves. They went at it as though they had been trained. Still the clover grew too fast, and we turned in fifteen horses, among them seven mares with colts. About the first of August the hogs had increased to over 200, but still this 20 acres seemed to supply all the nourishment that these 229 head needed—excepting, of course, what we fed the hogs—and continued to feed them all until the middle of September, when we removed most of the horses. About the first of October we left only the weaned colts, calves, and the hogs, and they continued to feed on the clover until freezing time. About the middle of October we fenced in 26 acres of corn for the hogs, but still they turned to the sweet clover for green food, and even went so far as to pull it up by the roots and eat it, roots and all.

I will say in addition that I never saw stock do so well on any pasture in North Dakota. I have never raised as fine a bunch of calves during my thirty-five years' residence, and have never gained such profit on hogs as I did on this 20-acre plat of white sweet clover. I may add that I shall seed 50 acres of corn stubble to sweet clover this spring for additional hog pasture, as I have 135 or more sows which will have pigs in the spring.

In addition to my experience with sweet clover there are eight others in this vicinity who have gone "wild" and seeded from one to three bushels; but this has mostly been seeded with a nurse crop. I also seeded about one acre in a barley-field, and it looked very good after the barley was taken off, and will no doubt make a heavy stand the coming year.

Some have asked if sweet clover should be preferred to alfalfa. So far as I am able to judge I would answer yes and no. It depends entirely upon your local conditions.—P. M. Mattson.

We think it will pay our friends who are interested in sweet clover and alfalfa to subscribe for this alfalfa journal, published at Sioux Falls, S. D., at only 50 cts. a year.

TEMPERANCE

HOW PROHIBITION "STOPPED BUILDING."

TUCSON, Arizona, Oct. 20.—When Arizona "went dry" it was asserted that the result in this city would be "no more building;" that the 32 vacant saloon buildings would be such a drug on the market that not another structure would be erected in the city in a long time. Now, according to the report of the city building inspector, 1915 will show the biggest building record in the city's history, the building cost falling, all told, not very much below half a million dollars; whereas the record of 1914, the last license year, fell below \$400,000, and 1913 just exceeded \$300,000. The emptiness of the "32 empty saloon buildings" vanished like the dew before the necessities of legitimate business.—*The Vindicator*.

PROHIBITION IN ARIZONA.

Bro. Amos:—In regard to whisky and the effect of its being "cut out" here: It has caused much trouble for some of the officers to watch the "bootleggers," as they run their autos over the line in New Mexico, and smuggle it in. But the law is so strict that they will get tired of it soon. It seems as though "old Ohio" ought to be as much civilized as Arizona.

Pima, Ariz., Oct. 29.

J. H. Root.

My good brother, Ohio is pretty well "civilized," except the great cities—Cincinnati, for instance. They are, however, well along in the A B C class, and will surely "get there" if we "faint not." See the following from Wayne B. Wheeler:

OHIO ON THE "UPGRADE" STILL.

Last Tuesday's election in Ohio is another evidence of the fact that the progress of a righteous cause is absolutely irresistible. Twenty-two years ago, when the League work started in Ohio, if we made any mention of the possibility of statewide prohibition it was ridiculed. It was a struggle to secure even local option for the smallest units. The sentiment gradually grew until the people secured local-option laws for all the units of government up to the county. The high tide under county option and local-option laws was 63 dry counties. The vision of the people continued to broaden, and their convictions continued to deepen until on the statewide vote 70 counties went into the dry column.

In this last election the majority of 84,000 against prohibition was reduced to approximately 40,000. Seventy-four counties of the eighty-eight voted for statewide prohibition (unofficial returns). This splendid result was accomplished in spite of the fact that it was an off year in voting. The city vote was heavy because municipal officers were elected, and the rural vote light because no state officers were elected.

There is nothing discouraging in the result; on the other hand, it is positive proof that, with steady fighting, more education, better organization, and with half as much gain in the next contest, victory is sure.

W. B. WHEELER,

Attorney for Anti-saloon of America.

Columbus, O., Nov. 3.

THE DAVIS LAW DECIDED CONSTITUTIONAL.

We clip the following from the *Florida Times-Union*:

Supreme Court, by a close vote, 3 to 2, declares Davis Package Law constitutional. Opinion filed early yesterday afternoon in habeas corpus proceedings brought to test validity of Davis Package Law.

Decision had been eagerly awaited for weeks throughout the state. Sections 1 and 7 of the law were attacked by counsel for liquor-dealers in effort to have the law declared unconstitutional. Law was considered exceedingly stringent; Chief Justice Taylor and Justice Ellis rendered dissenting opinions.

See our recent back numbers for particulars in regard to Davis law.

"BOOZE" ADVERTISING; CAN'T SELL PAPERS HAVING SUCH IN GEORGIA.

We clip the following from Bradentown *Evening News*:

GEORGIA SENATE PASSES DRASTIC LIQUOR LAW.

ATLANTA, Nov. 9.—The Georgia State Senate, in session here, passed the Mangham-Ransom bill prohibiting liquor advertisements in any form in Georgia.

The provisions of this bill make it a misdemeanor to offer for sale any newspaper, periodical, or magazine which contains such an advertisement.

Now, then, say what you like about Georgia, but give her credit for the above. What other state dares follow suit?

"BOOZE" ADVERTISEMENTS—ANOTHER GREAT CITY DAILY TURNS THEM DOWN.

The Detroit Journal to eliminate whisky, low theaters, and objectionable copy from its advertising columns.

No whisky advertisement, no objectionable medical advertising, no dubious financial advertisements, no parasitical advertisements, no debasing theater advertisements, no loan-shark advertisements, no unclear or doubtful advertisements of any kind will be accepted by *The Journal*.

To *The Journal's* 500,000 readers, and to its thousands of advertisers, to all the world, we make this bold and resolute announcement.

It has been our advertising policy in the past to refuse everything that seemed positively injurious, vicious, or debasing to the public taste.

The Journal has, after years of militant labor in the interests of a cleaner Detroit, found itself to be the acknowledged leader and exponent and mouthpiece of public decency.

From *The Detroit Journal*, October 28, 1915.

"TWENTY-FIVE TIMES" AS MANY WITH SALOONS OPEN.

Senator Peterson quoted from police records to show the enormous decrease in drunkenness in Moorhead, Minn., after the saloons were closed. For July, August, and September, 1915, there were 88 arrests for this cause as compared with 2165 for the same three months of 1914, or approximately twenty-five times as many arrests for drunkenness with the saloons open.—*Union Signal*.

"GOD'S KINGDOM COMING."

A most excellent and exhaustive article in the *Christian Herald* for Nov. 10, entitled "The Race-wide War on the Liquor Traffic," closes with these words:

"The great world movement against alcohol is helping to answer Christ's prayer: 'Thy kingdom come. Thy will be done on earth as in heaven.'"

Safety First Steel Document Box . . Valuable Paper Wallet

The steel DOCUMENT-BOX has a black ebony finish, is fire-resisting, has a double-hinged cover fitted with spring lock and two keys. It is eleven inches long, five and one quarter inches wide, and two and one half inches deep. As it is meddler-proof and curiosity-proof, it gives one an opportunity of filing away those valuable papers, letters, and keepsakes with which one does not care to have others become familiar.

The PAPER WALLET which fits into the DOCUMENT-BOX is not shown in the illustration. It has a strong, finely grained cover fitted with eight tough manilla-paper envelopes for documents, with printed forms for each and classified as follows: Notes and Mortgages, Last Will and Testament, Contracts, Deeds, Life Insurance Policies, Fire Insurance Policies, Clippings, and Memoranda.

Send us ONE NEW yearly subscription to GLEANINGS and TWO new six months' subscriptions, remitting in payment \$1.50, and we will send as premium without additional cost one of these DOCUMENT BOXES and PAPER WALLET.

OR

Send us ONE NEW yearly subscription to GLEANINGS with remittance of \$1.00 plus postage on the PREMIUM which weighs about two pounds, and we will send you the box and wallet as premium.

Canadian postage 30c a year extra; 15c extra for each six-months' subscription.

NO. 24

EDITORIALS

THE reader will be interested particularly in an article in this issue by B. Keep, about the man who built his fine house from cellar to gable himself with the money he made from his bees.

THE National Beekeepers' Association will hold its next convention in Chicago on Feb. 22, 23, 24. Fuller announcements will be given January 1. Chicago is a convention city, and the attendance at this meeting ought to be a record-breaker. Every one who can should make his plans to go.

MR. FRANCIS JAGER, of the State University of Minnesota, is sending out to the beekeepers and farmers of his state a circular letter on wintering bees. It is short, crisp, and at the same time orthodox in its teachings. It will do a great deal of good to a large class of farmer beekeepers who do not know the fundamental principles of good wintering.

WE take pleasure in referring to our index, which has been prepared with unusual care. The reader, in order to get the most out of his subscription price, should, with the index before him, go over his back numbers for the year, especially during the long winter evenings, as many an article that he was compelled to skip in the rush of the season he can read and digest.

An Alabama Queen-yard

A COCONUT-TREE was the most prominent feature of our December first cover picture. This time it is a long-leaf pine, which shelters a portion of the queen-yard of W. D. Achord, Fitzpatrick, Ala., who writes the article entitled, "Building up a Business in Shipping Bees without Combs," which appears on page 1031 of this issue.

The cover illustration shows a portion of his 400 mating-boxes at the home yard, as they looked the latter part of September.

this year. Mr. Achord's residence stands in the rear of the picture.

Wintering Experiments on a Large Scale

ATTENTION is drawn to an article on wintering, by J. J. Anderson, in this issue. Mr. Anderson is one of the extensive beekeepers of his state—a man of wide experience, and one well qualified to speak on almost any question relating to bee culture. He tried a series of experiments during the winter of 1914 that are interesting and valuable. Instead of trying out all these different ways of packing on a small scale he went at it in a large way, so the results are all the more conclusive.

We called on him last winter, and the photographs will help to show the different methods he used for wintering. The results go to show that the cellar came out a little ahead; and next in order in good wintering was the Holtermann winter case, leaving the other bees, packed in long rows, to come out third and fourth.

Testing out so many colonies with upper entrances we regarded as a bold experiment; and while the result is, perhaps, not surprising, it is worth something to know that practice bears out theory.

Catch the Eye of the Cook

THE editor of *The Mabel Record*, Mabel Minn., has started something. He has begun to publish in his paper recipes from GLEANINGS for October 1, and will continue to print three or four of them in each issue until the close of the year. On January 1, 1916, the woman who reports on the largest number of recipes will be given a gallon of extracted honey.

Recipes of this nature are sure to prove interesting to readers. Here is an idea: Get the editor of your local paper to run a column or so of recipes in the same issue in which your advertisement appears. Live

matter of this kind not advertising any particular honey he ought to be willing to print free of charge, especially if you buy ten or twelve inches of advertising somewhere else in his paper.

The women will find the column irresistible. Your honey advertisement will pull harder than it ever pulled before. The beekeepers who market honey locally can not afford to neglect such opportunities as this.

Olive Oil and Honey as a Tonic

OUR attention has been called to the following clipping from the Home Department of the *National Magazine* for August, last year. This happens to be a preparation that we have tried ourselves, and found pleasing to the taste. What a blessing it would be to humanity in general, and, incidentally, to beekeepers in particular, if all who take olive oil would take it with honey!

OLIVE OIL WITH HONEY.

Olive oil is one of the finest flesh-builders and nerve foods in the world, and I often wonder why parents do not give it to the children more than they do. Combined with honey, which is also valuable as a food and a blood purifier, it makes an ideal tonic, and the oil cannot be distinguished. Try a teaspoonful of each before meals or after, or with the meals; the amount may be increased if desired. In the absence of honey, any sweet fruit juice may be substituted, and makes a much more palatable combination than the acid juices, such as lemon, grape juice, etc., which are usually recommended as a disguise for the oil. Children, especially, prefer something sweet.

A New Bee-book, "Productive Beekeeping," by Frank C. Pellett

SCARCELY had Dr. Phillips' book, "Beekeeping," issued from the press of the Macmillan Co. than the announcement came that there is still another new book just from the press of the J. B. Lippincott Co., Philadelphia, entitled "Productive Beekeeping," by Frank C. Pellett, State Apiarist and Foul-brood Inspector of Iowa. Mr. Pellett is not only a student of apiculture but also of natural-history subjects. The new volume contains 340 pages of original matter and 134 illustrations, mainly half-tone engravings from photographs taken by the author himself.

While we have not been permitted to see the completed volume, the publishers have kindly placed in our hands proofs of the pages up to 298. We have not read all this work page by page, but we have gone over it enough to know that it is safe and orthodox in its teachings. While the author believes that a few minor methods are original with him, the book is not presented

for the purpose of exhibiting original material, but to describe the best methods gleaned from every possible source. In no sense can it be said to be a rehash of material from other works.

The book is well worth the price asked—\$1.50. The same can be had from this office, or we will club it with *GLEANINGS* for \$2.10 postpaid. Canadian postage 30 cents extra, and foreign postage 60 cents extra.

Self-spacing by Hive-rabbets Rather than by Projections on the Frames Themselves

THE article by A. Butsch in this issue shows a method of spacing frames by means of notches in the hive-rabbets. While we don't like to throw cold water on the proposition, the public should know the facts. Our correspondent said he thought of patenting it, but we doubt if he could secure a valid patent in view of the patents that have been granted on the same principle. There are many modifications of it, and the principle has been tried out over and over again, only to be abandoned sooner or later. In our A B C and X Y Z of Bee Culture, under the head of "Frames, self-spacing," will be found a variety of self-spacing rabbets—see page 256 of the last edition.

The objection (and it is a serious one) is that, in moving bees out to outyards, the frames will hop out of their place when colonies are drawn over rough roads. Another serious objection is that the frames cannot be handled in groups of threes and fours like those having spacers on the frames. The very fact that the rabbit scheme of spacing is born again and again, and that it dies almost as soon as it is born, shows that it cannot hold its own with the scheme of having the spacing device on the frame itself.

Our correspondent speaks of the necessity of having a grindstone handy to sharpen the honey-knife when extracting from metal-spaced frames. We have extracted here at Medina a great many tons of honey from metal-spaced frames. We do not sharpen the knife except as it becomes dull after half a day's uncapping. We find no necessity at all for bumping against the metal projections.

A New Edition of "Fifty Years Among the Bees," Again

IN 1885 Dr. C. C. Miller, of Marengo, Ill., got out a modest little volume entitled "A Year among the Bees." This, like the

subsequent editions, was as entrancing as a romance. When the edition was exhausted a larger and more pretentious volume was gotten out by the doctor, entitled "Forty Years among the Bees." This was in 1902. This again was exhausted in 1911, when the first edition of "Fifty Years among the Bees" appeared. This, like the previous volume, contained a good many original photographs and a general revision. Still again another "Fifty Years among the Bees" has come from the GLEANINGS press. "It's a dandy." It still bears the title of half a century, notwithstanding four years more have been added to the time. The last edition was not revised as extensively as the former editions, and this only goes to show how nearly Dr. Miller in the first edition of "Fifty Years" got down to rock bottom. But, nevertheless, here and there occur slight changes. The most important changes relate to his record-breaking honey crop in 1913, to his later experiences in fighting European foul brood, and to minor changes in methods here and there; otherwise the two editions of "Fifty Years" are very much the same.

In all there have been sold of Dr. Miller's books under the various titles, or will have been when the present edition is sold, something like 18,000 copies.

Dr. Miller, notwithstanding he is past 84, when most men would have passed to their reward, is still very much alive and very much of a beekeeper. By Dr. E. F. Phillips he is considered to be the best comb-honey producer in the United States if not in the world. At all events, Dr. Miller's methods have been utilized and copied all over the world. He has originated methods and processes in the matter of swarm control and in the production of comb honey that help make him "the grand old man" that he is in the bee-world today, revered and respected everywhere, not only for his beautiful spirit, but for what he has done.

Just in the matter of comb-honey production alone "Fifty Years among the Bees" is worth many times the price, \$1.00; or clubbed with GLEANINGS for \$1.50. Canadian postage 30 cents extra, and foreign postage 60 cents extra.

A Serious Situation in Florida

OUR readers will remember Wilmon Newell, formerly State Entomologist of Texas, who did such good work in bee-culture investigations and who for years was unremitting in his efforts to secure a foul-brood law in Texas. He finally succeeded,

but failed to get the necessary appropriation to carry it into effect. Later on this was secured; but along about this time the powers that be in Florida began to look for a good man to handle a most alarming situation in their state. To make a long story short, Mr. Newell was called to and accepted the position of Plant Commissioner by the State Plant Board, Gainesville, Florida. The announcement of his acceptance was given in this journal for September 1st, page 696.

In his new position Mr. Newell has not been idle. He and his associates are doing all in their power to avert a situation more serious than foul brood—a situation that has already cost the state of Florida many thousands of dollars; and unless it can get more money to handle the problem it will be the ruination of the citrus groves of the whole state.

It appears that the disease known as the citrus canker was imported a couple of years ago into Florida from Japan. This disease is awfully virulent, makes rapid headway, and has now found its way into seventeen counties. The worst thing about it is that there is no cure except the complete extermination of the orchards, tree, root, and branch, by fire. The sprays that are effective for ordinary diseases are absolutely powerless.

Florida has already appropriated \$125,000, and a like sum has been contributed by the Florida orange and grapefruit growers. The result has been that, so far, every infected tree or orchard has been burned. Mr. Newell and his associates say their funds are running low, and that the disease will break out again, because there are other trees and orchards that are probably diseased, but where the canker has not as yet shown itself. What are now most urgently needed are funds to provide adequate inspection work to catch the disease as soon as it breaks out.

Florida is appealing to the United States, which has already appropriated \$35,000, \$22,000 of which went to Florida, to hold the disease in check; but before the Florida legislature can meet again, there is urgent need that Uncle Sam reach down in his pockets and help not only Florida but other states like Alabama, Mississippi, Louisiana, and Texas, where the disease has already taken a foothold.

Our readers are urged to write to their Senators and Representatives, urging them to support any bill or appropriation that will tend to prevent the utter annihilation of the orange, grapefruit, and lemon business.

Perhaps this proposition may not interest beekeepers; but it should be remembered that beekeeping and citrus-growing go hand in hand. Orange honey is getting to be one of the commercial honeys that is very highly prized. While the amount is not large, it is sufficient to attract the attention of every beekeeper who would protect his industry—especially the industry of his fellow-beekeeper in states where the production of orange honey is possible.

In the mean time we congratulate the people of Florida on having so able a man for Plant Commissioner as Professor Newell. He is by training and general temperament eminently qualified to handle the situation.

The Economy of Honey as a Food

CARBOHYDRATES, usually in the form of sugar or starch, are the elements of food important in furnishing energy. Since honey is richer in carbohydrates than in other food elements, it comes in the class of energy-producing foods. Honey contains very little protein, the muscle-forming element of food, and no fat. The ash and undetermined matter shares in forming bone and aids digestion.

The unit of comparison of foods is the calorie. This is, approximately, the amount of heat which would raise the temperature of 1 lb. of water 4° F. The energy value of honey is about 1485 calories per pound, which means that if *all* the heat potentiality in a pound of honey could be utilized it would raise the temperature of 33 lbs. of water from freezing to the boiling point.

Basing food value upon the amount of energy in calories to be derived from a food, and taking the average prices into consideration, honey is a more economical food than pears, oranges, figs, bananas, strawberries, and grapes, other foods in the same class of energy-producers. Of foods in other classes, honey is more economical as an energy-producer than celery, tomatoes, canned corn, and all the meats, with the possible exception of pork chops. On the other hand, it is less economical than bread, cereals, potatoes, baked beans, sugar, and apple.

These comparisons were made from studies and tables from the U. S. Department of Agriculture and other sources. The diagram below illustrates graphically the constituents of an average jar of honey. The flavor of honey depends largely upon the presence and proportion of the elements bracketed as "undetermined matter."

Iron, lime, sodium, sulphur, magnesia, potassium, manganese, phosphoric acid, pollen grains, albumen, aromatic bodies (terpenes, etc.), higher alcohols (manitol, etc.), and various other bodies of indefinite or unknown character.

Dr. C. C. Miller

STRAY STRAWS

Marengo, Ill.

JOHN L. BYARD uses candy and foundation in mating-boxes, p. 941. Swiss beekeepers use candied honey, without comb or foundation.

THE EUROPEAN war pinches where one would hardly expect it. *The British Bee Journal* has cut down its number of pages because the war has made it impossible to get enough paper!

EARL SEAMANS, I quite agree with you, p. 932, that European foul brood is not such a dreadful calamity, but I don't agree in thinking the queen must in all cases be killed. You caged a queen, gave clean combs, and the disease returned. I've caged a good many queens, gave no clean combs, but left the diseased combs, released the queen in ten days, and in the great majority of cases there was no return of the disease. In a very bad case I would kill the queen; but a good beekeeper should never allow a case to get so bad as to need the queen killed.

R. F. HOLTERMANN, p. 944, you think I never saw a moving-picture show. Oh, yes! I'm fond of a good movie. Then you want to know how many straight lines there are in a circle. I suppose you want me to say an infinite number of infinitely short lines. But I know a better answer than that—there's only one line, "a curved line," as the dictionary has it. And now I'll agree that, when there's danger of a comb breaking out, your way of handling is excellent; but just as soon as possible I'd try to have all combs so that so much ceremony would not be needed.

FRANK L. POLLOCK relates, p. 937, "that almost every bee that took wing loaded from the cappings ejected a fine spray of fluid before reaching the window." That reminds me that when bees are robbing a hive or a super, especially if the entrance be small, all about the entrance is daubed and sticky. May it not be merely the ordinary evacuation? [You will remember we reported how bees taking thin syrup from an outdoor feeder would emit a fine spray on taking wing. We had supposed that this fine spray was nothing but water, and that it was a trick of nature which we have not fathomed, by which bees can, while on the wing, eject a large amount of water either from nectar or from thin syrup. If the bees cast this spray while gathering thick or well-ripened honey immediately on tak-

ing wing, then our fine-spun theory has received a jolt.—ED.]

E. F. ATWATER, you gave me a scare when you came down so savagely on dummies, p. 928; but on reading further I found you objected only to their flimsiness. You're dead right in that. Such flimsy things as I've seen sent out are a disgrace to manufacturers. But aren't you a bit off in thinking that a dummy not over $\frac{3}{8}$ thick must necessarily be flimsy? I had a few an inch thick, but nearly all are 5-16; and after 25 years' use I don't see but they stand the racket just as well as the inch ones, all but the lugs, and I've remedied that by using a tenpenny nail strapped on with a piece of tin. Neither has there been any trouble with comb built at sides. You say the dummy is sooner or later thrown away. Well, I saw at Ernest Pike's eight-frame hives without dummy, and equal space at each side, and I'm not entirely certain it isn't an improvement. The self-spacing feature is *not* destroyed; and if you stop to think a minute you will see that with the usual arrangement we have less space at outsides than in center, and it seems there should be more. No, there's nothing wrong with a dummy $\frac{3}{8}$ or 5-16 if it's made right, and $1\frac{1}{4}$ for ten frames, with no dummy, is an abomination. [We do not agree with your last sentence. We have been using our ten-frame hives $1\frac{1}{4}$ wide, hundreds of them, at our yards—ten frames without dummies. The fact is, the whole bunch of frames should be placed so that there will be an equal space on each side. The two outside combs may be built out a little in the height of the honey-flow, and that is all. As a general thing, a dummy, no matter what its thickness, is harder to get out of a hive with its full complement of frames than any one of the frames. One manufacturer, and possibly more of them, will leave out dummies in their 1916 hives.]

The ordinary Hoffman frame will, by the accumulation of bee-glue and wax, space wider and wider until the extra quarter-inch is practically taken up. When the frames are new the $1\frac{1}{4}$ -inch width is a trifle wide; but as the frames grow older the increased spacing for each frame makes the $1\frac{1}{4}$ about right. After a great deal of travel we are satisfied that the average beekeeper of large experience does not use dummies with a full complement of frames with either an eight or ten frame hive.—ED.]

J. E. Crane

SIFTINGS

Middlebury, Vt.

Bees here in Vermont are in most excellent condition this fall, and the ground is better covered with clover than for many years past; but our next year's crop of honey will depend on the coming months.

Editorial entitled "The Abuse of Bait Sections," page 831, Oct. 15, is timely and to the point. To my sorrow, I have been caught once or twice by using them. Who can tell why it should granulate in such combs sooner than in newly made combs? and why should comb change to a dirty yellow by standing empty for eight or ten months? and why should honey fed back to finish sections be darker than when fed? Who can tell?

In giving his treatment of foul brood, Mr. Greiner tells us, page 751, Sept. 15, how he saved his hives but burned all his frames and combs. It was well to save the hive, but why burn all the combs? Why not make them into wax worth, perhaps, 30 cents a pound, or quite a dollar's worth of wax to the hive, and then burn the slumgum? The heat will kill all germs of foul brood, and you save just so much.

On page 742, Sept. 15, the editor says of fall-united colonies that "for some reason they do not seem able to get together as one working unit like a regular colony," which reminds me of a yard I visited a few weeks ago. I found the colonies nearly gone with foul brood, and advised the owner to break all up. He was anxious to save some bees, and united five into one colony, putting them into a large oblong hive without frames. When I called on him again I found these five small colonies had clustered in the top of his hive as three distinct colonies—three of them going together at one end and the other two occupying each of the two opposite corners, and each of the three building separate sets of combs.

That article by Allen Latham, beginning on page 887, Nov. 1, is to my mind one of the best, if not the best, in this number of GLEANINGS. Mr. Latham is a typical Yankee, and never does things because some one else does, but does his own thinking, and takes the path that is most likely to accomplish his ends without regard to what others think, or the difficulties in the way.

That the rules he lays down will work where there is a good flow of honey I have not the slightest doubt, for I have produced tons of non-separator section honey myself. But I wanted to call attention to the fact that the rules he lays down are of as great value in the production of honey with separators as without them.

It does one's soul good these frosty mornings to look at those photographs of flowers by J. M. Buchanan, of Franklin, Tenn., on pages 842, 843, Oct. 15. I notice, however, one is not named correctly. It is a boneset, sure, but not *Eupatorium perfoliatum*. There are sixteen species of the boneset family. Mr. Buchanan says the species his illustration represents grows on high lands, and furnishes a good crop of surplus honey of fair quality, light amber in color, while *E. perfoliatum* grows on low lands or in swamps, and the honey, while a light amber in color is quite bitter. Gray says of it that the "leaves are lanceolate, united at the base around the stem;" i. e., they are without any petiole or leaf-stalk, and the stem perforates the leaves; hence the name, "perfoliatum." It is generally known here in the East as thoroughwort.

How beautiful are the lines of Grace Allen on page 881, Nov. 1, "The Lament of the Drones"! How often has a feeling of sorrow and sadness come over us as we have seen the drones driven from the hive to die of cold and hunger! And the workers, too—how brief is their life—not much if any longer than that of the drones, except those which come on to the stage in late summer or early autumn! They may live through the winter only to perish in the spring. But such is life on this earth. The flowers bloom and quickly wither. The leaves that have clothed the earth with beauty through the summer at the approach of autumn drop to earth and turn to dust. And man, even, opens his eyes upon a world of life and light and beauty, and in a few brief years closes them in darkness. What does it all mean? Surely life is the great unsolved problem, until our hearts are touched by the Spirit of the Most High, and we look up and recognize our kinship with the infinite, and hear the words of the Master, "Because I live ye shall live also." Isn't it just grand to think we may live on through the ages while material things perish?

BEEKEEPING IN CALIFORNIA

P. C. Chadwick, Redlands, Cal.

There was an annual meeting of the California State Beekeepers' Association held in San Francisco in August, at which the election of officers was reported. Now comes the announcement that the State

Association meeting will be held in Los Angeles in December. I am wondering how many annual meetings can be held within one year. I had been led to believe one annual meeting was all that was possible within a year, but it seems that I have been mistaken.

There is a certain difference in colonies of bees that is so striking that sometimes it seems the apiarist must get acquainted with each colony. We come to a colony that seems to have time only to rear brood; another is in quest of honey, and the bees are doing their best to store quantities of it, jamming it into the brood-nest to the detriment of the future strength of the colony; another may be strong on pollen-gathering. To manipulate and regulate the course of the individual colonies is the task of the apiarist, and one that will often pay big returns.

It was my great pleasure recently to visit one of the districts of the state where the eucalyptus yields sufficient to give a surplus. My bees are lying dormant or practically so, with very little if anything yielding them a load of pollen or a stray load of nectar, back in the foothill region. But in this land of much eucalyptus I was surprised as well as pleased to see them line out for the blooming eucalyptus. The flight roar was well defined and heavy; the unmistakable weary-winged fall upon the alighting-boards told of nectar in goodly quantities. The inner life of the hive was all excitement with the queens busy, and all of the hive force diligently bending to their task. This flow will last several weeks yet, perhaps until the middle of January, by which time an abundance of bees will fill the hives. Those of us who are depending on wild flora are wondering if we shall get sufficient rain to save our fast-drying crops of filaree that we may have an early source from which to stimulate our colonies.

The much-talked-of "new bee disease" seems to have found its way into the land of sunshine as well as the upper coast re-

gion, where they have eleven months of wet weather and August. So far as I know, the only place it has appeared here is in the vicinity of Fullerton, Orange County. All I learned of it there was from Mr. J. E. Pleasants, inspector of that county. Mr. Pleasants said there was a small district where several apiaries had been and were still badly affected by a disease which he remarked was much the same as described in the October issues of GLEANINGS. There are some queer citations in connection with its appearance. If I am correct, Mr. Pleasants said the disease first made its appearance in the apiary of Mr. Green, recently of New York, who purchased the George Emerson bees.

Mr. Pleasants also told of visiting the apiary of Mr. Seligman last spring, finding them in perfect condition, strong and busy. Within six weeks of that time he was called back to examine them again, Mr. Seligman having reported them dying. Mr. Pleasants went at once, fearing black brood. When he arrived he found the bees crawling out of the hives by the thousands, some hives having dead bees an inch deep in front of them, and the hive force badly depleted. The brood was dying, apparently in all stages. I asked many questions, but Mr. Pleasants seemed to think the disease was distinguishable from paralysis. In many respects he said it resembled that disease, but he had never seen paralysis act just as this disease did.

From the description given in GLEANINGS of its disappearance with good weather it seems at variance with the conditions here. The disease has been persistent during the entire summer in some apiaries, and surely a climate with open sunshine and no rain would oblivate it if that alone were a cure. Three miles from the apiary of Mr. Green, which had the disease so badly, he has another apiary, but over a range of hills. Of the many queens introduced in an effort to eradicate the disease, a part of each shipment was introduced in the apiary last mentioned. It remained in perfect health and fine condition, while the other continued to dwindle away. I should like very much to visit this apiary for my own observation, though I do not claim to be an expert on disease. Mr. Pleasants' opinion should carry considerable weight, as he has been a beekeeper for more than forty years, and inspector of Orange County for a number of years.

BEEKEEPING IN THE SOUTHWEST

Louis H. Scholl, New Braunfels, Texas.

BULK COMB FOR THE NORTH.

Why cannot bulk comb honey be profitably produced and successfully marketed in the North when we are packing and shipping it out every month in the year, including the coldest winter months?

I can see no reason why beekeepers of the North cannot make it profitable business to produce this kind of honey for the market, during the summer months, at least. Granulation, which is the chief argument advanced against bulk comb honey for northern latitudes, would not play any part at that time. We are successfully marketing this product during the entire winter, by packing it as we get orders for it, reliquefying granulated extracted honey and putting it over the packed comb honey warm. It reaches the market in excellent condition, and is sold and consumed before it has time to granulate again.

BULK COMB HONEY AND BETTER PRICES.

With the proper distribution of our honey crops there would be a greater demand for honey and at better prices. This is one great obstacle confronting not only the beekeepers but producers of all kinds. Only the exceptionally well-organized producers are marketing their product with any marked success. Attempt after attempt has been made to organize the beekeepers, although but little has been accomplished in this direction. Consequently the individual has to look out for himself and work up schemes of various kinds to enable him to get his product on to the market. Along with these schemes the production of bulk comb honey for at least the home market and territory near by will work for excellent results. There is not a neighborhood that does not demand some honey; and advice has been all along the line to look after the home market first of all, and then, and not until then, ship to other places. Comb honey is always in demand if it can be obtained at a reasonable price. Section comb honey is necessarily expensive for the masses. But bulk comb honey can be produced so much more cheaply and easily that the price for it is within easy reach of the majority; and as a result a great quantity of the honey from the beekeepers' apiaries would find its way into the home market and prevent glutted conditions in the general market.

BULK COMB, PREPARING FOR ITS PRODUCTION.

This is the time to begin preparations for

next season, and first for consideration comes the necessary amount of supplies that will be needed. Supers nearly always come in for their part in our "preparedness" program. In this connection I should like to emphasize again the matter of preparing for the production of bulk comb honey on at least a small scale during the coming season. I suggest this, not because I am "daffy" on the subject of bulk comb honey, but because I honestly believe that its wider production will result in great benefits to the beekeeping industry, and the beekeepers reap better rewards for their efforts.

In making these preparations you may want to supply yourself with some supers like those we use with shallow frames. The number of requests for information on this subject alone during the past two years has been amazing, and comes from all parts of the globe. More questions are asked about the style of frame best adapted for this purpose; and since we have had over fifteen years' experience with the production of bulk comb honey in all its phases, and with many different kinds of hives and other paraphernalia, we do not hesitate with our recommendations.

On page 1034 is a picture of one of our warehouses in which a dozen of us are shown nailing up a carload of three thousand supers and 30,000 shallow frames for our own apiaries. These are the regular deep shallow extracting-supers, 5¾ inches deep, and holding ten shallow frames 5½ inches deep, making a standard-sized super for the regular ten-frame equipment. Especial attention is called to the fact that the top-bars of all of our shallow frames are only ⅞ inch wide and ½ inch thick. This is a big improvement over the wider and thinner top-bars usually put out by the factories. The improved frames have greater strength, and allow more open space between the frames and from super to super, giving freer communication throughout the hive that is of inestimable value in increased production of honey. The top-bars are not grooved either—the thin-super foundation in full sheets being put in with melted beeswax. The groove is absolutely unnecessary, weakens the top-bar, causes delay by necessitating the tedious insertion of the foundation into it if the frame is grooved, and, after being once filled with wax, it cannot be used again after the honey is cut from the frame, anyway.

CONVERSATIONS WITH DOOLITTLE

At Borodino, New York.

CELLAR WINTERING FOR BEES.

"I understand you have been successful in wintering bees in the cellar. Last winter I was not successful in outdoor wintering. Bees died on the bottom-board during February and March, and dwindled badly in April and May. I wish to try cellar wintering. Is there danger of keeping the cellar too warm?"

With good pure air, 60 to 65 degrees of heat might be borne for a few days; but should that be kept up for four or five weeks it would doubtless start the bees to breeding, which would be very undesirable, especially during the first half of the winter. Then such a high temperature would be liable to cause a loss of bees from their leaving their hives and flying toward the light, if there was any crevice through which the light could penetrate; and if the cellar was totally dark, those that left the hive will be lost on the cellar bottom. We have been told that the bees that leave the hive would probably die of old age under any circumstances, and that their loss on the cellar bottom is better than to have them die in the hive. This may be quite largely true when the temperature of the cellar is kept below the point at which bees are accustomed to seek the open air; but when that point is exceeded, my experience has been that they begin to seek the open air; and the longer their confinement at a high temperature, the greater is that inclination till a loss comes about which is detrimental to very many of the colonies.

I am satisfied that fifty degrees is too high a temperature for successful wintering. Cellars differ; but the right temperature, as determined by the quietness of the bees, will generally be found to be between 42 and 47 degrees. Much also depends on the strength of the colonies. Weak colonies will bear a much higher temperature than the strong ones; but with all weak colonies it will be harder to get and keep the higher temperature without artificial heat.

"My cellar is 20 by 30 feet and 8 feet deep, and I wish to put 60 colonies in it."

With a cellar of that size and the number of colonies mentioned I should judge that the bees would winter all right without any special attention to ventilation. From past experience I should expect that your trouble, if any, would come through the matter of temperature rather than ventilation. The normal winter temperature of most cellars

is generally too low for the successful wintering of bees. If the cellar mentioned is an average one the successful wintering of so small a number as 60 colonies in it may require strict attention. The reason of this is that 60 colonies, without aid, would hardly keep the room warm enough.

If the temperature of the cellar goes no lower than 37 degrees in the severest weather when it contained no bees, it probably would be all right for 60 colonies; but should it go to 28 or 30, then more bees or some other way of raising the temperature would be required to make successful wintering certain. It is well to remember that a cellar which is warm in very severe weather will be cool in warm weather; and a cellar that is too cold in severe weather is apt to become too warm in a mild or warm spell in winter; and with such a cellar one is almost at a loss to know just what to do at one extreme or the other.

"How about getting the bees in the cellar? Is it necessary to use smoke?"

I never use smoke when setting bees in the cellar; and if care is used, no smoke is necessary. Be careful about unduly disturbing them. Put them in at a time when they are not easily stirred. If through any mishap a colony is likely to be thoroughly aroused, they can be kept in the hive by using a cloth of sufficient size to cover the entrance fully. Make the cloth pretty wet, and put it up snug against the entrance so as to exclude all light. However, this wet cloth must be removed as soon as the bees are in the cellar, otherwise a scramble to get out may result in the loss of the colony through overheating and lack of air. Take the bees in on a dark day if possible, when there is little wind, with the temperature between 35 and 45 degrees.

Prying hives up in freezing weather will unduly disturb any colony. See to it beforehand that there be no undue noise, cracking, or jarring, when they come to be taken in; then when the time comes to take them in, pick each hive up firmly but gently, carrying it to its winter restingplace, setting it in place as gently as it was taken from its stand. Two men with a rope of suitable length can carry bees in, so that they will hardly know that they have been moved. And one man with a spring wheelbarrow can do nearly or quite as well by using a heavy blanket or quilt folded so there will be several thicknesses between the hive and the wheelbarrow.

GENERAL CORRESPONDENCE

SOME INTERESTING WINTERING EXPERIMENTS BY AN EXTENSIVE BEEKEEPER IN IDAHO

A Comparison of Four Different Methods

BY JOSEPH J. ANDERSON

In the North the wintering problem will always be a regular part of the beekeeper's work if success is to attend his efforts, just as the wintering of sheep or cattle presents its peculiar problems and brings its exacting labor to the shepherd or cattle-breeder. There is this material difference, however.

When our bees are put away for winter the work is over—no wading through the snow nor exposure to the cold blustering storms, carrying grain or forage or providing them with water.

Not enough attention is paid, at least by the beekeepers of this Rocky Mountain section, to this important problem, although its significance is coming to be recognized more and more. With young and vigorous queens, a hive full of young bees, and ample stores, the battle is half won.

With a view to determining the best method, if such there be, of winter protection, I tried last winter four different methods. At my home yard I put into my cellar, a log structure set into the edge of a hill, and facing the north, 158 colonies. See Fig. 1. These, on account of the mild weather and the difficulty of keeping down the temperature in the repository, I was compelled to take out March 17. It was too early, but the insistent restlessness of the bees compelled it.

Half of these were tiered with bottoms removed, the covers left on. They were set about four inches apart. The lower tier was set on two poles, and the upper tiers,

with the middle of the hive over the four-inch space between the two hives below it, break-joint fashion. The other half I tiered up close together with covers removed and burlap over the frames.

The unrest of the latter colonies as compared with those that had the bottoms re-

moved was very marked—so much so that I found it necessary to remove the bottom-boards from some twenty or more of them and tier as the others, when the bees at once became quiet. Hereafter in my cellaring, all bottom-boards shall be removed.

When these bees were taken out of the cellar, March 10, only four colonies were dead, of which two I knew to be queenless when put in. By May 6, however, 13 more had succumbed, making a total loss of 17, about 10.8 per cent, if the queenless ones be counted. The general condition of these bees as regards strength and vitality was first-class.

At my north yard,

the principal out-yard, 333 colonies were packed as follows. See Figs. 2, 3, 4, 5, and 6.

Eighty-seven were "heeled in," or banked up as shown in Fig. 6. I first prepared 87 bee-escape boards by sawing out a 1½-inch piece from the rim near one corner, and tacking a thin strip underneath to prevent breaking. This made the entrance at the top, for the bottom was closed by dirt. Then these 87 colonies were set in a row facing the south, and as near together as possible. Next an escape-board, with escapes removed, was placed over each hive,

Christmas Fancies

BY GRACE ALLEN

Bees of mine, no longer humming,
Christmas Day is coming, coming,
With its thoughts forever bringing
Dreams of far away,
Of that dim and distant morn
When sweet Mary's Babe was born.
How the bells go ringing, ringing,
Christmas Day!

As he grew a little lad,
Were the bees, I wonder, glad
In sweet Mary's flowers to meet
When day began?
Then from vineyards warm and sunny
Did they garner choicest honey,
Rich and rare and heavenly sweet,
For Mary's son?

May be sometimes in the grass
He would smile to hear them pass,
Buzzing so through all their jolly,
Genial lives!
For these fancies, vague and fleeting,
Bees of mine, I give you greeting,
And I lay a sprig of holly
On your hives.

with the opening in the rim down and to the front of the hive. Then a super with a cloth tacked on the bottom, and filled with packing, was placed over the escape-board, and over all the hive-cover. Then a little straw was placed in front of the hives to keep the dirt out of the entrances and the hives banked up all around with dirt, the only opening being the small notch sawn in the rim of the escape-board at the top. When taken out of packing, April 25, five colonies were dead. May 6 a second inspection showed twenty-four dead, or $27\frac{1}{2}$ per cent loss. Five were very weak.

Sixty colonies were packed in quadruple winter cases as described by Mr. Holtermann, packed with planer shavings and sawdust. See Fig. 2, right foreground.

These wintered well, and on April 25 only one was dead, and this I put in queenless as a test; but on May 6 I found a total of 11 dead, or 18 per cent; very weak, two. In general these colonies seemed to be stronger than the rest in this yard.

One hundred and eighty-six colonies were placed in double rows, back to back, facing east and west. See Figs. 3 and 4. The hives were about four inches apart in the row, and the rows about the same distance apart. I next packed fine chaffy straw between the hives, and covered all over with about two feet of straw stacked so as to shed the rain. Hive-covers were left on.

Of this lot six colonies were dead when unpacked on May 6. At the second inspection I found 31 more, or a total of 37 dead, or 20 per cent. Eight were very weak.

When the bees at this yard were un-

FIG. 1.—Anderson's home beehive-cellar, looking in the doorway.

packed, only 12 colonies were dead. A spell of beautiful warm weather made me think the proper time had come; but cold stormy weather set in, and on May 6 a total of 72 dead colonies was found, and 15 very weak.

It will be seen that at the time of unpacking my losses were practically nothing; but ten days' stormy weather produced considerable havoc. The cellared bees wintered best of all; next, the bees in the quadruple winter cases; then those packed in straw, with those heeled in bringing up the rear, showing $27\frac{1}{2}$ of loss in the spring storm.

In my field notes I find the following under date of May 6, 1915: "I shall not practice heeling in (banking up with dirt) any more; loss too heavy; bottoms wet and soggy; combs more or less moldy."

"The bunch of bees bought of — last year were very strong; only 2 gone out of 53, and one of these was queenless. I recall now that on account of being very busy I did not get these bees until late, to take them out of packing May 14.

FIG. 2.—Anderson's north yard, showing bees packed for winter.

FIG. 3.—J. J. Anderson's straw-covered rows of hives.

I cannot account for the secret of this splendid wintering unless it was staying in packing until so late."

These were packed in straw, as outlined above. Hereafter a few fine days shall not inveigle me into unpacking. I shall be in no hurry.

Next spring I shall again furnish your readers with the results of my experience during the coming winter.

On January last, on his western trip I was delighted with a visit from our friend Ernest. He took a number of views

illustrating the methods I was trying. The cellar wintering he pronounced perfect.

Salem, Idaho.

[As Mr. Anderson states, we called on him during the month of January, and had the privilege of seeing not only bees in the cellar, but those at the outyards packed according to the methods above described. The bees in the cellar at the time of our visit seemed to be in remarkably nice condition (see Fig. 1). At that time we took the picture looking into

FIG. 4.—The windbreak on the south along the irrigation ditch.

the doorway. There was nothing to indicate that the bees in hives with bottoms were not doing as well as those with the bottoms removed. We explained to Mr. Anderson that there were two schools—the one advocating leaving the bottoms off and the other leaving them on, and that we should be interested in knowing which lot of bees in the whole number came out better. He tells us that those without bottoms were much quieter. The cellar was comparatively small for the number of bees in it, and we are not surprised that the bottomless hives showed up better in the spring. But where the cellar is relatively larger, it has been our experience and observation that the colonies with bottoms come out in better condition. We had an experience one winter in one of our cellars where the colonies with bottoms on were the only ones that wintered well, while those without bottoms showed a heavy loss of bees, many colonies dying outright before they were taken out of the cellar. It follows, therefore, that the question of whether bottoms shall or shall not be used on hives depends on the size of the cellar, the temperature, and the number of colonies wintered. We should say that, with a cellar 10 x 15, and 8 feet high, the bottoms had better be left off if as many as 100 colonies are put in. With half that number we would leave the bottoms on.

On arriving at the north yard with Mr. Anderson we were very much interested in the different methods of packing. These experiments on so large a scale would be invaluable as the sequel has proved. We expressed to him the opinion that those in big quadruple cases of the Holtermann type would fare the best, and they did. When

FIG. 5.—Mr. Anderson himself and some of his colonies packed in Holtermann winter cases.

we came to look at the colonies that were heeled in, with upper entrances through the edge of the escape-board at the top, we were surprised and interested (see Fig. 6). We expressed a fear that the hot air at the top of the cluster would escape too easily through the top entrance, for it should be understood that the lower part of the hive up about two-thirds of the way was heeled in with dirt and packing. This, of course, closed the regular lower entrances. The fact that there was a heavy loss in this group was not surprising. Still, the loss was not nearly as large as we thought it would be; for it seems to be a fundamental principle that hive entrances for colonies in winter quarters should be at the bottom, primarily to hold the warmer stratum of air that naturally rises to the top, and is confined because it cannot escape.

The group of hives that were placed in long rows back to back we thought ought to winter nearly as well as those in Holtermann cases. See Figs. 3 and 4. There is one objection to this plan, and that is, bees in long rows are inclined to drift. When the weather is such that they can fly, and

FIG. 6.—The hives that were heeled in with dirt; entrances at top.

FIG. 7.—Anderson's wax-rendering boiler, and the frames that had been put through the boiler to free them of foul-broody combs.

when bees will come out by the thousands those entrances where there is the greatest commotion will draw from the other entrances that make no demonstration. This has been the experience of many beekeepers.

We took a number of photographs as shown from 1 to 7. Fig. 1 shows a view looking into the doorway at the home cellar; but only the hives, of course, in the foreground can be seen.

Fig. 2 shows colonies in the middle background packed in the Holtermann winter cases.

Fig. 3 shows those colonies that were packed in long rows back to back and close together, covered with loose straw and brush over all to hold the straw down. Mr. J. J. Anderson is seen in the foreground.

Fig. 4 shows a more distant view of the hives packed in long rows with the honey-house and the windbreak of trees on the south along the irrigating-ditch in the foreground.

In Fig. 5 Mr. Anderson is again seen sitting on one of the winter cases.

In Fig. 6 we have the group of hives that were heeled in at the bottom with upper entrances. It will be remembered that this group showed up the poorest of any.

In Fig. 7 we have an exhibit that perhaps

no one of our subscribers desires to have. The pile of brood-frames in the right background originally contained combs taken from diseased colonies. The structure in the foreground contains a large flat boiler heated by an arch from beneath. The smokestack in the rear furnishes the necessary draft. The little boy in the foreground is one of Mr. Anderson's children.

Mr. Anderson made no concealment of the fact that he had had American foul brood; but the pile of frames showed that he must have had a "big dose" of it, and, what is more, that he had gone at it heroically to clean it up. He believed he had done a clean job.

This large boiler was used for melting the combs; and when the combs were free the frames were thrown on this pile after being immersed in hot water. With all the honey and wax removed, there would be practically no danger of further infection. Many of the frames were damaged, others were odds and ends, and he was not sure whether it would pay him to use them again or not. He was inclined to think he would not take the chance. While they were harmless in the pile, there might be danger if new combs were built into them again.

The winter weather in Idaho seems to be like that of Ohio—climate drier.—Ep.]

My home aping depends on the flora of the marshes for supplies. We have several hundred acres in this locality, which in favorable years yield a heavy flow. In 1913 my crop was 382 lbs. per colony, nearly all from the buff margined — WILLIAM WESTON, Eslington, Pa.

HOME-MADE VS. FACTORY-MADE HIVES

BY LEWIS L. WINSHIP

The question of home-made vs. factory-made hives has been discussed pro and con until it would seem highly improbable that more remains to be said. Such does not seem to be the case; and the more said, the more remains to be said. In years to come, there is some chance that this question will be settled once and for all.

To my way of thinking it might as well have been settled years ago. There is only one conclusion to which a fair-minded thinker can come; and that thinker, when he comes to a conclusion, will want factory-made hives. The average home-made hives are fit for nothing so much as kindling-wood. For this they are excellent, as the coating of propolis on them saves kerosene. If you happen to be a representative of that class of noble, and high-minded men, viz., bee inspectors, I know you will quite agree with me.

I am speaking on good authority, as last spring I took three hives (if you can call them by that name) of bees on shares. I was to have all the increase and half of all the marketable honey secured. The man from whom they were taken was a nursery-stock agent; and so, when the busy season for the bees was on, he was also busy with his nursery stock. He spent his time in the winter making new hives and, when prosperous, had many colonies of bees. But as time passed his bees dwindled down to the three colonies as bees will whose owners make their own hives. Now, do not think that I mean no beekeeper can make hives as good as the factory-made article, because some few of them can; but (and here is the "rub") they usually try to economize in every possible way; and the hive when finished usually looks like the one in the illustration.

Beekeepers seldom try to make frames, as they know that the factory-made article is far superior to their best efforts. But this man was one of a reckless few. He may have thought he could do it, but he could not make me agree with him. Every one is prone to believe that he can do any thing better than the other fellow; but it is rare that the other fellow agrees with him. The probable reason for the delusion was that he never opened a hive, and so could not see why his frames were not as good as those factory-made. Why, this man was even feeding his bees dry sugar in a little saucer above the frames in April, and wondering where the honey was coming from, as they were not using any of the sugar.

He did not stop to think that there were blossoms all over God's green earth, all of which were abundantly yielding nectar.

Starting with the cover I shall describe one of his hives similar to the one in the photograph. You can see that the structure is made of a drygoods-box, and that one corner of the cover is at least three inches lower than any of the others. When the sun shines very bright and hot, the cover serves to some extent as a shade-board; but, oh my! when the first rainstorm struck it I came near taking it into the house for a sieve. The water poured in torrents between the combs, and the poor little bees were washed out the entrance. The first thing I did after the shower was to put tin over all three of the covers and paint them two coats, to prevent a similar disaster.

The hive was made from a drygoods-box.

The super was one of the greatest pieces of ingenious mechanism I have ever had the sorrow to look upon. A Philadelphia lawyer could not place empty sections in it. I did not attempt such a hazardous job, but set a factory-made super in its place. Even if a lawyer could have put sections into it, a preacher would most certainly have discharged a volley of oaths if he had had to remove the sections when they were full of honey.

The brood-chamber, if it may be given that name, was more a nursery for worthless drones; and if the hive were mine it would certainly have been used for kindling-wood, and the bees transferred into an up-to-date factory-made hive. The frames were

all built one way of the hive; but through his trying to economize on foundation the combs were built this way and that, making it practically impossible to remove one frame without removing them all. The lumber probably cost as much as would a whole new factory-made hive. As you will notice in the illustration, the maker strived to have his hives easy to handle by grooving out blocks and nailing them to the body.

It must have taken him at least a day to make a hive. Valuing his time at even two dollars a day, which is a very conservative estimate, and figuring the cost of the lumber at par, you can very easily see that it would have paid him well to purchase his hives from some reliable manufacturer. I have not mentioned the gratification one feels on opening a factory-made hive and seeing how every part fits. After using them side by side for two years, one appreciates the factory-made hive more and more.

You beekeepers all know that it is not so much the amount of brood-comb in a hive that counts, but the amount of worker comb. To get all or nearly all worker comb in a hive you must use full sheets of foundation or else get your bees to working on

starters at just the right time of year. Few beekeepers know just when this time is, and therefore it behooves us to use full sheets of foundation and not risk getting a lot of useless drone comb in our hives.

To all beekeepers who will persist in making their own hives, let me say, buy your frames and use full sheets of foundation. With lumber as high as it is now, it hardly pays a would-be carpenter to experiment with it. The hive shown, with the exception of the cover, is better than the usual run of home-made hives, and you must be quite a carpenter to make one as good. I would as soon get a full-blooded horse or cow and put it in a shack, every crack of which you could throw a cat through, as to put bees into ninety per cent of the home-made hives.

When purchasing your hives be sure to get those having a metal roof—that is, if you live in a climate as severe as that of western New York. If I have not persuaded you to purchase factory-made hives instead of making your own, a glance at the photograph will at once cause you to make up your mind.

Springville, N. Y.

A COTSWOLD VILLAGE; GLIMPING OLD-TIME BEEKEEPING IN RURAL ENGLAND

BY A. H. BOWEN

There is nothing more soothing than the languid content that broods over an old-fashioned garden plot in a Cotswold village, with its careless order and unsystematic arrangement. It is all the more beautiful because everything is allowed to flourish in

its own sweet way, and the colors blend one with another in perfect harmony. It is here, too, that the old straw skep abounds, and where bee lore and quaint customs survive among the simple village folk.

As September wanes, the bee-master pre-

A corner of a typical Cotswold skep apiary. Three stocks gave eleven swarms, "casts and lobs," and made the owner justly proud of his extensive apiary.

Straw hackles keep the hives cool in summer and warm in winter.

pares to gather from his unpaid laborers the result of their summer's toil among the blossoms. The annual honey harvest is a welcome and looked-for pleasure to all who keep bees in the old-time way, and the skep supplies yearly a quantity of delicious honey that is carefully kept for use in the long winter months. The time was when this yearly looting of the little brown workmen was a much more serious matter than now.

Before the sugar-cane was domesticated from the wild weed, and the various other sources of sugar had been utilized it was upon the village skeppist that the community relied for its sweet. It is pleasant to visit a Cotswold bee-garden at this time of the year.

Nestling in a quiet corner overhung with lilac bushes could be seen an irregular row of a dozen hives, each on a stool of its own, with a covering or thatch of straw hackle, clipped away at the entrance, and surmounted by an iron hoop to keep it rigidly in place. If in a talkative mood the owner

might be induced to explain which lots were the prime or first swarms that "ring out" for a week in a mass from the entrance, and finally swarmed on a hot sabbath morning; or of the nimble "cuts" that came out and returned several times before they allowed themselves to be captured and placed on a stool to commence for themselves "the daily round and common task" of collecting honey.

A cottage off the village street. It has been inhabited by its present owner and father before him for nearly 75 years. The rental of this, a productive garden, pig-styes, and potato-shed, is three pounds a year (\$14.55), an amount the owner considers very dear.

A progressive Cotswold garden apiary. Notice that the owner has launched out into a few modern hives, homemade but serviceable, from which good returns of honey are obtained.

And so the months of summer would go by until, with the arrival of September, the bee-master would prepare to gather "the fruits in their season." In the crimson gloaming of late evening might be seen a dusky figure moving among the hives. It is the beeman "hefting" his skeps, and marking those which shall be "taken up," and these, too, that must remain to provide swarms next season. Next he digs a shallow pit near by; then a piece of brown paper thickly plastered with brimstone is let in the left of a small stick stuck at the bottom of the hole, and lighted, and as the

the sulphurous flame burns brightly the heaviest hives are lifted over and earth thrown against their sides to keep in the fumes. A sudden fearsome buzzing arises from the skep; but it is gradually hushed to a deathlike stillness as the deadly sulphur smoke does its work of destruction.

Then the honey is set a-dripping over a pan in the cool larder, where the wasps cannot infest. When all runs out the crushed honeycombs are washed to make a cask of methheglin

and then rendered down into wax. Taking-time reduces the hives to half the summer number, and each lot would be carefully plastered to its stool with mortar as a winter precaution against mice that might creep in when the bees were dormant.

Whether the bees are suffocated or got from their hives by the more humane practice of driving, it matters not to the villager who leaves the whys and wherefores to wiser heads than his own, knowing only sufficient to make the humble skep a source of income.

Cheltenham, England.

J. Y. DETWILER

BY E. R. ROOT

Down in Florida, at New Smyrna, is a man named J. Y. Detwiler—the only J. Y. Detwiler in the world, for the simple reason that there could not be another. He is one of the most unique characters that one ever meets. As he says of himself, he is an "everlasting talker;" but his talk is not idle nor without pith, point, and ready wit. It is as good as a circus to hear him talk as he draws on his wonderful fund of information.

A beekeeper? Yes, for many years away back in Toledo, where he formerly lived. An orange-grower? Yes, he knows all about the business. A landowner and real-estate agent? He knows every angle of that line, and can talk interestingly to you about good and poor lands in Florida for hours

at a time. Fish and game? Yes, he knows about all the animals that walk, creep, or swim in that south land. He is, or was at the time of my visit there, two or three years ago, the game and fish commissioner of Florida. That he would make a good commissioner—one who would enforce the law to the very letter—can be plainly seen in that strong face and the tightly drawn lips that seem to bespeak "You obey the law or take the consequences."

Mr. Detwiler is so well known that an artist or sculptor, seeing that face, said, "Oh! here I have a model;" and he set to work to reproduce the original in clay. We secured a photograph, and the picture before you shows the only J. Y. Detwiler who ever lived or ever will live—the loquacious

irrepressible Detwiler. A photograph of the living subject could not be more accurate than this model in clay, for it shows the man at a single glance as he is.

I made Mr. Detwiler's acquaintance in Toledo some years ago when Dr. A. B. Mason was alive. The two were fast friends. One day at a bee convention Mr. Detwiler came in with a very crooked stick and said he wanted to present it as a souvenir to the venerable Dr. Mason, the presiding officer. He could "talk by the yard," but he could not make a "presentation speech." Then he asked Mr. Emerson E. Hasty "to do the job"—the same Hasty who delighted our readers some twenty and more years ago by his bright and breezy articles. Mr. Hasty jumped to his feet; and as he did so he said, "Do you want me to make a speech right on the spot?"

"Right on the spot," responded Mr. Detwiler.

As the former looked at the latter, and saw his rough exterior, he cast his eyes on the cane with all its knots and curves and crooks; and as he looked at the venerable president with a beaming smile, Mr. Hasty's face suddenly lighted up.

"Sir," said he, "I see in this cane some knots, some twists, and some curves; and I see in it strength and character. It has had some rough experiences. It is like the man who gave it, and it is like the man who receives it. Both are men whom I delight to honor. I thank you." Then he took his seat.

Some twenty years after this event, and when I had forgotten all about our old

Clay portrait bust of J. Y. Detwiler, of Florida.

friend Detwiler, I ran across him at New Smyrna, Fla. I say "ran across" him. He had written that he hoped I would call and see him. That he entertained me by his continuous flow of words goes without saying.

A HOUSE BUILT BY THE BEEKEEPER, AND PAID FOR BY THE BEES

BY B. KEEP

Accounts of successful beekeeping as a livelihood are interesting and encouraging as showing the spirit of hopefulness and persistence which animates the real beekeeper. The real, simon-pure beekeeper should be classed with the natural-born inventor who always sees success ahead, and is sustained by hope and faith in his efforts until success rewards his labors.

It is not often that the liking for honey induces one to take up beekeeping; but Robert B. Spicer, of Wharton, N. J., confesses that his love of honey made a beekeeper of him—not at the first with any thought of making it his lifework; that came as a natural sequence.

Mr. Spicer grew up in the country where there are more boulders than tillable soil—

in fact, in the iron-mining section of New Jersey, and soon found more profit in cultivating bees than stony hillsides. He has been at it now more than twenty years.

He has had his "ups and downs" too, having been entirely cleaned out by foul brood about ten years ago; but through that experience most valuable knowledge was gained by which he has since been able to keep his bees free of diseases to the present time. He was able to save most of his equipment, and has hive bodies still in use which were disinfected with a blow torch at that time—the disinfection being evidently entirely effective.

Mr. Spicer has been engaged during the last six years in raising queens, and is about the only beekeeper of this state large-

Spicer built it himself, cellar to gable, and—

ly in the business. This specialization is also the result of circumstances. At first he raised queens for his own use only; but, having a small surplus, he placed a two-line advertisement, which soon brought a demand which required so much of his time that he finally turned his attention to queen-raising exclusively.

Well, not "exclusively," for he took time to get married, and then began to build a

more dearly than if it had been "showered" upon them.

In July last year the New Jersey State Beekeepers' Association held its summer meeting at Mr. Spicer's yard, to which about eighty people found the way, although it is two miles from the trolley up among the hills. They enjoyed a practical day with Mr. Spicer among the bees, not forgetting the generous hospitality.

the bees paid for it.

home. That's a genuine fact for he personally built it, from digging the cellar, mixing and laying the concrete for the wall, felling timber for the frame and hauling it to a sawmill, to plastering the walls and putting on the trim. Mr. Spicer admits he had his hands full in those days, raising queens and building a house between times. But "all's well that ends well." The young people have a comfortable home overlooking the hills and valleys of northern Jersey. The home has been paid for practically by the bees, which they prize

Speaking of hills always brings to mind springs, and just now the spring where the Spicer household gets water. There are large stones (there is one near there the size of a load of hay) about the sides of the spring, and grasses and bushes. A great maple has its roots just behind; and to complete the setting there are always three solemn frogs sitting guard ready to "plunk" unexpectedly, and make one start.

The little poem by Secretary of Labor Wilson describes it so aptly that a quotation of the opening verse may be allowable. The title is, "To an Old Tin Can."

There's a spring of sparkling water flowing out
beneath the hill,

Where the trees are tall and shady, and the robins
sport at will,

As the breezes, soft and pleasant, in the summer's
sultry heat,

Play about in cooling eddies where the light and
shadows meet,

On a stone within those shadows stands a can of
ancient tin,

With a band of rust about it and a coat of rust
within;

And there's nothing God has given to appease the
thirst of man

Like a cooling draught of water from that rusty
old tin can.

Hoboken, N. J.

SOME INVENTIONS MOTHERED BY NECESSITY

BY A. BUTSCH

After living twenty-one years in the West Indies (just half my life) I can do but little hard work myself. The result is that most of the work must be done by ordinary laborers; and a more awkward and careless set of fellows it would be difficult to imagine. None in the lot can read or write; none of them knows his age. Their perception of right and wrong is about on a level with that of a well-bred fox terrier. With such help at hand, and with the inability of a European to do much hard work, beekeeping on a large scale becomes quite a problem.

Frail devices such as Hoffman frames, Bingham smokers, etc., which in gentler hands work nicely would here crumble away like match-sticks. Even the Cowan automatic had to be overhauled before it could stand the test.

The Hoffman frames were the first I used. They proved too weak. Either the frame came out without the bottom-bar, or the supporting projections or spacing devices would give way. In many cases where a brood-nest had not been taken to pieces for two years I found no other means of getting the frames out than to turn the brood-nest upside down and kick the whole arrangement out "en bloc."

The staple-spaced frames came out a little easier; but the staples are an abomination when extracting. With eight frames in a super the combs get quite thick, and the staples hidden in the honey play havoc with the extracting-knife. If one is prepared to carry a grindstone around in his out-apiaries, and to keep his temper, he may get along with staple-spaced frames; but I think the average beekeeper who extracts between fifteen and twenty tons of honey a year, and means to go to heaven at the end of his laborious beekeeping days,

had better leave the staples out of the business.

This is exactly what I did. To prevent the bottom-bars from pulling out, I made them $\frac{3}{8}$ inch thick and nailed them between the end-bars. The spacing-devices were left out, and the supporting lugs were replaced by a $2\frac{1}{2}$ -inch wire nail. The top, bottom, and end bars were all made the same width, the top and bottom bars being nailed between the end-bars. Now there I had a frame that was extremely simple and quite solid.

FIG. 1.

1, steel plate, 18 gauge, with top edge cut out as shown in Fig. 2, supporting the frames and side-spacing the top-bars; 2, steel pivots supporting frames; 3, steel plate, 18-gauge, cut out the same as 1, but with a notch at 7; 4, steel pivots for end-spacing frames and side-spacing top-bars; 5, wood strip $\frac{3}{16}$ inch thick, holding steel plate 3 in position.

The trouble that now remained was how to space it. Notwithstanding the general

consensus of opinion expressed in the bee-papers I had come to the conclusion that for extracted honey, at any rate, the spacing-device should not be part of the frame, as any kind of spacing interfered with the ease and rapidity of uncapping.

Figs. 1 and 2 show how I got out of the difficulty. I intended at first to patent the arrangement; but although I have taken out several patents in gas and electrical engineering, and even had the rare luck of making some money out of them, I always look with some suspicion on the financial possibilities of a patent in beekeeping apparatus. The sketch sufficiently explains the device.

The frames are here simply thrown in the hives, and they will automatically space themselves. They can be picked out any time without tools. The top-bars can be pushed away from one another for the purpose of looking for brood or queen-cells without taking a frame out. There is practically no chance of killing any bees. These frames can be carted about quite as safely as Hoffman frames; and even with hives only partly filled with frames there is no necessity of doing any stowing away. The hive would cost a little more than the standard dovetailed, but the frames would be cheaper.

Fig. 2.

FIG. 2.

Nos. 1—5, same as for Fig. 1; 6, nail-holes; 7, deep notch in plate 3 and wood strip 5 for holding pivots.

The double groove and wedge proved too refined for West Indian labor. Besides, when the worms eat down the combs, as it often happens in out-apiaries, the wedge and thin strip are invariably eaten out, which makes it difficult to attach new foundation satisfactorily. With the roller shown in Fig. 3 the foundation can be very firmly attached to a plain top-bar in very quick

time. The foundation must be slightly warmed in the sun before putting it in.

Even the ordinary spur imbedder had to be altered as shown in Figs. 5 and 6, where one of the side plates is prolonged and bent at right angles just in front of the wheel and a small notch filed out to guide the wire. With this implement wire can be

FIGS. 3 AND 4.

1, handle (hard wood); 2, wood roller; 3, babbitt metal; 4, steel screw; 5, brass guide; 6, brass screws for attaching guide.

FIGS. 5 AND 6.

1, brass spur-wheel $\frac{3}{4}$ inch thick, $\frac{3}{4}$ inch diameter, 36 pitch; 2, side plate prolonged, and bent at right angle in point of wheel 1; 3 and 4, rivets; 5, small V notch for guiding wire.

expeditiously imbedded, even in the dark, as the roller cannot come off the wire. I use a very thick brass cogwheel with fine cogs without any set, thus firmly imbedding the wire without damaging the foundation.

For the last ten years I have made all my supplies, such as hives, frames, smokers, veil, foundation, shipping-cases, etc., and even an extractor. I own a small machine-shop with circular saws, engine-lathe, boring-machine, etc., with a fair supply of different boring and machine tools. The whole show is driven by a $2\frac{1}{2}$ H. P. gasoline-engine.

It certainly pays to make foundation, whatever Arthur C. Miller may think. With what was worth 20 cents here, and light brood foundation at least 60 cents, there is a saving of \$160 on the first 400 pounds of foundation made. It is true that, in the hands of many, the making of proper foundation is a tedious and unsatisfactory job. It takes some experience, and the instructions sent out with the machines are not worth much.

St. Lucia, West Indies.

THE WINTER CLUSTER

BY MARY G. PHILLIPS

Summer is gone, and the winter drops its mantle of snow
 Gently from clouds of grayness to the dark-brown earth below.
 Now beasts and furry creatures cease from their active play,
 Hunt some quiet hollow where they snugly sleep all day.
 Out by the leafless wood-lot stand the rows of quiet hives,
 Mere undulating snow waves, hiding thousands of tiny lives.
 How peaceful seem those houses! Are the inmates fast asleep?
 Like other tiny creatures, is their dormant slumber deep?

Ah! under the snow-white blanket, all hidden from prying eyes,
 Here life is teeming, bustling, in the row of quiet hives!
 The bees are compactly clustered forming their winter sphere,
 The outside ring is their vanguard to guard against cold severe.
 Each faithful little worker stands at her meted task,
 Fanning, fanning her life out to combat the icy blast.
 Now one leaves the circle to seek the honey store,
 Gathers strength and courage, then back to her work once more.

Brave little honey-workers! Beat, oh beat with all your might!
 Warm the hive and your comrades, it is not always night;
 The creeping chill will vanish, the sweeping wind will die;
 Spring will come with its sunlight! Have courage, then you may fly!
 Washington, D. C.

The first three hives (right to left) are cell-builders; the fourth a honey-producer, and the fifth a mating-box.

BUILDING UP A BUSINESS IN SHIPPING BEES WITHOUT COMBS

Will Wintering Bees Become Obsolete in the Extreme North?

BY W. D. ACHORD

About four years ago I began to ship one-pound packages of bees without queens by April 1, and with queens by April 10. I

find that this size of package is best as early as weather in the North will permit the buyer to receive them. The first year

or two we had considerable loss at times; but last year it was only about 4 per cent or less, while this year it was less than 2 per cent for the entire year. We make our own cages and candy in a way which we find is good for the two extreme conditions—the heat here in April and cold in the North. Perhaps half of these packages go into Canada and all of them north of the Mason and Dixon line.

Judging from reports from buyers I feel quite sure the one-pound package from the South, early in the season, is the most

Two sticks, one black and one white, turned in various directions constitute a record for each mating-box.

profitable way for the northern honey-producer to get his bees. A one-pound colony purchased early, and put on combs and honey, will probably give him, that season, as much honey as the average colony he has wintered over. You see these one-pound packages consist of young worker bees and a young queen, and consequently they are not subject to spring dwindling.

I predict that soon the honey-producer in the extreme north will sulphur his bees in the autumn, and thereby save honey and combs to run one-pound colonies on early in spring. Of course, he can strengthen his weak colonies in early spring with young bees without queens from the South if he dislikes to kill his bees in autumn. He can also use these early swarms from the South to make increase which will give a good surplus the first year. The express charges are from 20 to 40 cents each, depending on quantity and distance.

In 1901 I shipped bees up river into Georgia in June, this being the beginning of migratory beekeeping on this river. In June, 1907, I shipped 300 colonies of bees to Fitzpatrick, Ala. Finding this a good locality for queen-rearing I offered queens for sale. Since then I find that most of the time I have orders for all we can rear.

We now have seven yards in which are a few more than 700 full-sized colonies for the production of bees and honey. We also

A small swarm from a mating-box took up quarters in a pine tree twelve feet above ground. Sealed brood could be seen without molesting the bees.

run about 600 mating-boxes in the spring—some less the latter part of the season.

Yankee mother-in-law, southern husband, Ohio wife, and hybrid children.

Our honey-flow begins about June 10. Our colonies in two-story hives are about ready to swarm the last of March. It is very hard work then to prevent swarming and increase. This, you will notice, is about 70 days before our honey-flow.

Each year I have made enough money to pay my expenses, including those of the family. When I have had short crops I manage to get a higher price per pound than when the crop is large.

In 1899 I went into the bee business ex-

clusively on the Apalachicola River, Florida. Prior to that I was a city man. With a so-called practical men as partner, the first year I lost about \$1000. I then bought the other man's interest and found I had about 200 colonies and a lot of empty hives, etc., including a debt of about \$220. Fitzpatrick, Ala.

[A picture of Mr. Achord's pound package appears on page 981, Nov. 1, and his advertisement elsewhere this issue.—Ed.]

PANHANDLE BEE-PEOPLE TALK IT OVER

BY JOHN RUDE

The Panhandle Beekeepers' Association of Southeastern Ohio and Northern West Virginia, held its semi-annual meeting in the shape of a field meet at "The Lindens," the home of L. C. Seabright, vice-president of the association. To say the meeting was a success is putting it very mildly.

The Lindens is a most beautiful place, situated at Blaine, Ohio, five miles west of Wheeling, W. Va., along the National Boulevard, and is reached by electric car. Mr. Seabright's bees are the yellowest and most gentle I ever saw. Forty-five colonies are all in eleven-frame Langstroth hives of his own design and manufacture. The hives are well made, and have been in use for thirty-

five years. They are practically a double-walled chaff hive, or, better still, a convertible chaff hive, as the ends are chaff packed, and for winter use there is a chaff division-board inserted on each side, four frames being removed. The hives are kept neatly painted and a grapevine grows beside each hive for shade. A well-equipped honey-house and a few fruit-trees comprise the place where beekeepers like to gather.

Crop reports were very poor, but every one reported plenty of swarming. The meeting was short, as the members preferred to move about among the bees, getting acquainted.

Pellaire, Ohio.

There was not one grouch on the place.

Nailing up supers and shallow frames. See Beekeeping in the Southwest, this issue.

THE OHIO STATE BEEKEEPERS' CONVENTION AT AKRON, NOV. 26, 27

BY E. R. ROOT

While the attendance at this convention was not large (not over fifty being present at any one time), it was a representative one, and the discussions were above the average. In the afternoon of the first day the members were piloted through the B. F. Goodrich establishment, the largest rubber-plant in the world—a plant that has 15,000 employees. All who went through expressed themselves as feeling that this was one of the greatest treats of their lives. To see rubber tires for automobiles and bicycles, rubber coats, rubber shoes, and other rubber specialties made, the thousands of workmen like a well-drilled army was indeed a sight. This immense concern opens its doors to the public, and the public is given an insight as to the possibilities that can be accomplished through a great organization.

The first regular session was in the evening, presided over by Mr. Fred Leininger, president. In his address at the opening he called attention to the fact that we were meeting in one of the greatest states in the Union—a state which contains some of the best beekeepers in the world; a state that has the largest bee-supply manufactory in the country if not in the world; a state that sends out more queens than any other in

the Union. While he admitted that the attendance that evening was not as large as that of some meetings in other states, he felt that it represented a large number of colonies of bees. He spoke of the benefits of organization and co-operation; of the importance of getting a better price for our product. The fact that we are not getting better prices he felt was due to the fault of the beekeepers themselves.

He then called on N. E. Shaw, chief inspector of apiaries, Columbus, Ohio, who gave an address on the condition of bee diseases in Ohio. When he first began this work he was somewhat discouraged. Foul brood had taken a tremendous hold, and the task of mitigating its ravages seemed well nigh hopeless; but he was glad to report that many localities that were formerly rotten with the disease were now practically free from it. In many others the disease was becoming less and less prevalent, and it was evident that it would all be cleaned up in the near future.

The report for the year showed a decided gain for the better. About 8000 colonies were inspected last year at an average of 24 cents a colony. This figure, according to Dr. Phillips, who was present, was about normal.

Some discussion followed, after which Dr. Phillips, of the Department of Agriculture, Washington, gave an address on the temperature of the honeybee cluster during winter. He elaborated on the statements he made in bulletin No. 93, a review of which appeared on page 879 of our issue for Nov. 15, 1915.

I will not attempt at this time to give a *résumé*, as the reference given above is much fuller than anything I can give here.

Dr. Phillips was followed by Attorney Melville Hays, of Wilmington, on the subject of bee legislation. Mr. Hays stated that his neighborhood has been having bee diseases ever since a carload of honey was shipped in. To prevent a recurrence of that kind he proposed some advanced legislation. He would require among other things that the consumer burn or disinfect all packages or containers as soon as emptied of honey. He went on to state that when these packages go out on the scrap-heap the bees in the vicinity carry honey that is infected to their hives. He would place authority in the hands of the State Board of Agriculture and give it sufficient power to enforce its provisions.

Most of the beekeepers after the adjournment of the session (it was too late that evening to enter into a general discussion) expressed themselves as feeling that it would be impossible to get through such advanced legislation, and they doubted the wisdom of some of it, because the section requiring the burning or disinfection of packages containing honey would convey to the consumer the impression that such honey was full of germs dangerous even to human beings. Many of them felt that, in view of the difficulty of getting such a law on the statute-books, the present law was quite adequate.

In the morning session the next day Mr. F. W. Summerfield, of Toledo, led off on the subject of migratory beekeeping. Mr. S. is a retired merchant who devotes most of his time to the production of honey during the summer in and near Toledo, and during winter on the Apalachicola River, Florida, a few miles above the famous Merchant location. Mr. Summerfield, who has had a wide experience in moving bees back and forth in car lots, spoke of some of the pleasures and penalties in bringing bees back and forth in car lots. So far he had not made a very great success of it, owing to poor seasons; but neither had he made a complete failure of it. He spoke of the difficulties and cost of wintering bees in the North. He eliminated this by moving his bees south, building them up, taking a crop

of tupelo honey and bringing them back north in two-story colonies. He shipped all his colonies upside down, thus leaving the heavy part of the frames containing the stores against the top-bars now on the bottom. As the bottom-bars now at the top are narrower it gives the bees more room up for clustering.

Mr. Summerfield estimated the cost of taking the bees down and back again, including his own time, at \$2.70 per colony. With ordinary seasons such as are experienced in Apalachicola, and a normal season in Ohio, he felt he could make a good thing of this kind of migratory beekeeping. He doubted very much, though, whether any one could hire some one else to do this and make it pay. In any event, with him he could afford to operate at a loss, as he does not now have to depend on the earnings of the bees to give him a living. The main thing he was after was health and recreation, which he had secured in large doses.

Mr. Summerfield was followed by Mr. F. S. Snook, of the traffic department of the Erie Railroad, Akron, on the subject of shipping honey. Besides being one of the prominent railway men on his line, he is also a beekeeper, and hence he was able to appreciate the problem from the standpoint of the shipper as well as of the carrier. He made it very clear that the policy of his and all railroads, in fact, was to deal fairly with the public; but the public often disregarded the instructions on how to ship commodities, and the average beekeeper was no better. Carelessness in packing has a tendency to advance freight rates. He urged all beekeepers who ship comb honey to ship in carriers of not less than 200 lbs. Smaller shipments, if improperly packed, are very likely to go through in bad order, with the result that a claim would be forthcoming to him for adjustment. There had been comparatively little trouble, he said, from the large shippers of either comb or extracted honey. Most of the claims come from the small producers who have the impression that the railways are soulless corporations that do not care whether the honey is smashed and broken or not. Mr. Snook's address was one that ought to be delivered before the National Beekeepers' Association, and that organization would do well to get a paper from him. It is not often that a railroad man is also a beekeeper.

In the afternoon, Inspector A. C. Ames, of Peninsula, O., in the absence of D. H. Morris, gave a brief report of the exhibit that was made under the auspices of the

Ohio State Beekeepers' Association at the State Fair. He was not able to give definite data, because Mr. Morris, who is now in Cuba, had all the facts and figures.

As a foul-brood inspector he called particular attention to the carelessness of some good beekeepers in the matter of treating foul brood. One man in particular had been melting up his combs in a leaky solar wax-extractor, and wondered why the disease kept spreading through his apiary. Others had been careless in the way they exposed their combs. There was just one thing in the law that he thought ought to be amended, and that was a section that would give the inspector police powers to

compel a beekeeper to transfer his bees into movable-frame hives. So far no special difficulty had been experienced; but the time might come when such authority would be required.

Dr. E. F. Phillips closed with an address on outdoor wintering. He read from his bulletin No. 695, "Outdoor Wintering of Bees," a review of which was given on page 876 of our issue for November 1st. Copies of these bulletins were distributed among the members.

The election of officers resulted as follows:

President, Fred Leininger, Delphos; Vice-president, A. C. Ames, Peninsula; Secretary, Dr. Ernest H. Kohn, Clover Hill, O.

THE HOME-BUILT TRACTOR

BY XENO W. PUTNAM

[On account of illness Mr. Putnam was unable to complete promptly his series of three articles on the Home-built Tractor, the second of which appeared in the first September number.]

A 36-inch drive-wheel moves ahead about eleven and one-third feet for each revolution on the axle. Twenty-five revolutions per minute rolls it forward at the rate of something over three miles per hour. This is quite fast enough for ordinary work around an apiary. If an occasional trip to an out-apiary is necessary this speed may be increased either by increasing the size of any driving-pinion or by diminishing that of any gear-wheel which it drives. Under nearly all circumstances, lower rather than higher speed is needed, because the sudden pitching of a tractor over rough places, added to the continuous vibration caused by the engine, is hard enough at best upon both engine and tractor.

Let us assume that the normal speed of our engine - shaft shown at A, Fig. 1, is 600 revolutions per minute. In the process of transferring this motion to the tractor drive-wheels at H, the revolutions must be reduced to twenty-five or less. An 8-inch sprocket wheel on the engine, belted to a 24-inch wheel on the countershaft B, would bring this speed down to 200 revolutions per minute, because the smaller driving-sprocket would have to make three revolutions in order to

drive the larger wheel through one of its 24-inch revolutions. Our countershaft at B, then, to which the 24-inch sprocket is securely keyed and all that is secured to it along any portion of its length, revolves 200 times per minute.

Between the two sides of the tractor frame we will mount a small gear-pinion on the countershaft. This meshes with the drive rim of the differential shown at C, which is three times as large as the pinion. For every three revolutions of the counter-

FIG. 1.—A, engine-shaft with 8-inch sprocket; B, counter-shaft with 24-inch sprocket and small gear-pinion at center of shaft; C, differential shaft with differential, D, between tractor-sills, and carrying small sprocket wheels (not shown in cut) at each end for belting to bull-sprocket H on the inside of drive-wheel G. Chain between A and B works just inside the chain from C to H between bull-drive chain and sill.

shaft, or every nine of the engine-shaft, the differential revolves once—that is, about 66 times per minute, providing there is no lost motion through slippage. If the tractor is always to move forward, with no reversing gear, the counter-shaft pinion is keyed securely to the shaft. If we wish to provide

for backing the tractor, a keyway must be cut in the countershaft a little more than twice as long as the thickness of the pinion, and a smooth straight key set in securely, so there will be no play. The cutting may be done at home by means of a quarter-inch drill, the series of holes being carefully sunk in exact line for the required depth, and then dug and dressed out by means of a cold-chisel and small files. Drive the key in snugly its full length and then

FIG. 2.

slip the pinion upon the shaft with the keyway dressed out to slide easily upon the key but without wobble. To the pinion must be attached a shift-gear collar such as can easily be secured from a mowing-machine or almost anything else with provision for shifting a gear-wheel. Frequently a pinion and collar cast together can be secured.

At each end of the differential shaft we now fit a sprocket-wheel that will work on a chain of the same number required for the bull-sprocket on the main drive-wheel of the tractor described in the last number of this series. Both of these small sprockets must be alike in size, and preferably both should be mates of the large sprockets in the same binders; then there will be no question about everything working properly and in absolute step. For instance, if we get our two drive-wheels out of two old Champion binders, and at the same time secure with each the small sprocket over which the drive-chains worked, we are sure of avoiding possible trouble through some little difference in the pitch of the two wheels. If these sprockets are one-third the size of the bull-sprockets we have our speed divided by three again, and so get the drive-wheel rate of revolution down to 22 per minute, which will be found fast enough. If the difference between this last pair of wheels is greater or less than three to one, we must vary one of the other pairs of gears a little to suit the occasion, unless we are able to change the speed of the engine or remodel our own ideals as to speed. In making any variations it should always be remembered that it is better to increase the size of the driven wheel rather than to decrease that of the driving pinion, because there is more tendency to cramp and bind in the smaller diameters of wheels. This rule holds good alike with gear and sprock-

et wheels, and, for heavy duty, the wheel that gets below twelve to fifteen teeth must be considered in the light of a necessary evil which should be avoided as much as can be without too greatly increasing the size of the larger wheels.

By connecting the sprocket-wheel on the engine with the countershaft by a chain, and attaching the two sprocket-wheels on the differential shaft to the two drive-wheels of the tractor in the same manner,

FIG. 3.

we now have in Fig. 1 a tractor that would move forward in a straight line whenever the engine is running. To crank the engine, however, we would have to move the entire tractor, while there could be no gradual picking up by the engine of the load and no variation of speed. It would be almost impossible, too, to change direction, because both of the tractor drive-wheels would be driven forward directly from the engine at equal speed. We could not turn a corner without sliding the wheels, and would find the tractor very hard to handle on rough ground.

The differential permits one of the drive-wheels to turn faster than the other, and one of some sort should by all means be used. One from a worn-out steam-tractor is occasionally available at junk prices, though generally the differential is pretty well worn out by the time the rest of the rig is useless; also it is pretty heavy for a light tractor. At a very small cost an automobile differential of some sort can generally be obtained of any garage or second-hand automobile shop, though often these are pretty well worn. They answer quite well, when in fair repair, for a tractor up to about ten-horse power. The entire shaft should be purchased together, and mounted in the place shown for the differential shaft, and then cut to length. Probably a sprocket-wheel will have to be substituted for the gear-pinion on the countershaft, and a chain-drive be used between the latter and the differential.

FIG. 4.—This double-gear wheel turns upon its shaft, which need not turn. The relative speed of the forward and reverse motion of the tractor depends upon the relative size of the two members.

There is a complete and very fine differential set on the market which may be purchased new for about \$18. Very small tractors made with mowing-machine drive-wheels may be provided with a fairly good differential by retaining the compensating gearing in the case about the hubs and reversing the wheels. The differential problem can also be gotten around by building a three-wheel tractor, with but one wheel behind, and that the drive-wheel. One good heavy binder-wheel gives a pretty good ground grip that will take a light tractor over most places about an apiary.

FIG. 5.—One of the two sprocket-wheels here shown should be replaced by a clutch-pulley, and the sprocket attached to the loose member of the pulley.

A regular tractor differential with gear-drive rim is shown at Fig. 2 and a sprocket drive differential at Fig. 3. The ends of the shaft upon which this is mounted project beyond the frame into line with the bull-sprocket wheel, and the small sprocket at the one end is keyed to the shaft and on the other to the sleeve which is a part of one bevel-gear wheel in the differential, and which runs loosely upon the shaft. Small tractors are sometimes built with drive-chain to but one of the bull-wheels. Then no differential is needed as the free wheel can do all the work of adjustment in turning. On rough ground, even though one gets into difficulty, if the one driving-wheel happens to drop into a hole, or where there is poor footing, its mate is not harnessed up to help it out. The single drive-wheel, too, unless placed in the center, puts a constant diagonal strain upon the whole tractor.

The reversing gear is simple—just a double gear-wheel shown in Fig. 4, and mounted loosely upon a shaft under the countershaft pinion with which its larger member meshes when the sliding pinion of the countershaft is slid to one side out of mesh with the differential drive. The small member of the double gear is constantly in mesh with the under side of the differential drive. When the countershaft drive-pinion is also in mesh with the reverse gear, and the latter runs as an idler, receiving its motion from the differential through its small member. The differential then is running in the di-

rection opposite from the countershaft, and the reverse gear turns in the opposite direction from the differential or the same direction as the countershaft pinion, which it does not touch. All meshing gear-wheels, it is to be remembered, run in directions opposite from each other. When the counter-shaft pinion is slid out of mesh with the differential, and into mesh with the larger member of the reverse gear, the latter is driven by it in the direction opposite from that of the pinion, and, in turn, through its smaller member, drives the differential in the direction opposite from itself or in the same direction as the countershaft. This reverses the direction of the tractor.

If there is a clutch-pulley on the engine, no other will be needed on the tractor, the drive-sprocket of the engine-shaft being secured to the loose member of the pulley. Then the clutch can be thrown out and the engine started in the usual manner; and, after it is running, the clutch can be gradually thrown in. Without a clutch on the engine one must be placed upon the countershaft, where the large sprocket is shown in Fig. 5, and the sprocket attached to the loose member of the clutch. A very good light clutch-pulley can be purchased for \$10; or, if one does not wish to go to that expense, a belt drive can be substituted for the chain drive between engine and countershaft; then by means of a loose belt and tightener the load can be thrown off and picked up very nicely. This drive is not as sure in wet weather nor on bad roads nor under a heavy pull. Sometimes one avoids a breakdown by the hitch between load and engine not being too unyielding.

FIG. 6.—By using the old bolt-holes and bracing to frame of casting, an absolutely true and rigid set of bearings can be obtained.

The shafting for this tractor may all be found in old binders and mowers, as good as new. Nearly always the main shaft is $1\frac{1}{2}$ inches. Where possible to accommodate the gearing to it, by all means retain the cast boxings and frame, or as much of them as is necessary to secure a good unyielding anchorage for the shafts. A frame such as shows at Fig. 6 may require a little more room but will not get out of alignment, and is easily secured to the tractor frame by means of the bolt-holes and the irregularities of form against which bracing can be

fitted. Some of this casting might be cut away with a hack-saw or file so as to accommodate the gear pinion and the long key-way without destroying the opportunities for fastening it to the frame. Often the success of the tractor depends quite as much upon correct alignment and perfect rigidity as on the selection of the parts and their general arrangement.

This completes the running members of the tractor, and leaves for another paper such conveniences as the steering gear, engine control, and a variety of necessary trimmings, together with a few words regarding some of the more useful special attachments needed upon the ideal tractor for the apiary.

Harmonsburg, Pa.

AN OFF YEAR IN CUBA

BY FRANK REIMANN

Conditions for several years have been unfavorable. Perhaps this accounts for no articles from Cuba. In the United States a real good crop is expected only once in twenty years. In Cuba it is about once in five years. For instance, 1500 hives of bees in an extra year will make 400 barrels of 50 gallons each. In a poor year they would make from 100 to 200 barrels a year. The smallest crop I had in ten years was 100 barrels. The cause of the poor years may be a dry summer or cold winter, or both. The last week of October and November were so cold that the bees made very little honey.

This summer where I had the majority of the beeyards it was very dry, only about five inches of rain fell. Sixty inches is not an extraordinary rainfall for Cuba for a year. I have only one beeyard that was in condition to make a full crop, and this will not be over three-fourths now, on account of the great drouth and cold.

Owing to the low price of extracted honey on account of the war, last winter I purchased 10,000 sections in the United States to raise comb honey this year. By this time I have been working in 250 supers, and I think these sections will be all completed by Christmas. Our main crop, campanilla, is now on. I am using three beeyards to fill these sections, whereas in a good season one yard would have filled them.

The strained honey has now advanced to 35 cts. a gallon, which is considered good business for Cuba. Our honey business in Cuba is almost entirely with Germany. Four years ago we had a very large crop with high prices. This induced quite a large number of natives to go into the business. Now with three bad years they all want to sell out, and I buy these bees at my own price. Their bees are near the mountain near Yara, where I shall be located in the future. My business between Cauto and Guamo I expect to sell or rent.

There is help in abundance here. In the honey season we extract one beeyard a day. I have one man to take the honey from the hives, one to take the honey into the house and bring the empty combs back; two women to uncap, one man at the extractor, one woman to cut out the drone or old combs, and one man to put the combs back in the hives. In this way we can extract a barrel an hour.

The beeyards have between 200 and 300 hives. I find that 300 lives should be the limit in one yard here. I pay the men \$1.25 a day, and the women 50 cents.

The honey business is in a decline in Cuba. As a beekeeper makes his money from bees he finds other opportunities that will pay more money. For instance, in the cattle business a beekeeper can buy a cow here for \$25 to \$30. In a year he can raise a male calf which will bring \$20, and a female will bring \$15. In a few years we can have a very substantial way to make a living. I know various beekeepers who began here about fifteen years ago have now large cattle-ranches all paid for. Sugar-cane is getting the best of the beekeeper. Wherever a new sugar-mill is started the beekeeper must move on, as our principal source of honey is the woods.

A person intending to locate in a foreign country should pass some time with an expert beekeeper, because climates are different, and from the natives it is impossible to learn.

We have honey here all winter; but in the summer we have our bad seasons, and at the same time these bad months may give a surplus of honey. One beeyard gave twenty-two barrels last summer, and this summer he has made only two barrels.

I kept bees in different parts of the United States for twenty years, and had only two good seasons. Surely there is no year here when one could not make a good living in the bee business in a good locality.

Cauto el Paso, Cuba.

Heads of Grain from Different Fields

The Backlot Buzzer

BY J. H. DONAHEY

It's a good thing she's a bee or the mother queen would lose her patience taking care of her flock when they are all tucked in for the winter. Remember how you used to yell, "Mother, make these kids behave; they've got all the covers"?

Did They Stop Laying for Want of Pollen?

Having ten years' experience in handling bees I have never experienced a scarcity of pollen at this time of the year. I have noticed for the last six weeks or more that my queens—all young ones—stopped laying. I also tried to force them by feeding, and that had no effect. It was only last week that I came to a decision on the pollen question.

I should like to have you tell me the reason the queens stopped laying if other than that there was no pollen in the hives, and also how to save them till spring, as I do not care about losing a single queen. All are of good stock, there being sixteen in all. I had thought of packing all in large single-row tenement hives with six inches of leaves or shavings around the outside of the hives, and filling one comb solid with rye flour and putting it to one side of the cluster to form a division-board.

Philadelphia, Pa.

SAMUEL K. JOHNSON.

[As a general proposition, all queens will stop laying, whether young or old, by about the first or middle of October. Old queens will stop laying shortly after the harvest in most of the northern localities. Much will depend upon whether there is a fall flow from asters or other sources. If honey comes in from natural sources queens will start laying and will keep it up until about the 15th of October, or about the time that cool nights begin to come on. Young queens—that is, queens 30 or 60 days old, will lay very much better than old ones.

Perhaps your trouble was because you began feeding too late. If the nights are cool, queens don't lay much—pollen or no pollen.

In the case you have here cited, it is not altogether clear that a lack of pollen was the reason for the queens failing to lay. As a general thing there will be a little pollen in some of the combs in the hive; and if the bees are given stimulative feeding, if no honey is coming in from natural sources, queens will usually start laying, providing they are young enough. Old queens may not lay, even if they are fed, at that time of the year.

Your scheme of packing in long rows is good; but if your colonies are not strong you will have to unite until they are. This may mean the sacrifice of some queens.

We do not know of any way of giving artificial pollen in the combs that will give any satisfactory results.—ED.]

Devil's Paint-brush, or Orange Hawkweed

I should like to find out about a weed we have here. It is an annual, and is known as "Devil's paint-brush," or orange hawkweed. The pastures, old meadows, and roadsides are red with it the last two weeks in June, and the bees seem to like it better than clover. The pollen is a dark-orange color, and the honey water-white and quite heavy and thick. I have been unable to find a single fact about the weed. Can you give me any information?

Laurens, N. Y.

C. L. WILLIAMS.

[We referred this inquiry to Mr. John H. Lovell, who replies as follows.—ED.]

Orange hawkweed, "Devil's paint-brush," or "Grim the collier," was introduced into this country from Europe some fifteen or twenty years ago. The botanical name is *Hieracium aurantiacum* L. It is a pernicious weed, rapidly spreading in sandy soil, and driving out the pasture grasses; but the flowers are showy, and it is sometimes, I believe, cultivated for ornament. I have it growing in my grounds, and it occurs wild in the fields, but is not well adapted to our heavy clay soil. Bees visit it to some extent—chiefly, I think, for pollen, and I regard it as of little value as a honey-plant. It may yield nectar more freely, possibly, in New York, but I am inclined to believe that Mr. Williams is mistaken in thinking he obtained a considerable quantity of water-white honey from this source.

Waldoboro, Me.

JOHN H. LOVELL.

Concerning the Net-weight Law

I should like to ask you some questions concerning the net-weight law. Is it necessary to stamp the net weight and label each $\frac{1}{2}$ lb. (6 $\frac{1}{2}$ oz.) tumbler of extracted honey, or stamp the net weight or label each $\frac{1}{2}$ -lb. tumbler when shipped to Ohio, or just stamp the net weight, or label each case or barrel of them as the case may be?

Brooksville, Ky.

ADAM KALE.

[It will be necessary to mark the net weight on each half-pound package of honey. Marking the net weight on each case or barrel would not answer the requirements of the federal law. If each package of honey weighs 6 $\frac{1}{2}$ ounces it will not be proper to mark it one-half pound. If the honey weighs only 5 ounces, for example, it will have to be marked 5 ounces; but it would not be permissible for you to mark a package 17 ounces, because that would be contrary to the ruling. You would have to mark it 1 lb. and 1 oz. Any thing that weighs under one pound should be marked in terms of ounces.—ED.]

Spreading Brood

For years I have followed with excellent results the advice of Doolittle on spreading brood. My rule is never to spread a brood-nest till I have four combs of brood. Why? Because there are not enough bees to cover extra brood space. I never shift the pollen combs, for they are as important to the welfare of the colony as the honey. My arrangement is as follows:

Pollen
Brood
Brood
Old comb filled with honey
Brood
Brood
Pollen

P. C. Chadwick, page 883, November 1, quoting Mr. Doolittle, who says, page 750, September 15, "Any comb that is to be put between combs of brood should be full of honey, and that honey preferably sealed, adds that he would thank no one for retarding the work of his queen in any such manner. He says spreading brood should never be done unless conditions are such as to induce the queen to fill an inserted comb in 24 to 48 hours.

Mr. Chadwick's comment is misleading. Doolittle does not mean the honey is to be sealed when inserted in the hive. What he undoubtedly means is a well-ripened comb of honey, for he says further on, "The cappings to the cells should be broken by passing a knife flatwise over them before the comb is inserted between the frames of brood."

What happens when an old comb of bruised honey is given to a colony of four combs of brood and two of honey? The bees at once set to work to clean up the bruised honey; and in moving the honey the queen is offered more food, with the result of more eggs. Meanwhile the bees have been busy polishing and cleaning the center frame, leaving an arc of honey ideal to the bees for an early brood-nest. The old comb with its numerous layers of cocoons is warmer than a thin new comb, and retains the animal heat—vital to the interests of the brood-nest at this time of the year. The four combs of brood are daily giving more nurse bees necessary to take care of the increase of eggs, etc., and, as Doolittle says, there is undoubtedly a gain in time, but unless we want this gain in time it may prove better to see to it in autumn that there are "millions of honey at our house," and leave the rest to the bees.

JOSEPH GRAY.

A Simple Four-colony Winter Case

Here is a description of a winter case which Irvin Ware, of Chesaning, Michigan, a partner of mine in the bee business, built for our bees. I helped to pack them before I came up here this fall.

First he makes a bottom-board about eight inches longer than the length of the hive, and then makes sides and ends about four inches higher. These are all put together with clamps. This gives four inches room for packing on both sides and ends, and over the top.

There is an alighting-board six or eight inches wide. Slats half an inch thick are nailed on the bottom-board, and the hive rests on these. A four-inch board laid flat on these slats at the front of the hive holds up the packing material and permits the bees to pass in and out.

When the hives were all packed, and the cases clamped together, we covered them with tar paper. With this kind of winter case we can leave them packed just as long as we wish in the spring, as they rest on these stands winter and summer, the bottom-boards resting on blocks and stones.

These colonies winter facing eastward, on the east side of ten acres of a thick wood. There is a little rise in the land just east of the bees that

protects them from the east winds, and the wood protects them from the west. I have never noticed much trouble from the bees drifting.

Aitkin, Minn.

WILLIAM CRAIG.

The Net-weight Law and Its Application

Have you a copy of the net-weight law of New Jersey? If not, where can I get it? The groceries here are selling honey without being stamped. I have told them it will have to be stamped, and they say, "No, we don't sell it by the pound. We sell it by the box." Now, have they a right to sell it that way? Whom can I write to, to stop it?

Monroe, N. J.

JOHN K. KIMBLE.

[Unless your own state has a net-weight law of its own, independent of the federal law, the grocer is not compelled to mark the net weight on the section, neither is any local beekeeper. But any grocer or beekeeper, or any one else, in fact, who attempts to send a shipment of comb honey into another state must mark every section with the minimum net weight on the section itself.—Ed.]

Onion Juice a Remedy for Bee-stings

I am curious to know whether anybody besides our family and friend have ever tried onion juice as a remedy for stings. Our experience has been this—that if the sting is immediately and carefully removed, and if a slice of raw onion is gently pressed and worked over the punctured skin, all pain ceases in about ten minutes, and little or no swelling follows. The relief is immediate.

If a small piece of ice is put on the slice of onion, and the whole bound to the affected part with a strip of cloth, the effect is even better; but ordinarily a drop or two of fresh juice squeezed from the onion slice will do the business with me, if the application is immediate. I am curious to know what others have to say about this cure for a bee-sting. The whole credit for the cure belongs to my wife.

J. ROWE WEBSTER.

Lexington, Mass.

[Any cooling application, whether it be snow, ice, mud, a wet rag, or slice of an onion, would tend to relieve the pain from a sting. The pain will usually be gone in ten minutes any way. We doubt if there is any virtue in the juice of an onion itself. As a general thing the puncture made by a sting is so very minute that it is entirely closed when a slight swelling takes place. It is practically impossible to get any remedial agent into the wound itself unless it be opened with the point of a lance or knife.—Ed.]

Borax Exterminates Roaches

When I took charge of the Kanawha County Infirmary the kitchen, dining-room, toilet-rooms, and the whole building, as well as the superintendent's residence, was creeping with roaches. I took powdered borax, sprinkled it along the steam-pipes, around the sinks and commodes, from the basement to attic. In two weeks not a roach was to be found, either dead or alive, and they have not returned to this date. The roaches had been in the buildings for ten years.

Hornets Puncture the Grapes and the Bees Suck the Juices

Referring to the editorial in the November 15th issue, I have been watching this matter very closely, and find that hornets, wasps, and yellow-jackets often puncture the grapes, and then the bees get busy on the damaged fruit. If I were on a jury I would say that bees are not guilty, for they are harmless so far as sound fruit is concerned.

OUR HOMES

Editor

THE WAR, AND ITS EFFECTS ON INTEMPERANCE.

The sermon below was preached by Rev. H. S. Fritsch, for his congregation here in Medina, on Sunday evening, Oct. 10. Of course I was present, and, on account of my deafness, I sat close to the speaker. You may be sure I gave two or three hearty amens. As you go along you can imagine, each of you individually, where my amens occurred.

May God help us to learn speedily the lesson he is striving to teach us, and that peace and good will may take the place of death and devastation.

SOME LESSONS THAT THE EUROPEAN WAR IS TEACHING THE WORLD.

Surely the wrath of man shall praise thee.—PSALM 72:10.

The most significant event of modern times is the war now being waged in Europe. It is the duty of the Christian pulpit to interpret the movements and happenings of the day in their relation to the Christian religion.

In our boyhood days, when we were guilty of some particular piece of folly our elders used to philosophize for us and say, "Let it be a lesson to you!" If we climbed up on the woodshed in order from that lofty height to survey the wide expanse of the world, and lost our equilibrium, and rolled gracefully and disgracefully down the shed's sloping roof, landing upon the woodpile below with various and sundry bumps and bruises, our elders would say, "Now let this be a lesson to you!" If we banqueted in the shade of the old apple-tree, following the example of our illustrious first forefather who tasted the forbidden fruit, and then came into the presence of our elders contorted out of all semblance of boyish shape, imploring for a copious draught of Dr. Perry Davis' Pain Killer, we were told, "Now let this be a lesson to you!" If within our breast we felt surging and seething an impulse to devote ourselves to the great cause of humanity, and, following our Napoleonic and Alexandrian impulses for conquest we sallied and sailed forth to reduce the barbarians to civilization, and returned to our parental home with blackened eye and gory nose, we were told, "Now let this be a lesson to you!"

Nations, like boys, learn by experience. Nations, like boys, too, perpetrate their follies. The perpetration of a folly is not so reprehensible; it is the perpetuation of a folly that is criminal and suicidal. Nations, like boys, decline and degenerate when they do not permit their follies to teach them salubrious lessons. Nations, like boys, progress and advance when they do permit their follies to become lessons.

To every unprejudiced mind the European War appears a colossal and consummate piece of folly. Never before in the history of the world have the nations raged and the kings of the earth set themselves in battle array without knowing what they were raging over or why they are setting themselves in array! Were it not so tragic, one might say, as the Yiddishers do. "It is to laugh!" "He that sitteth in the heavens shall laugh!" A colossal, a consummate human folly is this modern war! The nations climbed the woodshed of arrogant materialism, and have tumbled disgracefully down! They gorged themselves with the forbidden fruit of land and sea grabbing, and have become contorted by

painful convulsions! They adopted political programs of militarisms and navalism, and have become bruised and broken and battered and beaten at their own game! Folly of follies! And over against the war-racked and war-wrecked nations stands parental Christian Civilization and says, "Now let this be a lesson to you!"

What the ultimate and supreme lesson of this war will be, we have no way of knowing until it has been fought out to the bitter end. But there are already several lessons which stand out, and it is these of which I wish to speak tonight.

I. I think that, above everything, the present war is teaching the world the lesson of the *folly of intemperance*. Today in practically all of the great belligerent countries is a literal fulfilment of the prophecy of Joel, chapter 1, verses 5 and 6:

Awake, ye drunkards, and weep; and wail, all ye drinkers of wine, because of the sweet wine; for it is cut off from your mouth. For a nation is come up upon my land, strong, and without number; his teeth are the teeth of a lion, and he hath the jaw-teeth of a lioness.

"Not Germany," recently said a great English statesman, "not Germany, but alcohol, is England's greatest enemy." Russia put the ban on vodka. The kaiser of Germany took his stand against lager beer, and all of the other belligerent nations to a greater or lesser degree are following the footsteps of these three illustrious examples.

It has been brought home to the world with a terrific and tremendous emphasis that intemperance is a threefold liability to a nation at war.

1. Intemperance is a *physical liability*.

The time was when athletes believed that alcohol constituted a physical asset. The prize-fighter took a number of drinks before he entered the ring, because he believed that the stimulant would increase his chances for success. The baseball player believed that whisky was a faithful ally in the winning of the game. In races, whether by foot or boat or bicycle, it was believed that a couple of drinks increased the chances for success. But the athletic world has learned its folly, and alcohol is taboo.

So, also, it used to be thought that alcohol was an asset in war. Perhaps this was true to some extent in the old *régime*. It may have been in the day when men fought shoulder to shoulder with sword or bayonet, that whisky created a certain frenzy of abandonment which may have had its value. But today warfare is largely conducted by machinery, and requires skill and precision. The man who operates the modern engines of war needs clearness of mind and accuracy of eye and steadiness of muscle; and it has been discovered that alcohol is tremendously treacherous in these respects.

The talk of our nation today is military preparedness. I shall have something to say concerning this a little later, but just here beg to say that I fear our statesmen are beginning wrong end to. The very best move that our nation could make in the way of national preparedness would be to close up every saloon in the country!

2. Alcohol has proven to be a *financial liability* in war.

War costs money. It is a drain upon the property and prosperity of the people. Intemperance produces poverty. An impoverished nation finds it hard to secure credit. "The nation that is drunken shall come to poverty," and a poverty-stricken nation stands no show in warfare.

3. Intemperance is an *economic liability* in war. Let me illustrate what I mean by citing Germany and England as examples. Both of these nations have far more people upon their soil than the prod-

acts of their soil will feed. Therefore they must depend for their existence upon the importation of foodstuffs. England knows that this is true of Germany, therefore England established a blockade around Germany to keep foodstuffs from reaching her enemy. Germany knows that this is true of England, therefore Germany conducts a submarine warfare of destruction against vessels carrying foodstuffs to England. This makes it necessary that every ounce of grain raised in both countries be carefully conserved. Now, in spite of the alluring advertisements of brewers and distillers, the food value of beer and whisky might just as well be burned or buried. In order to protect themselves from sheer starvation, it is becoming necessary for the belligerent nation to prohibit the destruction of grain by forbidding or limiting the manufacture of alcoholic liquors.

So intemperance is proving itself a terrible liability in warfare. It makes the soldier incompetent and inefficient, it impoverishes the people so that they cannot bear the financial strain of the war tax, it destroys the products of the soil so that the people are in danger of starvation. No wonder that the great belligerent nations of Europe have latterly become ardent prohibitionists! God grant that America may learn the lesson before it has to be beaten into her with the sword!

II. The war is also teaching the world the *folly of armaments*. The world is learning the truth of the statement long ago made in the 33d Psalm, verses 16 and 17:

There is no king saved by the multitude of a host: a mighty man is not delivered by great strength. A horse is a vain thing for safety; neither doth he deliver any by his great power.

A horse is a vain thing for safety, so is a trench, so is a Krupp gun, so is a battleship, so is a zeppelin.

It is not in the province of the pulpit to take one side or the other in the present discussion of preparedness in our country. That is rather a political question, and must be fought out by the politicians. It behooves every American, however, to consider how much of the present agitation is jingoism and how much of it is inspired by the big interests who have guns and uniforms and battlehips for sale. But there is a deep philosophy of this whole question of preparedness which is truly in the province of the pulpit, and it is the philosophy of the text that I have just quoted:

There is no king saved by the multitude of a host: a mighty man is not delivered by great strength. A horse is a vain thing for safety, neither doth he deliver any by his great power.

Why is a horse a vain thing for safety? Simply because the other fellow will get a horse too, and then you will have to get two horses; then he will get two; then you'll get three horses; and he'll get three also. Then you will get a chariot to hitch to your horses; and he will hitch his horses to chariots. You will build a battleship, then the enemy builds a battleship just a little bigger than yours. Then you must throw your battleship upon the scrap-heap and build one bigger than his. Then he will throw his battleship upon the junk-pile and build one bigger than yours. Verily, a battleship is a vain thing for safety.

Why is no king saved by the multitude of a host? Because the other king will also get a bigger multitude of a host, then the first king must draft more men into service; and the second king, discovering that his host is now comparatively a handful, drafts still more men into service. And thus the process goes on and on.

The present European War is surely going to teach the world the lesson that every armament is a vain thing for safety.

Universal disarmament is coming, not by the

efforts of those who do not believe in war, but by the machinations and manipulations and maneuvering of the warriors. "Surely thou makest the wrath of man to praise thee," and disarmament is coming by the very efforts of those who advocate armament!

This is the way the process will work itself out: battleship after battleship must be thrown upon the scrap-heap as each nation in turn builds a bigger or more effective ship; cannon after cannon must be consigned to the junk-pile as each nation designs a more effective instrument of slaughter. The process will go on draining the treasury of the nation and emptying the purses of the people until there will be no men left to cultivate the fields and do the nation's work, and in sheer self-defense the nation will have to send its soldiers home.

But this disarmament will not take place next week, nor yet next year. For some time to come, at least, the nations now engaged in warfare will manufacture more and more armaments and draft more and more men into service. Inevitably the neutral nations will feel, in self-defense, that they must do likewise, and doubtless this is the part of wisdom. If a bunch of hoodlums were clubbing each other on the street, the innocent by-stander would be foolish not to supply himself with a club for self-defense should the hoodlums attack him—though perhaps he ought not to be an innocent by-stander. He'd better be a by-walker and leave the hoodlums to club it out among themselves. But it would be folly for America not to make some provision for self-defense should the maniacs across the waters get after us. So it will inevitably come about that there will be an increase of militarism, not only in America but in all the neutral nations of the world. But all this will be but transient and temporary. When the war is over, and the tumult and the shouting shall have died, and the hatred and the heat shall have cooled, then the nations will settle down and calmly consider the whole matter, and it will inevitably follow that there will result international disarmament, because the nations will have learned by bitter experience the truth, long ago spoken by divine inspiration, that armaments are vain for safety.

III. Of chief importance, however, is the third lesson that will surely be learned, the lesson of the *folly of theoretical religion*.

This war has been called the "collapse of Christianity." It is not the collapse of Christianity, but it is the collapse of a false Christianity. It is not the collapse of the Christianity that Jesus taught, but it is the collapse of the Christianity that the church has taught.

It is a significant fact that in all of the belligerent countries the progress of the war has been marked by great religious revivals. Superficial observers clap their hands at this and say, "Behold, there is at least some good coming out of this war. Behold the revivals that are taking place." But before they clap their hands too vigorously it might be well to investigate just what is being revived. In Germany there is a great revival of prayer. So far so good! But what is the burden of the prayer? "Gott strafe England!" "God punish England! God punish England!" In England there is a great revival of religion, and the squabbles which have disturbed the theological circles over there are quite forgotten in the unity of consecration; but, alas! it is a consecration to hatred! There is a revival of religion in the belligerent countries, to be sure, but it is not the revival of the religion of Jesus Christ, but of Joshua; not of Calvary, but of Canaan!

This revival of traditional religion is as inevitable as the revival of armamentation which we have just noted. But when the frenzy of hatred is cooled down, and the Christians of the various countries come together again in council, they will begin to ask themselves, "Why was it that our Christianity did not have power enough to keep us from fighting each other?" And, as surely as there is a God in

heaven, the answer will be that it was because our Christianity was not Christian!

The simple religion of Jesus Christ has been perverted into a system of theology. Forms and formulas, rites and rituals, creeds and confessions, organs and organizations, signs and sacraments, have been substituted by the church in place of the simple ethical philosophy of the Sermon on the Mount. The accepted orthodox Christianity of the day could not and would not prevent the European War; but the Christianity of the Sermon on the Mount, epitomized in the Golden Rule, could have and would have prevented the war. And surely in those calm days which are coming after the conflict, there will be a revival of real religion. Forms and formulas, rites and rituals, creeds and confessions, organs and organizations, signs and sacraments will be thrown on the scrap-heap, and the Golden Rule of Christ will be placed upon the moral throne of the world! Already here and there above the shouting and the tumult there is heard the voice of the prophet speaking in the language of ancient Micah:

Wherewith shall I come before Jehovah, and bow myself before the high God? Shall I come before him with burnt-offerings, with calves a year old? Will Jehovah be pleased with thousands of rams, or with ten thousands of rivers of oil? Shall I give my first-born for my transgressions, the fruit of my body for the sin of my soul? He hath showed thee, O man, what is good; and what doth Jehovah require of thee, but to do justly, and to love kindness, and to walk humbly with thy God?

O foolish Christian church! let it be a lesson to you! Your traditional orthodoxy has been weighed in the balances and found wanting! Shamefully powerless have your creeds and confessions proven themselves in this world woe! Away with your impotent theoretical theology, and enthrone the potent teaching of the Master:

Whosoever ye would that men should do unto you, do ye even so unto them.

Thou shalt love the Lord thy God with all thy heart, and with all thy soul, and with all thy mind, and thy neighbor as thyself.

CAN A CHRISTIAN WITH A CLEAR CONSCIENCE GO TO WAR?

The letter below is from an old and valued friend. As you will notice by the date, it came some time ago. Read it and ponder over it as I have done.

Dear Friend:—This is from the father of Wesley Foster, who used to read with delight and profit the old *American Bee Journal* and Novice's articles. Pardon me if I suggest a few thoughts that seem important at the present time. The worldwide war still rages, and Christians of all these nations have no clear and effectual protest or explanation, nor any remedy to offer. For nearly 50 years I have been led to think the gospel remedy is not in itself at fault. We have all adopted the sentiments of the sermon on the mount; but in our practice we have set it at naught—made its vital force void by our traditions of patriotism—our law-and-order ideas and our military sentiments. We have vainly supposed that men would, by and by, put up the sword; but to-day scarcely a man in a million dare confess his belief in a gospel that forbids war. There is *no conscience* regarding the taking of human life in war. We hear no testimonies to-day like those of early Christians who declared, "I am a Christian; I cannot fight. I cannot fight, even if I die."

I can think of no stand that we could take to-day which would be more pleasing to God and our Savior than a calm, persistent refusal to take any part in the bloody conflict now raging. Such counsel may appear foolish, coming from a grandpa who is too old to be in the ranks. But why should our extreme age exempt us? We have lived long; our race is nearly run; our lifework is about finished. The world can better spare us than the young men with growing families. Surely it is wrong for any nation to call such citizens to the ranks of slaughter. God never intended to bless such a murderous sacrifice. Surely a young man may claim a right to fulfill his mission by building a home and leaving a goodly number of his little ones to bless the world. Don't tell me we are to obey rulers when they call to arms. Rather let us say in faith, "Whether we ought to obey God or men, judge ye." See Acts 4: 19. For nearly 2000 years we have tried profession without practice; but now it is up to us to practice what we profess, and give God a chance to work miracles by protecting his own, even those who are willing and obedient. Some of our heroic missionaries take their lives in their hands and work wonders until the merchant ships land their traders, backed by warships, and military ideas creep in and sow seeds of distrust, and the pure gospel of peace becomes tarnished.

What of the cross of Jesus? Even when the mob crowded about him he could have called for legions of protecting angels for himself and his cause (this last more dear to him than life); but he chose rather what we to-day cannot fully understand—that the weapons of our warfare are not carnal but spiritual.

You and I should have some timely counsel to offer our children, even true words—"wisdom from above," the kind that is "first pure, then peaceable." Has not the experience of years shown us the value of the gospel in all the lesser evils? and are we not called upon to declare our belief that, when rightly applied to this age-old wounds of the nations it will cure that also! We shall not see the triumph of Christ until his followers cease their present-day hypocrisy. We must, regardless of what others do, live, practice, and teach what Jesus taught, and was willing to lay down his life for. Martyrs of that sort are not many, but are notably such as do not die fighting with the weapons of war in their hands.

Twin Falls, Ida., Nov. 28. A. F. FOSTER.

After reading the above I feel strongly inclined to stand by our good brother and say, "I cannot consent to raise my hand against my fellow-man," or declare, "I am a Christian. I cannot fight, even if I die." But when I consider further, how about defending the home, the wife, and the children? I have before asked the question if we should knowingly let counterfeits ply their trade; and the same with pickpockets, highway robbers, and the midnight assassin? After every earthquake or flood there are in every city those who would plunder, rob, and steal. Shall we stand idly by where the officers of the law and policemen are nearly overcome while doing their best to restrain a mob? I leave our readers to judge; and may God in his great mercy guide us in the straight path, even if this war *should* come clear over into our own country.

HIGH-PRESSURE GARDENING

SWEET CLOVER—SOMETHING AUTHORITATIVE
BECAUSE IT COMES FROM THE DEPART-
MENT OF AGRICULTURE.

In the *Weekly News Letter* from the Department of Agriculture for Sept. 15 we find an article on sweet clover, which, even though it be lengthy, answers so many questions that keep coming we have decided to give it entire; and I would advise our readers who are interested in experimenting with sweet clover to keep it handy where they can refer to it. Every statement made is in accordance with our own experience.

SWEET CLOVER: COMMON IN MANY PARTS OF THE COUNTRY: GAINING IN FAVOR AS A CULTIVATED CROP.

Sweet clover, which is so common along roadsides and in waste places in many parts of the country, is rapidly gaining in favor as a cultivated crop. This is due to its value for soil improvement, for pastures, and for hay. There are three species of sweet clover commonly found in the United States. The biennial yellow-flowered species (*Melilotus officinalis*) and the biennial white-flowered species (*Melilotus alba*) are valuable over a wide area, while the annual yellow-flowered species (*Melilotus indica*) is of little economic importance except in the extreme South and Southwest, where it is grown as a winter-cover and green-manure crop. With the exceptions of a few localities, white sweet clover is grown almost entirely. This is due to the fact that it yields more forage and produces larger roots than the other species. The white-flowered species is ordinarily referred to as sweet clover, while the other two species are called yellow sweet clover.

Sweet clover resembles alfalfa when young, but can be distinguished from it by its bitter taste, its smooth shiny leaves, and later, when in bloom, by the long, loose spike-like arrangement of white flowers in contrast to the dense purple clusters of alfalfa flowers. One of the most notable features of sweet clover is its root system. During the first season of growth the roots often reach a diameter of one-half inch at the crown of the plant. On account of the fleshy character of the roots, a large quantity of vegetable matter is added to the soil, even when the tops of the plants are removed for hay.

USES OF SWEET CLOVER.

There are few plants which will put waste land or run-down farms into condition for producing crops as quickly as sweet clover. Its value for this purpose is recognized in Alabama and Mississippi, and also in parts of Kentucky and Ohio. On account of the root development of this plant, large quantities of vegetable matter are added to the soil when a field of sweet clover is plowed. The root system alone has been estimated to be about 20 tons of green weight per acre for a good growth of sweet clover. In some parts of the country it has been used in a small way as a green-manure crop, the second year's growth being plowed under. By turning under a crop of sweet clover, or only the stubble, marked gains are obtained in the following crop.

Sweet clover is a very good winter-cover crop in that it prevents the soils from getting and sandier. It also takes up large quantities of available fertilizers which would probably leach out of the soil during the winter. On account of the large tap-roots of sweet-clover plants, potassium and phosphorus may be taken up in the subsoil and deposited, at

least in part, in the surface soil when the roots decay.

Since sweet clover is a biennial, like red clover, it is readily adapted to similar rotations. Sweet clover will undoubtedly prove to be a valuable crop as a substitute for red clover in the ordinary farm rotations where red clover will no longer grow. It may be seeded in the spring on grain as red clover is sown. When seeded in this manner some pasturage will be produced that fall in the North and pasturage or a hay crop in the South. The following season it produces two crops in the North and three crops in the South. It may be handled in a manner similar to red clover.

Sweet-clover hay is rapidly coming into favor as a feed for all classes of live stock, especially in places where more desirable types of hay will not grow successfully. Ordinarily some trouble is experienced in getting stock to eat sweet clover at first, on account of its bitter taste; but after they have been accustomed to eating it no trouble is experienced. A high percentage of digestible protein is contained in the hay.

Sweet clover makes excellent pasturage for horses, sheep, cattle, and hogs. Probably the easiest way to create an appetite for this plant is to commence pasturing stock on it very early in the spring of the second year, before other green feed has started. A sufficient number of animals should be kept in a sweet-clover pasture to keep it grazed rather closely. This will prevent the stems from becoming large and woody, and will also induce an abundant growth of young shoots. Stock when pastured upon sweet clover makes gains which compare very favorably with those obtained from either alfalfa or red clover.

There is very little danger of bloating when stock are pastured on sweet clover, but it is safest to avoid turning the stock into a sweet-clover pasture when it is wet with dew or rain, or when stock are unusually hungry. Sweet clover will also thrive well during midsummer drouth and produce much early and late pasturage.

SOIL REQUIREMENTS.

Sweet clover has the ability to thrive on poor clay soils as well as on poor sandy soils, but it will make a better growth on fertile soil. It prefers soils of limestone origin. Clay soils which are acid should be limed before sweet clover is sown. Sweet clover is also very resistant to alkali, and plants may be found in the West growing on soils so alkaline that little else than salt grass is able to survive.

The primary requisite for obtaining a stand of sweet clover is to have a firm, thoroughly compacted seed-bed with just enough loose soil on top to enable the seed to be covered. The lack of a firm seed-bed is probably the chief reason why sweet clover so often fails when seeded under cultivation. However, if it is seeded with spring-sown grain the seed-bed should be rolled after seeding. Better results are usually obtained where sweet clover is seeded alone in the late winter or spring on ground which has been plowed and thoroughly worked the previous fall.

SEEDING.

The time for seeding sweet clover varies considerably in different sections of the United States. In the eastern part, in the latitude of Washington, D. C., a good stand may be obtained by seeding either early in the spring or about August 15. One disadvantage with early fall seeding is that the plants mature and die the following year and only a small growth of roots is obtained. If seeded in spring in a nurse crop sweet clover will develop an extensive root system the first year and produce a small

amount of pasture. For this reason it is recommended that, so far as possible, it be seeded in the late winter or spring. In the southern states, as far north as the Ohio River, the practice is to seed quite early in the spring, during February or the early part of March. In the states further north the date is correspondingly later, until in Wisconsin it is usually seeded in the latter part of April or first of May. When the rainfall is sufficient, a stand can be obtained by seeding in small grain, such as fall wheat or spring-sown crops like oats and barley, but in seeding with grain one runs some risk of having the sweet-clover plants killed out by drouth during the summer. Owing to the rather slow germination of the seed it is usually best to seed at the rate of 15 to 20 pounds of hulled seed and 25 pounds of unhulled seed to the acre.

INOCULATION.

On poor soils, in localities where sweet clover is not common, it is quite important that the soil be inoculated at seeding time to insure good results. Even in localities where sweet clover is plentiful the early growth has been made much more vigorous by thoroughly inoculating the soil. Inoculation can be accomplished by mixing soil from a field where sweet clover, burr clover, yellow trefoil (black medic), or alfalfa grows abundantly, pound for pound, with sweet-clover seed. This mixture should be sown after sunset or on a cloudy day, and immediately harrowed in, since daylight greatly injures the inoculating germs. Inoculation is also accomplished in the South by using unhulled seed. Pure cultures of the inoculating bacteria may be obtained free of charge from the Department.

HARVESTING.

When hay is desired, sweet clover should be cut just before it begins to bloom. At this time the leaves are most abundant, and the stems have not yet become woody. Sweet-clover hay should be tedded while in the swath; and, just before the leaves become dry enough to shatter, it should be raked into windrows. After lying in the windrow for a day it may be put into shocks and cured. When sweet clover is seeded in the spring with a nurse crop, only a small amount of pasture is produced that autumn; but where it is seeded alone in the spring a cutting of hay may be made in the autumn. The following year a hay crop and a seed crop, or two cuttings of hay if seed is not desired, are usually obtained. In the South, where seeded alone, two cuttings may be obtained the first year, and either two cuttings of hay and a seed crop or three cuttings of hay the second year. Where seeded alone in the North there is no danger of the hay becoming woody the first year, and for that reason it does not need to be cut until it has attained its largest growth in the fall.

SEED PRODUCTION.

In harvesting the seed it is important that the plants be cut before the seed is fully matured. One must watch the seed crop carefully, and as soon as the lower racemes or spike-like arrangements of flowers are dry and mature it is best to cut the crop. Even where it is mown and the seed flailed out, probably not more than three-fourths of the racemes should be allowed to become fully mature. Sweet-clover seed can be thrashed most easily by the ordinary thrashing-machine; but if it is to be hulled a regular clover-huller with special rasps is used. In semi-arid and irrigated sections the hulls are so dry that an ordinary grain-thresher will remove most of them. Since the seed shatters very easily, sweet clover should be cut when it is wet with dew. If the first growth be cut for hay when it is 2½ feet tall, leaving a six-inch stubble, the seed crop will come on much more evenly. Care should be taken to cut the stubble of the preceding hay crops as high as possible, so that there will be sufficient stems remaining to resume growth, as this plant,

unlike alfalfa, does not form new crown shoots. Seed yields vary from two to eight bushels to the acre.

ERADICATION.

The failure of the farmers throughout the United States to make use of this valuable legume has largely been on account of the fear that it could not be eradicated from their farms if once started. The biennial nature of the plant makes the problem of eradication very easy. It will not persist when continually mowed so that it cannot produce seed, nor is it troublesome in clean cultivated or inter-tilled crops.

QUESTIONS ABOUT FLORIDA, DUCKS, CHICKENS, BEES, ETC.

1. Do you think that the raising of Indian Runner ducks in southern Florida is profitable—more particularly for eggs?

2. Were you called upon to decide whether you had better raise Indian Runners or any other breed of poultry that you might select as a source of income, which would it be?

3. In California there is a prejudice against duck eggs, hence the people that deal in eggs alone do not encourage one's raising ducks. Is this so in Florida?

4. What variety of fowls do you advise keeping in Florida—that is, if you wished to make eggs the leading feature of the enterprise?

5. What do you advise as a source of income in connection with Indian Runners or poultry—that is, for Florida, and if one had five to ten acres of land?

6. Do you advise keeping the white Indian Runners in Florida or the colored ones?

7. Does the warm country of southern Florida seem to affect unduly the Indian Runners?

8. Do you know of any section in southern Florida, east or west coast, where you think that one might profitably start an apiary? A friend once visited Sarasota, and was quite taken with the place. He also spoke of some near-by islands.

9. Will you please mention in the order of their importance such plants as are grown in Florida suitable for bees?

10. As a money-maker only, apart from any personal choice as to a place of residence, etc., do you consider California or Florida the best state—that is, suitable for bees?

11. What variety of bees do you consider the very best for Florida?

12. Were one starting the bee industry in Florida, would he do better to buy his apiary stock in that state, in Georgia, or some of the other states north of Florida?

13. A gentleman said to me the other day that he thought there was an overproduction of honey in this country. Is that so?

14. Does extracted alfalfa honey rank lower as a market product than other grades?

15. What about the orange-blossom as honey-producer?

16. About what proportion of our honey is exported?

San Jose, June 15.

1. The Indian Runner ducks are profitable in Florida when eggs are worth 40 or 50 cents a dozen; and as we get them to lay when the hens are laying little or none at all, the ducks do very well, especially if you have an opportunity to let them run in the canal as we do. If you are obliged to keep them confined, unless you use great care and economy their feed will cost more

than the eggs, when eggs are down to 20 cts., as they were last winter.

2, 3. I would select some other breed of poultry than ducks, because of the fact of the prejudice you mention in No. 3; and I think it's about the same in Florida as in California. People won't buy duck eggs, as a rule, unless there is a scarcity of hens' eggs and they are away up in price.

4. For eggs alone I think I would keep the Leghorns; but as the Rhode Island Reds for the past two winters have been laying, at moulting time, when eggs were 50 cts. a dozen, more than the Leghorns, I am not exactly decided.

5. I suppose the most money is made growing celery, lettuce, and other stuff to be shipped north; but this requires considerable capital, and the result is, perhaps, uncertain. As for myself, I have had more profit in growing potatoes, in connection with poultry, than any other garden crop; but I sold my potatoes right in town, of course, only in limited quantities. See back numbers of our journal.

6. My impression is that it makes little difference whether the ducks are white or colored; that is, where they are kept for eggs, and I should say the same in regard to chickens. The warm weather doesn't seem to trouble Indian Runners at all; in fact, they have no diseases so far as I know, and are never troubled with insects or vermin, unless it is the crocodiles where they run at large. See back numbers.

8. Sarasota is but a few miles from Bradentown, and the conditions are practically the same. The trouble with the island, and the greater part of Florida, in fact, is transportation, the distance from postoffice, etc.

9. There are no plants grown for bees in Florida that I know of. Of course, some honey comes from orange bloom, but oranges are grown for fruit and not honey.

10. I suppose more large yields of honey have been made in California than Florida; but it should be kept in mind that Florida has in years past also made some enormous yields; and California has also had quite a few seasons when the honey crop was almost a failure.

11. I believe the Italians are considered the best all-around bees in Florida as well as everywhere else.

12. I think I would buy bees to start with in Florida, so as to save transportation; and a few hives can be bought in almost any locality in the state.

13. An overproduction of good honey is something I never heard of as yet. I think there is no trouble in that direction.

14. Alfalfa honey is generally considered about equal to any, although there are some people who dislike its particular aroma.

15. Orange-blossom honey stands clear up to the top, or at least very near to the top, as to quality; but it's only occasionally that we have a good flow from orange bloom.

16. I am not prepared to answer; but my impression is that very little honey goes out of the United States. In Cuba, before the war, tons and tons of honey were sent to Germany and other foreign countries.

RAINBOW CORN AS A SUBSTITUTE FOR OSTRICH FEATHERS.

Dear Uncle Amos:—At a party that Elizabeth was invited to she wore a hair-band of a rainbow corn-leaf which grew in our garden. I thought you might like to know of a new use for rainbow corn.

Your niece,
DONNA SMITH.

Lakewood, O., Aug. 5.

Of course you have all heard of the cost of high living, referring particularly to "our daily bread;" and I think we are going to have something about the "high cost of dressing," especially when we consider the cost of some of the expensive millinery. The rainbow corn leaves would be, of course, but transient; but when the corn is at its best it would not be very much trouble to gather fresh leaves for every special occasion.

THE WRIGHT BROTHERS' FLYING-MACHINE FACTORY AT DAYTON, OHIO.

Ever since the Wright brothers succeeded in making a machine fly, I have given you occasional notes as the years have gone by. Just now I clip the following from the *Ohio Farmer*:

WRIGHT PLANT SOLD.

Orville Wright, aviator and aeroplane inventor, has sold his factory at Dayton to a syndicate of eastern capitalists. He now intends to give all of his time to scientific research along the lines of aviation.

It may be of interest to know that this Dayton factory is now quoted at something over a million dollars. I have been wondering if it were not possible that Orville Wright has sold out because he is averse to furnishing machines for war, as his father has been all his life a minister; and from what I know of the man I can readily imagine that he would be strongly averse to the manufacture of any machine designed for the purpose of killing people.

HEALTH NOTES

INTERNAL BATHING; FLUSHING THE COLON.

Our older readers will remember that toward twenty years ago I was greatly taken up with the "new water cure," as we called it, and I had some tracts published describing it, and, in fact, this whole thing was quite a fad at that time. But I soon discovered, with others, that, while flushing the colon with warm water would give instant relief in some cases, it was a great mistake—yes, a great blunder—to imagine that nature wanted us to hurry things up by a *daily* use of these applications of water or some substitute. Any one who has tried it will soon find his strength giving out, and I have been obliged to give a warning at various times ever since I was led into this piece of folly. Here is something from a young physician that hits the matter just about right.

Mr. Root:—I have gone so far in joining the "Bee Tribe" that I have acquired two swarms of Italians and the A B C, and have subscribed for GLEANINGS; and, strange as it may seem, I know enough to know that I don't know much about the bee part of it yet; but in the Health Notes I found that for which I had been long looking in vain (as people rarely are frank and helpful enough to publish any adverse testimony); viz., practical testimony as to the harm arising from following too far such a fad as the "internal bath."

There are conditions in which its limited use is no doubt beneficial; but if the wise Creator had intended that it should be always necessary or even good he would have provided us with a syringe attachment.

Most of our health fads have a germ of truth in them; but either their promoters hold the dollar so near that it covers all else for them, or they are seeing everything through one knot-hole; and any boy around the ball-park can tell you that you can't do that.

How much better it would be if we would apply a little skepticism, and seek knowledge until we are able to judge intelligently before following any of the "isms" faster or further than our reason can keep up with us, instead of blindly taking the word of some monomaniac or fellow who has something to sell!

How do we know that the contents of the bowels contain matter that is acting as a poison to the system? We don't. But we do know that they contain a lot of digested food ready for assimilation, and which the system needs. Who would be so foolish as to go to the expense and trouble of preparing food and then throw away what is not taken out at the first course?

How do we know that poisons are absorbed from the bowels? We do know that they are not, under any ordinary circumstances, but that there are some things that we need which are to be taken up by organs made to take them up, and to reject the refuse which the bowels will naturally throw off.

When we are ignorant of a matter, even if we know our ignorance, we hesitate to admit it, and find it easier to listen to the fellow who will make a lot of positive statements, and draw conclusions from them regardless of their truth, and be ruled by our imagination or his, than it is to question,

sufficient to be guided by our own reason. It is not always safe to admit the truth of a thing and follow it simply because, in our ignorance of the subject, it can be made to look plausible to us.

Chattanooga, Tenn.

F. C. FREEMAN.

VICTUALS AND DRINK; WHAT SHALL THEY BE? HOW TAKEN? ETC.

I am a clergyman, and have been taking GLEANINGS for a little more than a year. I am greatly interested in your Health Notes, for the reason that I am trying to win back my health. I notice that at your advanced age you keep in good health by strict observance of health laws, and carefulness in eating.

Would you be able to give an article on diet in which you describe or rather name the foods you eat, the number of meals per day, etc.? At the present time I am handling my own case of superacidity of the stomach; and I know from past experience that I shall get over it.

I fasted from all food about two days; drank plenty of water, and am now taking four quarts of milk daily when at home, drinking 6 ounces every half-hour. When visiting around the parish I take about a quart of milk at a meal. The milk is warmed, and is "chewed."

S. CLOWES NOXCON.

Winona, Ont., March 23.

My good friend, I should say you are about on the right track except in the great quantity of milk. Few people could stand as much; and taking it in small doses every half-hour I am sure would not agree with me at all. I greatly prefer eating nothing after three or four o'clock in the afternoon. You do not mention outdoor air and sunshine; and so far as a clear conscience is concerned, a minister of the gospel should, it would seem above all others, have that at all times, together with "the peace of God that passeth all understanding."

NERVOUSNESS—WHAT SHALL BE DONE FOR IT?

If Mr. A. I. Root could help me some I should be thankful. I am troubled with nervousness, and the doctor does not do me much good.

Cotton, Ill.

EVAN J. JONES.

My good friend, a little sleep when you are worried and nervous would be the first thing; and I would advise two meals a day, or two meals and a little fruit, say at four or five in the afternoon—nothing between meals until next morning, at breakfast. Your occupation should be outdoors, and you should have exercise enough to feel tired before you take any rest. If there is something that worries you, get rid of it if possible. If you have financial trouble, get rid of it. The loss of a little money or a little property is nothing compared with the loss of health. Strive to have a clear conscience void of offense before God and before your fellow-man.

POULTRY DEPARTMENT

THE INTELLIGENCE OF THE HEN; ALSO SOMETHING ABOUT CHICKEN HAWKS.

The letter below was received some years ago, before the trouble in Mexico. May God grant that a settlement may be near at hand, and that we may hear further from the writer.

At Xonduclia we care for 300 chickens, and we very seldom eat one—not because we do not appreciate the taste of their tender flesh as much as the hawks do, but because it is too much like eating the tender bodies of our own babies which we have oftentimes snatched from the outstretched hand of death, and in our bosoms hidden from his grasp. We sell our cockerels and let others slaughter and eat them. But on those rare occasions when we nerve ourselves to kill one at home we see to it that there be no race-witnesses to the regretful deed, while the victim himself knows not his impending fate, for a sack drawn over his head mercifully closes his eyes alike to the light of his departing day and to the uplifted ax that descends to destroy a bright intelligence and a pleasing personality.

Do we incline to believe a chicken has a soul? We do not know. Let our practice indicating a recognition of a visible degree of intelligence, of race consciousness, and ability to adapt itself to a changed environment, be our answer.

As to the intelligence of the hen, our observation shows it to be marvelous within the limit of its environment. We have seen chickens struggling sturdily with problems, trying in many ways to solve them. Certain emergencies a hen meets promptly and bravely. All is accounted for by "instinct," a word expressing only the ignorance of our forbears. Call it rather the accumulated tendency of successive generations to answer a question in its one and only answerable way. We have no hesitancy in asserting that the hen has intelligence of a rational character, and that it can arrive at correct conclusions within the limits of its ability to take correct observations. The hen (and her mate) has wonderful eyes, with remarkable accommodation—eyes capable of detecting the arch enemy, the hawk, when a mere speck in the sky, and equally well to recognize and pick up mere specks of food on the ground. I could tell you many an incident illustrative of the existence of indubitable intelligence in the hen—not the kind that would make her out a mere reflex machine or an automaton.

Once I bought a hen from a Mexican señora—evidently old (the hen), and sold because her days of usefulness were believed to be over. She proved to be an inveterate mother, and we soon named her "La gallina loco" (the Crazy Hen) because of her belligerent nature. I wish I knew and could portray the life of that hen during the years before she passed to my care. I know they were full of tragedies; that hawks and coyotes had embittered her life and accentuated the distrust of innumerable human aggressors. I could trace her confidence up to the point of picking up one of her family. She drew the line at that, and would attack with all the fury and ferocity of the mother robbed of her young, to the point of insanity. Once I gave her the family of a comrade mother, feeling inexpressible merriment when I did it, and she raised twenty-six. So you see that the idea that a hen is past her usefulness at two years of age will not pan out. We say that a hen of indolent age that has learned to be a good mother is worth several times over more than the pullet which takes her place. "Don't kill the laying

hen" is good advice; but "Don't kill the expert mother" is better.

The last family of the Crazy Hen consisted of eighteen. In our *prado*, or green, there is a mesquite bush around which I constructed an open circle of cordwood. This solitary refuge was immediately recognized and taken possession of by the Crazy Hen, and she and her family wisely kept within scouting distance of it. Nothing skyward escaped that mother hen's vigilant eye, old as it was. But the hawks had a way of sneaking down under cover of the seventy-foot cyanide tower, coming in sight only when on the downward fatal swoop.

Once a large hawk thus appeared over the family of eighteen. The crazy hen gave the signal to rush to cover, at the same time herself rushing furiously in line with the hawk to meet it as it neared the ground. The chicks were racing for and reaching the refuge; but one little belated fellow was seized just before the mother reached it with so furious an onslaught on the marauder that its flight was broken and it was obliged to drop the chick and make a run to get into the air again. After that the hawk kept circling at a great height for some minutes before he made off, the hen meantime watching his movements and signaling the chicks to lie low. We saw it all clearly—the hen maintaining a vigilant watch between where we stood and the refuge. At last, when the hawk was far distant, scarcely discernible, occurred the prettiest act of the entire drama, which only the intelligence and experience of the mother hen prevented being a tragedy. The hen gave a different signal, and immediately her family began streaming one by one out of the refuge, running like little white heads in a bee-line for their mother.* We counted them as they came out—seventeen; then there was a pause, and we thought the hawk had held on to the eighteenth and got away with it. We had all yelled involuntarily at the hawk when it first appeared. We had no gun, but we almost shouted when, a moment later, the wounded chick emerged and tried to run, but could not, though it bravely struggled at a walk to reach its mother. I went to meet it and found that one talon had gone through a wing, piercing the body; while another had punctured the crop. Notwithstanding its injuries, the wounded chick, rescued and afterward cared for

* This matter of the "signal" that the hen makes to call her chickens to run under cover, and another signal that they can come out as soon as the danger is past, is something wonderful. Human beings have to be taught to talk; but the baby chicks, like the honeybee, are born with an education—an education that is given by no teacher, but by the great God above. Wild fowls—the partridge, for instance—have the same wonderful vocabulary when danger threatens. This whole matter calls to mind vividly a fragment of an old letter that has just turned up. It was something I wrote to Mrs. Root when I was down on the island near Osprey. It is dated Jan. 7, 1907.

Dear Sue:—I ought to grow "fat," I have been laughing so hard at my pet chicks. As they have no mother, they not only chase after me, but they talk to me almost incessantly; and oh such pretty little baby talk it is! I am learning their language, and they are learning mine; and I am sure the loving Father is sending messages to me—messages of his great love to "even me" through these tiny little voices. When their feet get cold they come to me to "cuddle them up," and then I get, oh such pretty little contented and plaintive voices of thanks! Two have died; but I think through no fault of mine unless it was because I didn't understand the necessity of keeping those tiny little feet real warm. Of course I have lots more, but I am almost ashamed to tell you how hard it was to give up those two.

by its brave mother, got well, and was soon indispensable in the rapidly growing family.

After this, and, indeed, long before, we were ashamed for having named her so disrespectfully; and we said that, if she would permit it, we would tie a white ribbon to her wing and call her our "H. C. T. U." fighting mother—worthy exemplar or prototype of those saints with souls who are rapidly "inheriting the earth" after 45 years of faithful endeavor.

Tell me, friend Root, was the defense and attack of our ill-named Crazy Hen "the reflex action of an automatic machine" or was it not rather an exhibition of what in man is called prescience of mind, the prompt action of faculties inherited, sharpened, and developed by personal experience? That valiant mother had encountered hawks before—doubtless often fruitlessly; but, as in this case, also with results conservative of the race.

Is intelligence an attribute, a function of soul? Can there be soul without intelligence, without reason, without morality? What and *where* are the lines of definition?

"Morality in chickens! How absurd!" I hear some one say. I could, nevertheless, write an interesting chapter on the family relation of the poultry-yard. Immorality of poultry is the product of conditions created by man. The hen is by nature chaste and continent, seeking and giving her affections to one honored spouse only. It is a scandalous libel on the hen to call her an immoral (or un-moral) automaton. She is neither. That chapter in the psychology of the hen is one of the most pleasing, but it cannot be written now.

Force has no place in the training of young animals of any species. Mature animals with all their inherited and enviroic tendencies fully developed are not easy to subdue to the will of man. Force is effective only as it demonstrates man to be more powerful and resourceful, thus inspiring fear. But fear is a very unsafe basis for any relationship between man and the lower animals, since it arouses and accentuates the natural cunning of the animal, placing it constantly on the watch to take its trainer at a disadvantage. Such animals are not tamed at all. Another is a state of war instead of peace and good will between man and his victims.

Every animal, when it meets man, is an interrogation-point—the question scintillating its brain being, "Is he friend or foe?" There is scarcely more than a moment to reach a conclusion, and almost invariably the animal gives itself the benefit of the doubt, and flees or prepares to fight. He who would enjoy the companionship of the lower animals, whether bird or beast, must learn how to get a different answer to the opening question. Many animals are eager enough to establish friendly relations with man; but the latter is too unintelligent to understand their advances.

GEO. W. DITHRIDGE.

Vencedora, Chih., Mexico.

I wish to call particular attention to the two last paragraphs:

My experience is that domestic animals, especially chickens, after they find that you are really a friend to them, instead of an enemy, greatly enjoy friendly relations; and, as has often been said, the hen that lays the eggs is the happy hen; and when the fowls begin to understand that their owner is a *friend and protector*, they soon begin to enjoy companionship, and are delighted to see and meet their protector. I wish to emphasize, also, the point our friend

makes, that, when it is necessary to kill a fowl, do not let any of the rest of the flock witness what is going on. Running down a fowl, when one is all at once wanted for dinner, is bad and demoralizing all around. Take them quietly off the roost, if possible.

May God forgive *me* for having become vexed with sitting hens or hens with broods of chickens in times past; and may he help me to remember the good points presented in the letter above, when I am tempted again to become vexed with the chickens I love, down in my Florida home.

HUMBUGS AND SWINDLES

\$239,000,000 GONE TO SWINDLERS; THE "ELECTRO-CHEMICAL" FINGER-RING.

Our older readers will recall how we fought the "iron finger-ring" in years past in connection with "electropoise." See the following from the *Ohio Farmer* of Nov. 6:

During the past four years over 239 million dollars have been filched from the American public fraudulently. That is a big statement, but it represents only a part of the money that has been taken dishonestly during that period. It is merely the sum that federal officials have reported to have been so lifted. It has often been said that the American public is fraud-loving; it likes to be humbugged. But no matter how true that statement may have been at one stage of our history (and of the circus business) it is becoming more and more out of fashion with the passing years. The postoffice department has been largely instrumental in causing the decrease of fraud. In its effort to reduce this form of piracy the department has issued 56 fraud orders during the past year. These orders deny the use of the mails to the person or firm named. As a result of this policy of the department the number of fraudulent schemes has been greatly reduced, but still the aggregate is tremendous. The solicitor of the postoffice department states that one fraudulent concern had receipts of over \$350,000 last year. A certain "anti-fat" concern spent over \$50,000 in a single month in advertising, according to the same authority. Last year over 40,000 complaints and inquiries relative to frauds were received by the department and over 4000 cases were actually investigated. One of the most profitable fields seems to be that of working on the imagination and credulity of people who are in ill health. Inspectors report that one progressive Ohio manufacturer received \$46,500 from the sale of a metal "electro-chemical" finger-ring, which was sold for \$2 to some and \$1 to others. It was explained that inasmuch as certain diseases are caused by acid in the blood, they would be cured by wearing this ring, because the acid and the ring would create an electro-chemical action, causing the removal of the excess of acid! The diseases which the ring was intended to cure ranged from Bright's disease, St. Vitus dance, epileptic fits and spasms to adenoids, gout, and cancer. It would surely seem that there was considerable acid in the disposition of a man who would make such claims, the cure for which would rest in an iron ring about the ankle from which led a strong chain to a heavy iron ball. Beware of paying for things which are not understood. Beware of charms, wonderful cures, and investments said to make tremendous returns. The people behind such schemes are not in business for their health—at least not for the health of the investor.

Index to Gleanings in Bee Culture

Volume XLIII

In using this index the reader should not fail to note that it is divided into five departments, namely, General, Editorial, A. I. Root's writings, Contributors, and Illustrations. The index of General includes everything except Editorials, Illustrations, and A. I. Root's writings.

ON THE BOOKSHELF

Wealth from the Soil

When farm enthusiasts talk about the returns in farming for the educated man, they sometimes forget the fact that the profits are only for the man with an education related to the soil. Attending an agricultural college is not the only way in which the necessary information is to be obtained, however.

"Wealth from the Soil" (Forbes & Co., Chicago, \$1.00) is one means. This, and other books of its type, are making farming an exact science, more interesting and far less uncertain than it used to be.

The author, C. C. Bowsfield, shows the beginner how to select land, where to locate, what to pay, and how to equip and organize for money-making. With such information the book will save amateurs from serious mistakes.

His chapter on beekeeping, while necessarily elementary, is orthodox, and, like the other portions of the book, forms a basis upon which to build later experience and further reading.

George Washington, Farmer.

When a man achieves great distinction in one line of activity his brilliancy in others is often forgotten by posterity. John Hay, for example, had he not been Secretary of State, would have been remembered as a poet of merit. The career of George Washington as general of the continental armies and first president of the United States has so turned the attention of historians to these more striking accomplishments that his work as a farmer has been neglected.

Now comes an author, Paul Leland Haworth, who by patient research and personal visits to the scene of Washington's labors has uncovered a great deal of interesting information about the home and agricultural life of this, one of the greatest of American farmers. He shows that George Washington was a progressive agriculturist as well as the wealthiest American citizen of the eighteenth century.

Washington cultivated alfalfa on his farm in 1760. He was the first American to raise mules. He was one of the first to conserve the soil. On his estate at Mt. Vernon he performed hundreds of agricultural experiments. He made farming machinery with his own hands. He was a pioneer in improving breeds of stock. This volume is well illustrated with photographs, facsimiles of documents and a map of Mt. Vernon drawn by Washington himself. The book is handsomely bound, and makes a worthy

addition to any agricultural library as well as any historical. In fact, it is one of the few books which are necessary for the man who would know the history of agriculture.

"George Washington, Farmer," Paul Leland Haworth, 336 pages. The Bobbs-Merrill Co., Indianapolis, \$1.50 net.

Sweet Corn.

Among the valuable things which early settlers in this country received from the Indian inhabitants was sweet corn, a plant of strictly American origin. It has been profitably grown in gardens and truck-farms ever since. What would our meals be without it?

Now for the first time a practical and complete monograph on sweet-corn culture has been prepared. The author, Albert G. Wilkinson, of the Department of Vegetable Gardening, in the New York State College of Agriculture, treats the subject in detail as only a practical man engaged in sweet-corn growing can handle it.

Varieties, methods of culture, commercial growing, and processes of drying and canning, are completely covered. The book will appeal to the small farmer, market gardener, and suburban grower.

"Sweet Corn," Albert G. Wilkinson, 203 pages. The Orange Judd Co., New York, 75 cts. net.

Mushroom-growing.

What boy has never known the keen joy of gathering mushrooms on a warm day in spring? As we remember it, even fishing was hardly equal to the sport of hunting for the lowly fungi. On the table nothing was ever finer than the mushrooms we had ourselves gathered, unless possibly it was the honey from our own hives.

B. M. Duggar, of the Missouri Botanical Garden, is the author of a volume, "Mushroom Growing," just published. Here are the requirements for growing mushrooms at home, making it entirely unnecessary, if one has the facilities, to depend on chance discoveries in pastures or wood-lots. He shows how mushroom-growing can be placed upon a paying commercial basis, especially if one lives near a good-sized market.

The author has spent many years in extended observations upon the best practices of the mushroom-growers of the present time. For the past fifteen years he has had wide experience with experimental and commercial production. The information contained in the book is therefore reliable, definite, up-to-date, and comprehensive.

"Mushroom Growing," B. M. Duggar, 250 pages. The Orange Judd Co., New York, \$1.50.
